FileWriteStruct

The function writes into a bin-file contents of a structure passed as a parameter, starting from the current position of the file pointer.

```
uint FileWriteStruct(
    int          file_handle,      // File handle
    const void&  struct_object,    // link to an object
    int          size=-1           // size to be written in bytes
);
```

Parameters

file_handle

[in] File descriptor returned by [FileOpen\(\)](#).

struct_object

[in] Reference to the object of this structure. The structure should not contain strings, [dynamic arrays](#) or [virtual functions](#).

size=-1

[in] Number of bytes that you want to record. If size is not specified or the specified number of bytes is greater than the size of the structure, the entire structure is written.

Return Value

If successful the function returns the number of bytes written. The file pointer is shifted by the same number of bytes.

Example:

```

[Structures and classes](#)

FileLoad

Reads all data of a specified binary file into a passed array of numeric types or simple structures. The function allows you to quickly read data of a known type into the appropriate array.

```
bool FileLoad(
    int          file_name,           // File name
    const void&  buffer[],           // An array of numeric types or simple structures
    int          common_flag=0       // A file flag, is searched in <data_folder>\MQL5\
);
```

Parameters

file_name

[in] The name of the file from which data will be read.

buffer

[out] An array of numeric types or [simple structures](#).

common_flag=0

[in] [A file flag](#) indicating the operation mode. If the parameter is not specified, the file is searched in the subfolder MQL5\Files (or in <testing_agent_directory>\MQL5\Files in case of testing).

Return Value

The number of elements read or -1 in case of an error.

Note

The FileLoad() function reads from a file the number of bytes multiple of the array element size. Suppose the file size is 10 bytes, and the function reads data into an array of type double ([sizeof](#)(double)=8). In this case the function will read only 8 bytes, the remaining 2 bytes at the end of the file will be dropped, and the function FileLoad() will return 1 (1 element read).

Example:

```
//+-----+
//|                                     Demo_FileLoad.mq5 |

FileSave

Writes to a binary file all elements of an array passed as a parameter. The function allows you to quickly write arrays of numeric types or simple structures as one string.

```
bool FileSave(
    int          file_name,           // File name
    const void&  buffer[],           // An array of numeric types or simple structures
    int          common_flag=0       // A file flag, by default files are written to <default_directory>
);
```

Parameters

file_name

[in] The name of the file, to the data array will be written.

buffer

[in] An array of numeric types or [simple structures](#).

common_flag=0

[in] [A file flag](#) indicating the operation mode. If the parameter is not specified, the file will be written to the subfolder MQL5\Files (or to <testing_agent_directory>\MQL5\Files in case of testing).

Return Value

In case of failure returns false.

Example:

```
//+-----+
//|                                     Demo_FileSave.mq5 |

FolderCreate

The function creates a folder in the Files directory (depending on the value of `common_flag`).

```
bool FolderCreate(
    string  folder_name,      // String with the name of the new folder
    int     common_flag=0     // Scope
);
```

Parameters

folder_name

[in] The name of the directory you want to create. Contains the full path to the folder.

common_flag=0

[in] [Flag](#) determining the location of the directory. If `common_flag=FILE_COMMON`, then the directory is in the shared folder for all client terminals `\Terminal\Common\Files`. Otherwise, the directory is in a local folder (`MQL5\Files` or `MQL5\Tester\Files` in case of testing).

Return Value

Returns true if successful, otherwise - false.

Note

For security reasons, work with files is strictly controlled in the MQL5 language. Files with which file operations are conducted using MQL5 means, cannot be outside the file sandbox.

Example:

```
//+-----+
//|                                     Demo_FolderCreate.mq5 |

```

See also

[FileOpen\(\)](#), [FolderClean\(\)](#), [FileCopy\(\)](#)

FolderDelete

The function removes the specified directory. If the folder is not empty, then it can't be removed.

```
bool FolderDelete(
    string  folder_name,      // String with the name of the folder to delete
    int     common_flag=0     // Scope
);
```

Parameters

folder_name

[in] The name of the directory you want to delete. Contains the full path to the folder.

common_flag=0

[in] [Flag](#) determining the location of the directory. If `common_flag=FILE_COMMON`, then the directory is in the shared folder for all client terminals `\Terminal\Common\Files`. Otherwise, the directory is in a local folder (`MQL5\Files` or `MQL5\Tester\Files` in the case of testing).

Return Value

Returns true if successful, otherwise false.

Note

For security reasons, work with files is strictly controlled in the MQL5 language. Files with which file operations are conducted using MQL5 means, cannot be outside the file sandbox.

If the directory contains at least one file and/or subdirectory, then this directory can't be deleted, it must be cleared first. [FolderClean\(\)](#) is used to clear a folder of all its files or subfolders.

FolderClean

The function deletes all files in a specified folder.

```
bool FolderClean(
    string folder_name,      // String with the name of the deleted folder
    int common_flag=0       // Scope
);
```

Parameters

folder_name

[in] The name of the directory where you want to delete all files. Contains the full path to the folder.

common_flag=0

[in] [Flag](#) determining the location of the directory. If common_flag = FILE_COMMON, then the directory is in the shared folder for all client terminals \Terminal\Common\Files. Otherwise, the directory is in a local folder(MQL5\Files or MQL5\Tester\Files in case of testing).

Return Value

Returns true if successful, otherwise false.

Note

For security reasons, work with files is strictly controlled in the MQL5 language. Files with which file operations are conducted using MQL5 means, cannot be outside the file sandbox.

This function should be used with caution, since all the files and all subdirectories are deleted irretrievably.

Example:

```

Custom Indicators

This is the group functions used in the creation of custom indicators. These functions can't be used when writing Expert Advisors and Scripts.

Function	Action
SetIndexBuffer	Binds the specified indicator buffer with one-dimensional dynamic array of the double type
IndicatorSetDouble	Sets the value of an indicator property of the double type
IndicatorSetInteger	Sets the value of an indicator property of the int type
IndicatorSetString	Sets the value of an indicator property of the string type
PlotIndexSetDouble	Sets the value of an indicator line property of the type double
PlotIndexSetInteger	Sets the value of an indicator line property of the int type
PlotIndexSetString	Sets the value of an indicator line property of the string type
PlotIndexGetInteger	Returns the value of an indicator line property of the integer type

[Indicator properties](#) can be set using the compiler directives or using functions. To better understand this, it is recommended that you study [indicator styles in examples](#).

All the necessary calculations of a custom indicator must be placed in the predetermined function [OnCalculate\(\)](#). If you use a short form of the OnCalculate() function call, like

```
int OnCalculate (const int rates_total, const int prev_calculated, const int begin, co
```

then the *rates_total* variable contains the value of the total number of elements of the price[] array, passed as an input parameter for calculating indicator values.

Parameter *prev_calculated* is the result of the execution of OnCalculate() at the previous call; it allows organizing a saving algorithm for calculating indicator values. For example, if the current value *rates_total* = 1000, *prev_calculated* = 999, then perhaps it's enough to make calculations only for one value of each indicator buffer.

If the information about the size of the input array price would have been unavailable, then it would lead to the necessity to make calculations for 1000 values of each indicator buffer. At the first call of OnCalculate() value *prev_calculated* = 0. If the price[] array has changed somehow, then in this case *prev_calculated* is also equal to 0.

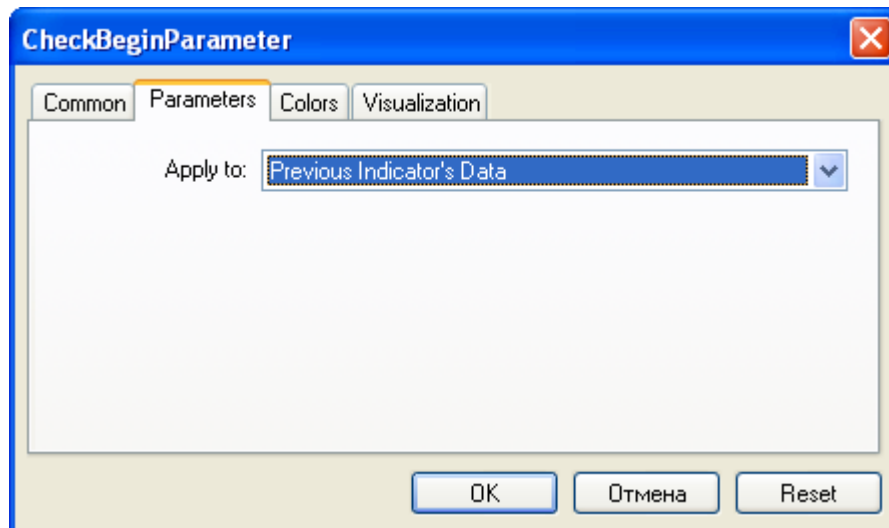

The *begin* parameter shows the number of initial values of the price array, which don't contain data for calculation. For example, if values of Accelerator Oscillator (for which the first 37 values aren't

calculated) were used as an input parameter, then begin = 37. For example, let's consider a simple indicator:

```
#property indicator_chart_window
#property indicator_buffers 1
#property indicator_plots 1
//---- plot Label1
#property indicator_label1 "Label1"
#property indicator_type1 DRAW_LINE
#property indicator_color1 clrRed
#property indicator_style1 STYLE_SOLID
#property indicator_width1 1
//--- indicator buffers
double Label1Buffer[];
//+-----+
//| Custom indicator initialization function |
//+-----+
void OnInit()
{
//--- indicator buffers mapping
SetIndexBuffer(0,Label1Buffer,INDICATOR_DATA);
//---
}
//+-----+
//| Custom indicator iteration function |
//+-----+
int OnCalculate(const int rates_total,
               const int prev_calculated,
               const int begin,
               const double &price[])

{
//---
Print("begin = ",begin," prev_calculated = ",prev_calculated," rates_total = ",rates_total);
//--- return value of prev_calculated for next call
return(rates_total);
}
```

Drag it from the "Navigator" window to the window of the Accelerator Oscillator indicator and we indicate that calculations will be made based on the values of the previous indicator:

As a result, the first call of `OnCalculate()` the value of `prev_calculated` will be equal to zero, and in further calls it will be equal to the `rates_total` value (until the number of bars on the price chart increases).

The value of the `begin` parameter will be exactly equal to the number of initial bars, for which the values of the Accelerator indicator aren't calculated according to the logic of this indicator. If we look at the source code of the custom indicator `Accelerator.mq5`, we'll see the following lines in the `OnInit()` function:

```
//--- sets first bar from which index will be drawn
PlotIndexSetInteger(0, PLOT_DRAW_BEGIN, 37);
```

Using the function [PlotIndexSetInteger](#)(0, [PLOT_DRAW_BEGIN](#), empty_first_values), we set the number of non-existing first values in the zero indicator array of a custom indicator, which we don't need to accept for calculation (empty_first_values). Thus, we have mechanisms to:

1. set the number of initial values of an indicator, which shouldn't be used for calculations in another custom indicator;
2. get information on the number of first values to be ignored when you call another custom indicator, without going into the logic of its calculations.

Indicator Styles in Examples

The MetaTrader 5 Client Terminal includes 38 technical indicators that can be used in MQL5 programs using [appropriate functions](#). But the main advantage of the MQL5 language is the ability to create custom indicators, which can then be used in Expert Advisors or simply applied on price charts for the purpose of technical analysis.

The entire set of indicators can be derived from several base [drawing styles](#), known as plotting. Plotting denotes a way of displaying data, which the indicator calculates, stores and provides on request. There are seven such basic plotting types:

1. A line
2. A section (segment)
3. Histogram
4. Arrow (symbol)
5. A painted area (filled channel)
6. Bars
7. Japanese candlesticks

Each plotting requires one to five [arrays](#) of the [double](#) type, in which indicator values are stored. For the purpose of convenience, these arrays are associated with the indicator buffers. The number of buffers in an indicator must be declared in advance using [compiler directives](#), for example:

```
#property indicator_buffers 3 // Number of buffers
#property indicator_plots 2 // number of plots
```

The number of buffers in the indicator is always greater than or equal to the number of plots in the indicator.

Since each basic plotting type can have color variation or construction specifics, the actual number of plotting types in the MQL5 is 18:

Plotting	Description	Value buffers	Color buffers
DRAW_NONE	Is not visually displayed in the chart, but the values of the corresponding buffer can be viewed in the Data Window	1	-
DRAW_LINE	A line is plotted on the values of the corresponding buffer (empty values in the buffer are undesirable)	1	-
DRAW_SECTION	Is drawn as line segments between the values of the corresponding buffer	1	-

	(usually has a lot of empty values)		
<u>DRAW_HISTOGRAM</u>	Is drawn as a histogram from the zero line to the values of the corresponding buffer (may have empty values)	1	-
<u>DRAW_HISTOGRAM2</u>	Is drawn as a histogram based on two indicator buffers (may have empty values)	2	-
<u>DRAW_ARROW</u>	Is drawn as symbols (may have empty values)	1	-
<u>DRAW_ZIGZAG</u>	Similar to the style <u>DRAW_SECTION</u> , but unlike it, can plot vertical segments on one bar	2	-
<u>DRAW_FILLING</u>	Color fill between two lines. 2 values of the corresponding buffers are shown in the Data Window	2	-
<u>DRAW_BARS</u>	Is drawn as bars. 4 values of the corresponding buffers are shown in the Data Window	4	-
<u>DRAW_CANDLES</u>	Drawn as Japanese candlesticks. 4 values of the corresponding buffers are shown in the Data Window	4	-
<u>DRAW_COLOR_LINE</u>	A line for which you can alternate colors on different bars or change its color at any time	1	1
<u>DRAW_COLOR_SECTION</u>	Similar to the style <u>DRAW_SECTION</u> , but the color of each section can be set	1	1

	individually; color can also be set dynamically		
<u>DRAW_COLOR_HISTOGRAM</u>	Similar to the style <u>DRAW_HISTOGRAM</u> , but each strip may have a different color, you can set the color dynamically	1	1
<u>DRAW_COLOR_HISTOGRAM2</u>	Similar to the style <u>DRAW_HISTOGRAM2</u> , but each strip may have a different color, you can set the color dynamically	2	1
<u>DRAW_COLOR_ARROW</u>	Similar to the style <u>DRAW_ARROW</u> , but each symbol can have its color. Color can be changed dynamically	1	1
<u>DRAW_COLOR_ZIGZAG</u>	The <u>DRAW_ZIGZAG</u> style with the options of individual coloring of sections and dynamic color changing	2	1
<u>DRAW_COLOR_BARS</u>	The <u>DRAW_BARS</u> style with the options of individual coloring of bars and dynamic color changing	4	1
<u>DRAW_COLOR_CANDLES</u>	The <u>DRAW_CANDLES</u> style with the options of individual coloring of candlesticks and dynamic color changing	4	1

The difference between an indicator buffer and an array

In each indicator, on its [global level](#), you should declare one or more arrays of the double type, which then must be used as an indicator buffer using the [SetIndexBuffer\(\)](#) function. To draw indicator plots, only the values of the indicator buffers are used, any other arrays cannot be used for this purpose. In addition, buffer values are displayed in the Data Window.

An indicator buffer should be [dynamic](#) and does not require [specification of the size](#) - the size of the array used as the indicator buffer is set by the terminal execution subsystem automatically.

After the array is bound to the indicator buffer, [the indexing direction](#) is set by default like in ordinary arrays, but you can use the [ArraySetAsSeries\(\)](#) function to change the way of access to the array elements. By default, the indicator buffer is used to store data used for plotting ([INDICATOR_DATA](#)).

If the calculation of indicator values requires holding intermediate calculations and storing the additional values for each bar, then such an array can be declared as a calculation buffer during binding ([INDICATOR_CALCULATIONS](#)). For the intermediate values, you can also use a regular array, but in this case, the programmer has to manage the size of the array.

Some plots allow setting a color for each bar. To store the information about color, color buffers are used ([INDICATOR_COLOR_INDEX](#)). The color is an integer type [color](#), but all indicator buffers must be of type [double](#). Values of color and auxiliary ([INDICATOR_CALCULATIONS](#)) buffers cannot be obtained by using [CopyBuffer\(\)](#).

The number of indicator buffers must be specified using the compiler directive `#property indicator_buffers` number_of_buffers:

```
#property indicator_buffers 3 // the indicator has 3 buffers
```

The maximum allowed number of buffers in one indicator is 512.

Relevance of Indicator Buffers and Plotting

Each plotting is based on one or more indicator buffers. So, for displaying simple candlesticks, four values are required - Open, High, Low and Close prices. Accordingly, to display an indicator in the form of candlesticks, it is necessary to declare 4 indicator buffers and 4 arrays of the double type for them. For example:

```
//--- The indicator has four indicator buffers
#property indicator_buffers 4
//--- The indicator has one plotting
#property indicator_plots 1
//--- Graphical plotting number 1 will appear as candlesticks
#property indicator_type1 DRAW_CANDLES
//--- Candlestick will be drawn in clrDodgerBlue
#property indicator_color1 clrDodgerBlue
//--- 4 arrays for the indicator buffers
double OBuffer[];
double HBuffer[];
double LBuffer[];
double CBuffer[];
```

Graphical plots automatically use indicator buffers in accordance with the plot number. Numbering of plots starts with 1, numbering of buffers starts with zero. If the first plotting requires 4 indicator buffers, then the first 4 indicator buffers will be used to draw it. These four buffers should be linked with the appropriate arrays with correct indexing using the [SetIndexBuffer\(\)](#) function.

```
//--- Binding arrays with indicator buffers
SetIndexBuffer(0,OBuffer,INDICATOR_DATA); // The first buffer corresponds to the O
```

```
SetIndexBuffer(1,HBuffer,INDICATOR_DATA); // The second buffer corresponds to inde
SetIndexBuffer(2,LBuffer,INDICATOR_DATA); // The third buffer corresponds to inde
SetIndexBuffer(3,CBuffer,INDICATOR_DATA); // The fourth buffer corresponds to inde
```

The plotting candlesticks, the indicator will use just the first four buffers, because plotting of "candlesticks" was announced under the first number.

Change the example, and add plotting of a simple line - [DRAW_LINE](#). Now suppose that the line is numbered 1, and the candlesticks are number 2. The number of buffers and the number of plots has increased.

```
//--- The indicator has 5 indicator buffers
#property indicator_buffers 5
//--- The indicator has 2 plots
#property indicator_plots 2
//--- Plot 1 is a line
#property indicator_type1 DRAW_LINE
//--- The color of the line is clrDodgerRed
#property indicator_color1 clrDodgerRed
//--- Plot 2 is drawn as Japanese candlesticks
#property indicator_type2 DRAW_CANDLES
//--- The color of the candlesticks is clrDodgerBlue
#property indicator_color2 clrDodgerBlue
//--- 5 arrays for indicator buffers
double LineBuffer[];
double OBuffer[];
double HBuffer[];
double LBuffer[];
double CBuffer[];
```

The order of the plots has changed, and now the line comes first, followed by Japanese candlesticks. Therefore, the order of the buffers is appropriate - first we announce a buffer for the line with the zero index, and then four buffers for the candlesticks.

```
SetIndexBuffer(0,LineBuffer,INDICATOR_DATA); // The first buffer corresponds to in
//--- Binding arrays with indicator buffers for the candlesticks
SetIndexBuffer(1,OBuffer,INDICATOR_DATA); // The second buffer corresponds to i
SetIndexBuffer(2,HBuffer,INDICATOR_DATA); // The third buffer corresponds to in
SetIndexBuffer(3,LBuffer,INDICATOR_DATA); // The fourth buffer corresponds to i
SetIndexBuffer(4,CBuffer,INDICATOR_DATA); // The fifth buffer corresponds to in
```

The number of buffers and plots can be set only by using compiler directives, it is impossible to change these properties dynamically using functions.

Color Versions of Styles

As can be seen in the table, the styles are divided into two groups. The first group includes styles in whose name there is no word **COLOR**, we call these styles basic:

- DRAW_LINE
- DRAW_SECTION
- DRAW_HISTOGRAM
- DRAW_HISTOGRAM2
- DRAW_ARROW
- DRAW_ZIGZAG
- DRAW_FILLING
- DRAW_BARS
- DRAW_CANDLES

In the second group, the style names contain the word **COLOR**, let's call them color versions:

- DRAW_COLOR_LINE
- DRAW_COLOR_SECTION
- DRAW_COLOR_HISTOGRAM
- DRAW_COLOR_HISTOGRAM2
- DRAW_COLOR_ARROW
- DRAW_COLOR_ZIGZAG
- DRAW_COLOR_BARS
- DRAW_COLOR_CANDLES

All color versions of styles differ from the basic ones in that they allow specifying a color for each part of the plotting. The minimal part of plotting is a bar, so we can say that the color versions allow setting the color on each bar.

Exceptions are styles [DRAW_NONE](#) and [DRAW_FILLING](#), they do not have color versions.

To set the plotting color on each bar, an additional buffer for storing the color index has been added to the color version. These indices indicate the number of a color in a special array, which contains a predefined set of colors. The size of the array of colors is 64. This means that each color version of a style allows painting a plot in 64 different colors.

The set and the number of colors in the special array of colors can be set via a compiler directive `#property indicator_color`, where you can specify all the necessary colors separated by commas. For example, such an entry in an indicator:

```
//--- Define 8 colors for coloring candlesticks (they are stored in the special array)
#property indicator_color1 clrRed,clrBlue,clrGreen,clrYellow,clrMagenta,clrCyan,clrL
```

It states that for plotting 1, 8 colors are set, which will be placed in a special array. Further in the program we will not specify the color of the plotting, but only its index. If we want to set red color for the bar number **K**, the color index value from an array should be set in the color buffer of the indicator. The red color is specified first in the directive, it corresponds to the index number 0.

```
//--- set the candlestick color clrRed
col_buffer[buffer_index]=0;
```

The set of colors is not given once and for all, it can be changed dynamically using `PlotIndexSetInteger()`. Example:

```
//--- Set the color for each index as the property PLOT_LINE_COLOR
PlotIndexSetInteger(0,           // The number of a graphical style
                    PLOT_LINE_COLOR, // Property identifier
                    plot_color_ind, // The index of the color, where we v
                    color_array[i]); // A new color
```

Properties of the indicator and plotting

For indicator plots, properties can be set by means of [compiler directives](#) and using the appropriate functions. Read more information about this in [Connection between Indicator Properties and Functions](#). Dynamic change of indicator properties using special functions allows creating more flexible custom indicators.

Start of Indicator Drawing on the Chart

In many cases, according to the conditions of the algorithm, it is impossible to start calculating the indicator values immediately with the current bar, since it is necessary to provide a minimum number of previous bars available in history. For example, many types of smoothing imply using an array of prices over the previous N bars, and on the basis of these values, the indicator value on the current bar is calculated.

In such cases, either there is no way to calculate the indicator values for the first N bars, or these values are not intended to be displayed on the chart and are only subsidiary for calculating further values. To avoid plotting of the indicator on the first N bars of the history, set the N value to the [PLOT_DRAW_BEGIN](#) property for the corresponding plot:

```
//--- Binding arrays with indicator buffers for the candlesticks
PlotIndexSetInteger(number_of_plot, PLOT_DRAW_BEGIN, N);
```

Here:

- number_of_plot - a value from zero to indicator_plots-1 (numbering of plots starts with zero).
- N - the number of first bars in the history, on which the indicator should not be displayed on the chart.

DRAW_NONE

The DRAW_NONE style is designed for use in cases where it is necessary to calculate the values of a buffer and show them in the Data Window, but plotting on the chart is not required. To set up the accuracy use the expression `IndicatorSetInteger(INDICATOR_DIGITS,num_chars)` in the [OnInit\(\)](#) function:

```
int OnInit()
{
    //--- indicator buffers mapping
    SetIndexBuffer(0,InvisibleBuffer,INDICATOR_DATA);
    //--- Set the accuracy of values to be displayed in the Data Window
    IndicatorSetInteger(INDICATOR_DIGITS,0);
    //---
    return(INIT_SUCCEEDED);
}
```

The number of buffers required for plotting DRAW_NONE is 1.

An example of the indicator that shows the number of the bar on which the mouse currently hovers in the Data Window. The numbering corresponds to the timeseries, meaning the current unfinished bar has the zero index, and the oldest bar has the largest index.

Note that despite the fact that, for red color is set plotting #1, the indicator does not draw anything on the chart.

    for(int i=0;i<total;i++) InvisibleBuffer[i]=i;
}

```

DRAW_LINE

DRAW_LINE draws a line of the specified color by the values of the indicator buffer. The width, style and color of the line can be set using the [compiler directives](#) and dynamically using the [PlotIndexSetInteger\(\)](#) function. Dynamic changes of the plotting properties allows "to enliven" indicators, so that their appearance changes depending on the current situation.

The number of buffers required for plotting DRAW_LINE is 1.

An example of the indicator that draws a line using Close prices of bars. The line color, width and style change randomly every N=5 ticks.

Note that initially for `plot1` with DRAW_LINE the properties are set using the compiler directive [#property](#), and then in the [OnCalculate\(\)](#) function these three properties are set randomly. The N parameter is set in [external parameters](#) of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

    Comment(comm);
}
```

DRAW_SECTION

DRAW_SECTION draws sections of the specified color by the values of the indicator buffer. The width, color and style of the line can be specified like for the [DRAW_LINE](#) style - using [compiler directives](#) or dynamically using the [PlotIndexSetInteger\(\)](#) function. Dynamic changes of the plotting properties allows "to enliven" indicators, so that their appearance changes depending on the current situation.

Sections are drawn from one non-empty value to another non-empty value of the indicator buffer, empty values are ignored. To specify what value should be considered as "empty", set this value in the [PLOT_EMPTY_VALUE](#) property: For example, if the indicator should be drawn as a sequence of sections on non-zero values, then you need to set the zero value as an empty one:

```
//--- The 0 (empty) value will not participate in drawing
PlotIndexSetDouble(index_of_plot_DRAW_SECTION,PLOT_EMPTY_VALUE,0);
```

Always explicitly fill in the values of the indicator buffers, set an empty value in a buffer to the elements that should not be plotted.

The number of buffers required for plotting DRAW_SECTION is 1.

An example of the indicator that draws sections between the High and Low prices. The color, width and style of all sections change randomly every N ticks.

Note that initially for plot1 with DRAW_SECTION the properties are set using the compiler directive [#property](#), and then in the [OnCalculate\(\)](#) function these three properties are set randomly. The N parameter is set in [external parameters](#) of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

DRAW_HISTOGRAM

The DRAW_HISTOGRAM style draws a histogram as a sequence of columns of a specified color from zero to a specified value. Values are taken from the indicator buffer. The width, color and style of the column can be specified like for the [DRAW_LINE](#) style - using [compiler directives](#) or dynamically using the [PlotIndexSetInteger\(\)](#) function. Dynamic changes of the plotting properties allows changing the look of the histogram based on the current situation.

Since a column from the zero level is drawn on each bar, DRAW_HISTOGRAM should better be used in a separate chart window. Most often this type of plotting is used to create indicators of the oscillator type, for example, [Bears Power](#) or [OsMA](#). For the empty non-displayable values the zero value should be specified.

The number of buffers required for plotting DRAW_HISTOGRAM is 1.

An example of the indicator that draws a sinusoid of a specified color based on the [MathSin\(\) function](#). The color, width and style of all histogram columns change randomly each N ticks. The bars parameter specifies the period of the sinusoid, that is after the specified number of bars the sinusoid will repeat the cycle.

Note that initially for plot1 with DRAW_HISTOGRAM the properties are set using the compiler directive [#property](#), and then in the [OnCalculate\(\)](#) function these three properties are set randomly. The N parameter is set in [external parameters](#) of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

DRAW_HISTOGRAM2

The DRAW_HISTOGRAM2 style draws a histogram of a specified color - vertical segments using the values of two indicator buffers. The width, color and style of the segments can be specified like for the [DRAW_LINE](#) style - using [compiler directives](#) or dynamically using the [PlotIndexSetInteger\(\)](#) function. Dynamic changes of the plotting properties allows changing the look of the histogram based on the current situation.

The DRAW_HISTOGRAM2 style can be used in a separate subwindow of a chart and in its main window. For empty values nothing is drawn, all the values in the indicator buffers need to be set explicitly. Buffers are not initialized with a zero value.

The number of buffers required for plotting DRAW_HISTOGRAM2 is 2.

An example of the indicator that plots a vertical segment of the specified color and width between the Open and Close prices of each bar. The color, width and style of all histogram columns change randomly each N ticks. During the start of the indicator, in the [OnInit\(\)](#) function, the number of the day of week for which the histogram will not be drawn - invisible_day - is set randomly. For this purpose an empty value is set [PLOT_EMPTY_VALUE=0](#):

```
//--- Set an empty value
PlotIndexSetDouble(index_of_plot_DRAW_SECTION,PLOT_EMPTY_VALUE,0);
```

Note that initially for plot1 with DRAW_HISTOGRAM2 the properties are set using the compiler directive [#property](#), and then in the [OnCalculate\(\)](#) function these three properties are set randomly. The N parameter is set in [external parameters](#) of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

```

DRAW_ARROW

The DRAW_ARROW style draws arrows of the specified color (symbols of the set [Wingdings](#)) based on the value of the indicator buffer. The width and color of the symbols can be specified like for the [DRAW_LINE](#) style - using [compiler directives](#) or dynamically using the [PlotIndexSetInteger\(\)](#) function. Dynamic changes of the plotting properties allows changing the look of an indicator based on the current situation.

The symbol code is set using the [PLOT_ARROW](#) property.

```
//--- Define the symbol code from the Wingdings font to draw in PLOT_ARROW  
PlotIndexSetInteger(0,PLOT_ARROW,code);
```

The default value of PLOT_ARROW=159 (a circle).

Each arrow is actually a symbol that has the height and the anchor point, and can cover some important information on a chart (for example, the closing price at the bar). Therefore, we can additionally specify the vertical shift in pixels, which does not depend on the scale of the chart. The arrows will be shifted down by the specified number of pixels, although the values of the indicator will remain the same:

```
//--- Set the vertical shift of arrows in pixels  
PlotIndexSetInteger(0,PLOT_ARROW_SHIFT,shift);
```

A negative value of PLOT_ARROW_SHIFT means the shift of arrows upwards, a positive values shifts the arrow down.

The DRAW_ARROW style can be used in a separate subwindow of a chart and in its main window. Empty values are not drawn and do not appear in the "Data Window", all the values in the indicator buffers should be set explicitly. Buffers are not initialized with a zero value.

```
//--- Set an empty value  
PlotIndexSetDouble(index_of_plot_DRAW_ARROW,PLOT_EMPTY_VALUE,0);
```

The number of buffers required for plotting DRAW_ARROW is 1.

An example of the indicator, which draws arrows on each bar with the close price higher than the close price of the previous bar. The color, width, shift and symbol code of all arrows are changed randomly every N ticks.

In the example, for `plot1` with the `DRAW_ARROW` style, the properties, color and size are specified using the compiler directive `#property`, and then in the `OnCalculate()` function the properties are set randomly. The `N` parameter is set in [external parameters](#) of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

DRAW_ZIGZAG

The DRAW_ZIGZAG style draws segments of a specified color based on the values of two indicator buffers. This style is very similar to [DRAW_SECTION](#), but unlike the latter, it allows drawing vertical segments within one bar, if values of both indicator buffers are set for this bar. The segments are plotted from a value in the first buffer to a value in the second indicator buffer. None of the buffers can contain only empty values, since in this case nothing is plotted.

The width, color and style of the line can be specified like for the [DRAW_SECTION](#) style - using [compiler directives](#) or dynamically using the [PlotIndexSetInteger\(\)](#) function. Dynamic changes of the plotting properties allows "to enliven" indicators, so that their appearance changes depending on the current situation.

Sections are drawn from a non-empty value of one buffer to a non-empty value of another indicator buffer. To specify what value should be considered as "empty", set this value in the [PLOT_EMPTY_VALUE](#) property:

```
//--- The 0 (empty) value will not participate in drawing
PlotIndexSetDouble(index_of_plot_DRAW_ZIGZAG, PLOT_EMPTY_VALUE, 0);
```

Always explicitly fill in the values of the indicator buffers, set an empty value in a buffer to skip bars.

The number of buffers required for plotting DRAW_ZIGZAG is 2.

An example of the indicator that plots a saw based on the High and Low prices. The color, width and style of the zigzag lines change randomly every N ticks.

Note that initially for `plot1` with DRAW_ZIGZAG the properties are set using the compiler directive [#property](#), and then in the [OnCalculate\(\)](#) function these properties are set randomly. The N parameter is set in [external parameters](#) of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

```

Comment(comm);
}
```

DRAW_FILLING

The DRAW_FILLING style plots a colored area between the values of two indicator buffers. In fact, this style draws two lines and fills the space between them with one of two specified colors. It is used for creating indicators that draw channels. None of the buffers can contain only empty values, since in this case nothing is plotted.

You can set two fill colors:

- the first color is used for the areas where values in the first buffer are greater than the values in the second indicator buffer;
- the second color is used for the areas where values in the second buffer are greater than the values in the first indicator buffer.

The fill color can be set using the [compiler directives](#) or dynamically using the [PlotIndexSetInteger\(\)](#) function. Dynamic changes of the plotting properties allows "to enliven" indicators, so that their appearance changes depending on the current situation.

The indicator is calculated for all bars, for which the values of the both indicator buffers are equal neither to 0 nor to the empty value. To specify what value should be considered as "empty", set this value in [PLOT_EMPTY_VALUE](#) property:

```
#define INDICATOR_EMPTY_VALUE -1.0
...
//--- INDICATOR_EMPTY_VALUE (empty value) will not participate in calculation of
PlotIndexSetDouble (DRAW_FILLING_creation_index,PLOT_EMPTY_VALUE,INDICATOR_EMPTY_V
```

Drawing on the bars that do not participate in the indicator calculation will depend on the values in the indicator buffers:

- Bars, for which the values of both indicator buffers are equal to 0, do not participate in drawing the indicator. It means that the area with zero values is not filled out.

- Bars, for which the values of the indicator buffers are equal to the "empty value", participate in drawing the indicator. The area with empty values will be filled out so that to connect the areas with significant values.

It should be noted that if the "empty value" is equal to zero, the bars that do not participate in the indicator calculation are also filled out.

The number of buffers required for plotting DRAW_FILLING is 2.

An example of the indicator that draws a channel between two MAs with different averaging periods in a separate window. The change of the colors at the crossing of moving averages visually shows the change of the upward and downward trends. The colors change randomly every N ticks. The N parameter is set in [external parameters](#) of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

Note that initially for `plot1` with `DRAW_FILLING` the properties are set using the compiler directive `#property`, and then in the `OnCalculate()` function new colors are set randomly.

```

DRAW_BARS

The DRAW_BARS style draws bars on the values of four indicator buffers, which contain the Open, High, Low and Close prices. It is used for creating custom indicators as bars, including those in a separate subwindow of a chart and on other financial instruments.

The color of bars can be set using the [compiler directives](#) or dynamically using the [PlotIndexSetInteger\(\)](#) function. Dynamic changes of the plotting properties allows "to enliven" indicators, so that their appearance changes depending on the current situation.

The indicator is drawn only to those bars, for which non-empty values of **all** four indicator buffers are set. To specify what value should be considered as "empty", set this value in the [PLOT_EMPTY_VALUE](#) property:

```
//--- The 0 (empty) value will not participate in drawing
PlotIndexSetDouble(index_of_plot_DRAW_BARS,PLOT_EMPTY_VALUE,0);
```

Always explicitly fill in the values of the indicator buffers, set an empty value in a buffer to skip bars.

The number of required buffers for plotting DRAW_BARS is 4. All buffers for the plotting should go one after the other in the given order: Open, High, Low and Close. None of the buffers can contain only empty values, since in this case nothing is plotted.

An example of the indicator that draws bars on a selected financial instrument in a separate window. The color of bars changes randomly every N ticks. The N parameter is set in [external parameters](#) of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

Please note that for `plot1` with the DRAW_BARS style, the color is set using the compiler directive [#property](#), and then in the [OnCalculate\(\)](#) function the color is set randomly from an earlier prepared list.

DRAW_CANDLES

The DRAW_CANDLES style draws candlesticks on the values of four indicator buffers, which contain the Open, High, Low and Close prices. It is used for creating custom indicators as a sequence of candlesticks, including those in a separate subwindow of a chart and on other financial instruments.

The color of candlesticks can be set using the [compiler directives](#) or dynamically using the [PlotIndexSetInteger\(\)](#) function. Dynamic changes of the plotting properties allows "to enliven" indicators, so that their appearance changes depending on the current situation.

The indicator is drawn only to those bars, for which non-empty values of all four indicator buffers are set. To specify what value should be considered as "empty", set this value in the [PLOT_EMPTY_VALUE](#) property:

```
//--- The 0 (empty) value will not participate in drawing
PlotIndexSetDouble(index_of_plot_DRAW_CANDLES,PLOT_EMPTY_VALUE,0);
```

Always explicitly fill in the values of the indicator buffers, set an empty value in a buffer to skip bars.

The number of required buffers for plotting DRAW_CANDLES is 4. All buffers for the plotting should go one after the other in the given order: Open, High, Low and Close. None of the buffers can contain only empty values, since in this case nothing is plotted.

You can set up to three colors for the DRAW_CANDLES style affecting the candle look. If only one color is set, it is applied to all candles on a chart.

```
//--- identical candles with a single color applied to them
#property indicator_label1 "One color candles"
#property indicator_type1 DRAW_CANDLES
//--- only one color is specified, therefore all candles are of the same color
#property indicator_color1 clrGreen
```

If two comma-separated colors are specified, the first one is applied to candle outlines, while the second one is applied to the body.

```
//--- different colors for candles and wicks
#property indicator_label1 "Two color candles"
#property indicator_type1 DRAW_CANDLES
//--- green is applied to wicks and outlines, while white is applied to the body
#property indicator_color1 clrGreen,clrWhite
```

Specify three comma-separated colors so that rising and falling candles are displayed differently. In that case, the first color is applied to the candle outlines, while the second and third ones - to bullish and bearish candles.

```
//--- different colors for candles and wicks
#property indicator_label1 "One color candles"
#property indicator_type1 DRAW_CANDLES
//--- wicks and outlines are green, bullish candle body is white, while bearish candle
#property indicator_color1 clrGreen,clrWhite,clrRed
```

Thus, the DRAW_CANDLES style allows you to create custom candle coloring options. Besides, all colors can be changed dynamically during the indicator operation using the PlotIndexSetInteger function

(composition_index_DRAW_CANDLES, PLOT_LINE_COLOR, modifier_index, color), where modifier_index may have the following values:

- 0 - colors of outlines and wicks
- 1- bullish candle body color
- 2 - bearish candle body color

```
//--- set the color of outlines and wicks
PlotIndexSetInteger(0,PLOT_LINE_COLOR,0,clrBlue);
//--- set the bullish body color
PlotIndexSetInteger(0,PLOT_LINE_COLOR,1,clrGreen);
//--- set the bearish body color
PlotIndexSetInteger(0,PLOT_LINE_COLOR,2,clrRed);
```

An example of the indicator that draws candlesticks for a selected financial instrument in a separate window. The color of candlesticks changes randomly every N ticks. The N parameter is set in [external parameters](#) of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

Please note that for plot1, the color is set using the compiler directive [#property](#), and then in the [OnCalculate\(\)](#) function the color is set randomly from an earlier prepared list.

```

DRAW_COLOR_LINE

The DRAW_COLOR_LINE value is a colored variant of the [DRAW_LINE](#) style; it also draws a line using the values of the indicator buffer. But this style, like all color styles with the word **COLOR** in their title has an additional special indicator buffer that stores the color index (number) from a specially set array of colors. Thus, the color of each line segment can be defined by specifying the color index of the index to draw the line at this bar.

The width, style and colors of lines can be set using the [compiler directives](#) and dynamically using the [PlotIndexSetInteger\(\)](#) function. Dynamic changes of the plotting properties allows "to enliven" indicators, so that their appearance changes depending on the current situation.

The number of buffers required for plotting DRAW_COLOR_LINE is 2.

- one buffer to store the indicator values used for drawing a line;
- one buffer to store the index of the color of the line on each bar.

Colors can be specified by the compiler directive `#property indicator_color1` separated by a comma. The number of colors cannot exceed 64.

```
//--- Define 5 colors for coloring each bar (they are stored in the special array)
#property indicator_color1 clrRed,clrBlue,clrGreen,clrOrange,clrDeepPink // (Up to 64)
```

An example of the indicator that draws a line using Close prices of bars. The line width and style change randomly every N=5 ticks.

The colors of the line segments also change randomly in the custom function ChangeColors().

```
//+-----+
//| Changes the color of line segments |
//+-----+
void ChangeColors(color &cols[],int plot_colors)
```

```

{
//--- The number of colors
    int size=ArraySize(cols);
//---
    string comm=ChartGetString(0,CHART_COMMENT)+"\r\n\r\n";

//--- For each color index define a new color randomly
    for(int plot_color_ind=0;plot_color_ind<plot_colors;plot_color_ind++)
    {
        //--- Get a random value
        int number=MathRand();

//---
}

```

The example shows the feature of the "color" versions of indicators - to change the color of a line segment, you do not need to change values in the ColorLineColors[] buffer (which contains the color indexes). All you need to do is set new colors in a special array. This allows you to quickly change the color once for the entire plotting, changing only a small array of colors using the [PlotIndexSetInteger\(\)](#) function.

Note that initially for plot1 with DRAW_COLOR_LINE the properties are set using the compiler directive [#property](#), and then in the [OnCalculate\(\)](#) function these three properties are set randomly.

The N and Length (the length of color segments in bars) parameters are set in [external parameters](#) of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

DRAW_COLOR_SECTION

The DRAW_COLOR_SECTION style is a color version of [DRAW_SECTION](#), but unlike the latter, it allows drawing sections of different colors. The DRAW_COLOR_SECTION style, like all color styles with the word **COLOR** in their title, contains an additional special indicator buffer that stores the color index (number) from a specially set array of colors. Thus, the color of each section can be defined by specifying the color index of the index of the bar that corresponds to the section end.

The width, color and style of the sections can be specified like for the [DRAW_SECTION](#) style - using [compiler directives](#) or dynamically using the [PlotIndexSetInteger\(\)](#) function. Dynamic changes of the plotting properties allows "to enliven" indicators, so that their appearance changes depending on the current situation.

Sections are drawn from one non-empty value to another non-empty value of the indicator buffer, empty values are ignored. To specify what value should be considered as "empty", set this value in the [PLOT_EMPTY_VALUE](#) property: For example, if the indicator should be drawn as a sequence of sections on non-zero values, then you need to set the zero value as an empty one:

```
//--- The 0 (empty) value will not participate in drawing  
PlotIndexSetDouble(index_of_plot_DRAW_COLOR_SECTION, PLOT_EMPTY_VALUE, 0);
```

Always explicitly fill in the values of the indicator buffers, set an empty value in a buffer to the elements that should not be plotted.

The number of buffers required for plotting DRAW_COLOR_SECTION is 2.

- one buffer to store the indicator values used for drawing a line;
- one buffer to store the color index, which is used to draw the section (it makes sense to set only non-empty values).

Colors can be specified by the compiler directive [#property indicator_color1](#) separated by a comma. The number of colors cannot exceed 64.

An example of the indicator that draws colored sections each 5 bars long, using the High price values. The color, width and style of sections change randomly every N ticks.

Note that initially for `plot1` with `DRAW_COLOR_SECTION` 8 colors are set using the compiler directive `#property`. Then in the `OnCalculate()` function, colors are set randomly from the array of colors `colors[]`.

The `N` parameter is set in [external parameters](#) of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

DRAW_COLOR_HISTOGRAM

The DRAW_COLOR_HISTOGRAM style draws a histogram as a sequence of colored columns from zero to a specified value. Values are taken from the indicator buffer. Each column can have its own color from a predefined set of colors.

The width, color and style of the histogram can be specified like for the [DRAW_HISTOGRAM](#) style - using [compiler directives](#) or dynamically using the [PlotIndexSetInteger\(\)](#) function. Dynamic changes of the plotting properties allows changing the look of the histogram based on the current situation.

Since a column from the zero level is drawn on each bar, DRAW_COLOR_HISTOGRAM should better be used in a separate chart window. Most often this type of plotting is used to create indicators of the oscillator type, for example, [Awesome Oscillator](#) or [Market Facilitation Index](#). For the empty non-displayable values the zero value should be specified.

The number of buffers required for plotting DRAW_COLOR_HISTOGRAM is 2.

- one buffer for storing a non-zero value of the vertical segment on each bar, the second end of the segment is always on the zero line of the indicator;
- one buffer to store the color index, which is used to draw the section (it makes sense to set only non-empty values).

Colors can be specified using the compiler directive `#property indicator_color1` separated by a comma. The number of colors cannot exceed 64.

An example of the indicator that draws a sinusoid of a specified color based on the [MathSin\(\)](#) function. The color, width and style of all histogram columns change randomly each N ticks. The bars parameter specifies the period of the sinusoid, that is after the specified number of bars the sinusoid will repeat the cycle.

Please note that for `plot1` with the DRAW_COLOR_HISTOGRAM style, 5 colors are set using the compiler directive `#property`, and then in the [OnCalculate\(\)](#) function the colors are selected randomly

from the 14 colors stored in the colors[] array. The N parameter is set in [external parameters](#) of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

DRAW_COLOR_HISTOGRAM2

The DRAW_COLOR_HISTOGRAM2 style draws a histogram of a specified color - vertical segments using the values of two indicator buffers. But unlike the one-color DRAW_HISTOGRAM2, in this style each column of the histogram can have its own color from a predefined set. The values of all the segments are taken from the indicator buffer.

The width, style and color of the histogram can be specified like for the [DRAW_HISTOGRAM2](#) style - using [compiler directives](#) or dynamically using the [PlotIndexSetInteger\(\)](#) function. Dynamic changes of the plotting properties allows changing the look of the histogram based on the current situation.

The DRAW_COLOR_HISTOGRAM2 style can be used in a separate subwindow of a chart and in its main window. For empty values nothing is drawn, all the values in the indicator buffers need to be set explicitly. Buffers are not initialized with empty values.

The number of buffers required for plotting DRAW_COLOR_HISTOGRAM2 is 3:

- two buffers to store the upper and lower end of the vertical segment on each bar;
- one buffer to store the color index, which is used to draw the segment (it makes sense to set only non-empty values).

An example of the indicator that draws a histogram of a specified color between the High and Low prices. For each day of week, the histogram lines have a different color. The color of the day, width and style of the histogram change randomly each N ticks.

Please note that for `plot1` with the DRAW_COLOR_HISTOGRAM2 style, 5 colors are set using the compiler directive `#property`, and then in the [OnCalculate\(\)](#) function the colors are selected randomly from the 14 colors stored in the `colors[]` array.

The N parameter is set in [external parameters](#) of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

DRAW_COLOR_ARROW

The DRAW_COLOR_ARROW style draws colored arrows (symbols of the set [Wingdings](#)) based on the value of the indicator buffer. In contrast to DRAW_ARROW, in this style it is possible to set a color from a predefined set of colors specified by the [indicator_color1](#) property for each symbol.

The width and color of the symbols can be specified like for the [DRAW_ARROW](#) style - using [compiler directives](#) or dynamically using the [PlotIndexSetInteger\(\)](#) function. Dynamic changes of the plotting properties allows changing the look of an indicator based on the current situation.

The symbol code is set using the [PLOT_ARROW](#) property.

```
//--- Define the symbol code from the Wingdings font to draw in PLOT_ARROW  
PlotIndexSetInteger(0,PLOT_ARROW,code);
```

The default value of PLOT_ARROW=159 (a circle).

Each arrow is actually a symbol that has the height and the anchor point, and can cover some important information on a chart (for example, the closing price at the bar). Therefore, we can additionally specify the vertical shift in pixels, which does not depend on the scale of the chart. The arrows will be shifted down by the specified number of pixels, although the values of the indicator will remain the same:

```
//--- Set the vertical shift of arrows in pixels  
PlotIndexSetInteger(0,PLOT_ARROW_SHIFT,shift);
```

A negative value of PLOT_ARROW_SHIFT means the shift of arrows upwards, a positive values shifts the arrow down.

The DRAW_COLOR_ARROW style can be used in a separate subwindow of a chart and in its main window. Empty values are not drawn and do not appear in the "Data Window", all the values in the indicator buffers should be set explicitly. Buffers are not initialized with a zero value.

```
//--- Set an empty value  
PlotIndexSetDouble(DRAW_COLOR_ARROW_plot_index,PLOT_EMPTY_VALUE,0);
```

The number of buffers required for plotting DRAW_COLOR_ARROW is 2.

- a buffer to store the value of the price which is used to draw the symbol (plus a shift in pixels, given in the PLOT_ARROW_SHIFT property);
- a buffer to store the color index, which is used to draw an arrow (it makes sense to set only non-empty values).

An example of the indicator, which draws arrows on each bar with the close price higher than the close price of the previous bar. The width, shift and symbol code of **all** arrows are changed randomly every N ticks. The color of the symbol depends on the number of the bar on which it is drawn.

In the example, for `plot1` with the `DRAW_COLOR_ARROW` style, the properties, color and size are specified using the compiler directive `#property`, and then in the `OnCalculate()` function the properties are set randomly. The `N` parameter is set in [external parameters](#) of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

Please note that initially 8 colors are set using the compiler directive `#property`, and then in the `OnCalculate()` function, the color is set randomly from the 14 colors that are stored in the `colors[]` array.

DRAW_COLOR_ZIGZAG

The DRAW_COLOR_ZIGZAG style draws segments of different colors, using the values of two indicator buffers. This style is a colored version of [DRAW_ZIGZAG](#), i.e. allows specifying for each segment an individual color from the predefined set of colors. The segments are plotted from a value in the first buffer to a value in the second indicator buffer. None of the buffers can contain only empty values, since in this case nothing is plotted.

The width, color and style of the line can be specified like for the [DRAW_ZIGZAG](#) style - using [compiler directives](#) or dynamically using the [PlotIndexSetInteger\(\)](#) function. Dynamic changes of the plotting properties allows "to enliven" indicators, so that their appearance changes depending on the current situation.

Sections are drawn from a non-empty value of one buffer to a non-empty value of another indicator buffer. To specify what value should be considered as "empty", set this value in the [PLOT_EMPTY_VALUE](#) property:

```
//--- The 0 (empty) value will not participate in drawing
PlotIndexSetDouble(index_of_plot_DRAW_COLOR_ZIGZAG, PLOT_EMPTY_VALUE, 0);
```

Always explicitly fill in the of the indicator buffers, set an empty value in a buffer to skip bars.

The number of buffers required for plotting DRAW_COLOR_ZIGZAG is 3:

- two buffers to store the values of ends of the zigzag sections;
- one buffer to store the color index, which is used to draw the section (it makes sense to set only non-empty values).

An example of the indicator that plots a saw based on the High and Low prices. The color, width and style of the zigzag lines change randomly every N ticks.

Please note that for `plot1` with the `DRAW_COLOR_ZIGZAG` style, 8 colors are set using the compiler directive `#property`, and then in the `OnCalculate()` function the color is selected randomly from the 14 colors stored in the `colors[]` array.

The `N` parameter is set in [external parameters](#) of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

DRAW_COLOR_BARS

The DRAW_COLOR_BARS style draws bars on the values of four indicator buffers, which contain the Open, High, Low and Close prices. This style is an advanced version of [DRAW_BARS](#) and allows specifying for each bar an individual color from the predefined set of colors. It used for creating custom indicators as bars, including those in a separate subwindow of a chart and on other financial instruments.

The color of bars can be set using the [compiler directives](#) or dynamically using the [PlotIndexSetInteger\(\)](#) function. Dynamic changes of the plotting properties allows "to enliven" indicators, so that their appearance changes depending on the current situation.

The indicator is drawn only to those bars, for which non-empty values of all four indicator buffers are set. To specify what value should be considered as "empty", set this value in the [PLOT_EMPTY_VALUE](#) property:

```
//--- The 0 (empty) value will not participate in drawing  
PlotIndexSetDouble(index_of_plot_DRAW_COLOR_BARS,PLOT_EMPTY_VALUE,0);
```

Always explicitly fill in the values of the indicator buffers, set an empty value in a buffer to skip bars.

The number of buffers required for plotting DRAW_COLOR_BARS is 5:

- four buffer to store the values of Open, High, Low and Close;
- one buffer to store the color index, which is used to draw a bar (it makes sense to set it only for the bars that will be drawn).

All buffers for the plotting should go one after the other in the given order: Open, High, Low, Close and the color buffer. None of the price buffers can contain only null values, since in this case nothing is plotted.

An example of the indicator that draws bars on a selected financial instrument in a separate window. The color of bars changes randomly every N ticks. The N parameter is set in [external parameters](#) of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

Please note that for `plot1` with the `DRAW_COLOR_BARS` style, 8 colors are set using the compiler directive `#property`, and then in the `OnCalculate()` function the color is selected randomly from the 14 colors stored in the `colors[]` array.

DRAW_COLOR_CANDLES

The DRAW_COLOR_CANDLES style, like [DRAW_CANDLES](#), draws candlesticks using the values of four indicator buffers, which contain Open, High, Low and Close prices. In addition, it allows specifying a color for each candlestick from a given set. For this purpose, the style has a special color buffer that stores color indexes for each bar. It used for creating custom indicators as a sequence of candlesticks, including those in a separate subwindow of a chart and on other financial instruments.

The number of colors of candlesticks can be set using the [compiler directives](#) or dynamically using the [PlotIndexSetInteger\(\)](#) function. Dynamic changes of the plotting properties allows "to enliven" indicators, so that their appearance changes depending on the current situation.

The indicator is drawn only to those bars, for which non-empty values of four price buffers of the indicator are set. To specify what value should be considered as "empty", set this value in the [PLOT_EMPTY_VALUE](#) property:

```
//--- The 0 (empty) value will not participate in drawing  
PlotIndexSetDouble(index_of_plot_DRAW_COLOR_CANDLES, PLOT_EMPTY_VALUE, 0);
```

Always explicitly fill in the values of the indicator buffers, set an empty value in a buffer to skip bars.

The number of required buffers for plotting DRAW_COLOR_CANDLES is 5:

- four buffer to store the values of Open, High, Low and Close;
- one buffer to store the color index, which is used to draw a candlestick (it makes sense to set it only for the candlesticks that will be drawn).

All buffers for the plotting should go one after the other in the given order: Open, High, Low, Close and the color buffer. None of the price buffers can contain only empty values, since in this case nothing is plotted.

An example of the indicator that draws candlesticks for a selected financial instrument in a separate window. The color of candlesticks changes randomly every N ticks. The N parameter is set in [external parameters](#) of the indicator for the possibility of manual configuration (the Parameters tab in the indicator's Properties window).

Please note that for `plot1`, the color is set using the compiler directive `#property`, and then in the `OnCalculate()` function the color is set randomly from an earlier prepared list.

```

Connection between Indicator Properties and Corresponding Functions

Every custom indicator has numerous [properties](#), some of which are obligatory and are always positioned at the beginning of description. They are the following properties:

- indication of a window to plot the indicator - `indicator_separate_window` or `indicator_chart_window`;
- number of indicator buffers - `indicator_buffers`;
- number of plots of the indicator - `indicator_plots`.

Also there are other properties that can be set both through [preprocessor](#) directives and through functions intended for custom indicator creation. These properties and corresponding functions are described in the following table.

Directives for properties of indicator subwindow	Functions of IndicatorSet... () type	Description of the adjusted property of the subwindow
<code>indicator_height</code>	IndicatorSetInteger (INDICATOR_INDICATOR_HEIGHT , nHeight)	The fixed value of the subwindow height
<code>indicator_minimum</code>	IndicatorSetDouble (INDICATOR_MINIMUM , dMaxValue)	Minimal value of the vertical axis
<code>indicator_maximum</code>	IndicatorSetDouble (INDICATOR_MAXIMUM , dMinValue)	Maximal value of the vertical axis
<code>indicator_levelN</code>	IndicatorSetDouble (INDICATOR_LEVELVALUE , N-1, nLevelValue)	Vertical axis value for N level
no preprocessor directive	IndicatorSetString (INDICATOR_LEVELTEXT , N-1, sLevelName)	Name of a displayed level
<code>indicator_levelcolor</code>	IndicatorSetInteger (INDICATOR_LEVELCOLOR , N-1, nLevelColor)	Color of N level
<code>indicator_levelwidth</code>	IndicatorSetInteger (INDICATOR_LEVELWIDTH , N-1, nLevelWidth)	Line width for N level
<code>indicator_levelstyle</code>	IndicatorSetInteger (INDICATOR_LEVELSTYLE , N-1, nLevelStyle)	Line style for N level
Directives for plotting properties	Functions of PlotIndexSet... () type	Description of the adjusted property of a plot
<code>indicator_labelN</code>	PlotIndexSetString (N-1, PLOT_LABEL ,sLabel)	Short name of the number N plot. It is displayed in

		DataWindow and in the pop-up tooltip when pointing the mouse cursor over it
indicator_colorN	PlotIndexSetInteger (N-1, PLOT_LINE_COLOR , nColor)	Line color for N plot
indicator_styleN	PlotIndexSetInteger (N-1, PLOT_LINE_STYLE , nType)	Line style for N plot
indicator_typeN	PlotIndexSetInteger (N-1, PLOT_DRAW_TYPE , nType)	Line type for N plot
indicator_widthN	PlotIndexSetInteger (N-1, PLOT_LINE_WIDTH , nWidth)	Line width for N plot
Common indicator properties	Functions of IndicatorSet... () type	Description
no preprocessor directive	IndicatorSetString (INDICATOR_SHORTNAME , sShortName)	Sets the convenient short name of the indicator that will be displayed in the list of indicators (opened in the terminal by pressing Ctrl+I).
no preprocessor directive	IndicatorSetInteger (INDICATOR_DIGITS , nDigits)	Sets required accuracy of display of indicator values - number of decimal places
no preprocessor directive	IndicatorSetInteger (INDICATOR_LEVELS , nLevels)	Sets number of levels in the indicator window
indicator_applied_price	No function, the property can be set only by the preprocessor directive.	Default price type used for the indicator calculation. It is specified when necessary, only if OnCalculate() of the first type is used. The property value can also be set from the dialog of indicator properties in the "Parameters" tab - "Apply to" .

It should be noted that numeration of levels and plots in preprocessor terms starts with one, while numeration of the same properties at using functions starts with zero, i.e. the indicated value must be by 1 less than that indicated for #property.

There are several directives, for which there are no corresponding functions:

Directive	Description
indicator_chart_window	Indicator is displayed in the main window
indicator_separate_window	Indicator is displayed in a separate subwindow
indicator_buffers	Number of required indicator buffers

indicator_plots

Number of [plots](#) in the indicator

SetIndexBuffer

The function binds a specified indicator buffer with one-dimensional dynamic array of the [double](#) type.

```
bool SetIndexBuffer(
    int          index,          // buffer index
    double       buffer[],       // array
    ENUM_INDEXBUFFER_TYPE data_type // what will be stored
);
```

Parameters

index

[in] Number of the indicator buffer. The numbering starts with 0. The number must be less than the value declared in [#property indicator_buffers](#).

buffer[]

[in] An array declared in the custom indicator program.

data_type

[in] Type of data stored in the indicator array. By default it is [INDICATOR_DATA](#) (values of the calculated indicator). It may also take the value of [INDICATOR_COLOR_INDEX](#); in this case this buffer is used for storing color indexes for the previous indicator buffer. You can specify up to 64 [colors](#) in the [#property indicator_colorN](#) line. The [INDICATOR_CALCULATIONS](#) value means that the buffer is used in intermediate calculations of the indicator and is not intended for drawing.

Return Value

If successful, returns [true](#), otherwise - [false](#).

Note

After binding, the dynamic array `buffer[]` will be indexed as in common arrays, even if the indexing of [timeseries](#) is pre-installed for the bound array. If you want to change the order of access to elements of the indicator array, use the [ArraySetAsSeries\(\)](#) function **after binding the array using the `SetIndexBuffer()` function**. Please note that you can't change the size for dynamic arrays set as indicator buffers by the function [SetIndexBuffer\(\)](#). For indicator buffers, all operations of size changes are performed by the executing sub-system of the terminal.

Example:

[Custom Indicator Properties](#), [Access to timeseries and indicators](#)

IndicatorSetDouble

The function sets the value of the corresponding indicator property. Indicator property must be of the double type. There are two variants of the function.

Call with specifying the property identifier.

```
bool IndicatorSetDouble(
    int    prop_id,           // identifier
    double prop_value        // value to be set
);
```

Call with specifying the property identifier and modifier.

```
bool IndicatorSetDouble(
    int    prop_id,           // identifier
    int    prop_modifier,    // modifier
    double prop_value        // value to be set
)
```

Parameters

prop_id

[in] Identifier of the indicator property. The value can be one of the values of the [ENUM_CUSTOMIND_PROPERTY_DOUBLE](#) enumeration.

prop_modifier

[in] Modifier of the specified property. Only level properties require a modifier. Numbering of levels starts from 0. It means that in order to set property for the second level you need to specify 1 (1 less than when using [compiler directive](#)).

prop_value

[in] Value of property.

Return Value

In case of successful execution, returns true, otherwise - false.

Note

Numbering of properties (modifiers) starts from 1 (one) when using the #property directive, while the function uses numbering from 0 (zero). In case the level number is set incorrectly, [indicator display](#) can differ from the intended one.

For example, the first level value for the indicator in a separate subwindow can be set in two ways:

- property indicator_level1 50 - the value of 1 is used for specifying the level number,
- IndicatorSetDouble(INDICATOR_LEVELVALUE, 0, 50) - 0 is used for specifying the first level.

Example: indicator that turns upside down the maximum and minimum values of the indicator window and values of levels on which the horizontal lines are placed.

```
#property indicator_separate_window
//--- set the maximum and minimum values for the indicator window
#property indicator_minimum 0
#property indicator_maximum 100
//--- display three horizontal levels in a separate indicator window
#property indicator_level1 25
#property indicator_level2 50
#property indicator_level3 75
//--- set thickness of horizontal levels
#property indicator_levelwidth 1
//--- set style of horizontal levels
#property indicator_levelstyle STYLE_DOT
//+-----+
//| Custom indicator initialization function |
//+-----+
int OnInit()
{
//--- set descriptions of horizontal levels
IndicatorSetString(INDICATOR_LEVELTEXT,0,"First Level (index 0)");
IndicatorSetString(INDICATOR_LEVELTEXT,1,"Second Level (index 1)");
IndicatorSetString(INDICATOR_LEVELTEXT,2,"Third Level (index 2)");
//--- set the short name for indicator
IndicatorSetString(INDICATOR_SHORTNAME,"IndicatorSetDouble() Demo");
//--- set color for each level
IndicatorSetInteger(INDICATOR_LEVELCOLOR,0,clrBlue);
IndicatorSetInteger(INDICATOR_LEVELCOLOR,1,clrGreen);
IndicatorSetInteger(INDICATOR_LEVELCOLOR,2,clrRed);
```

```

//---
    return(INIT_SUCCEEDED);
}
//+-----+
//| Custom indicator iteration function |
//+-----+

int OnCalculate(const int rates_total,
               const int prev_calculated,
               const datetime &time[],
               const double &open[],
               const double &high[],
               const double &low[],
               const double &close[],
               const long &tick_volume[],
               const long &volume[],
               const int &spread[])
{
    static int tick_counter=0;
    static double level1=25,level2=50,level3=75;
    static double max=100,min=0, shift=100;
//--- calculate ticks
    tick_counter++;
//--- turn levels upside down on every 10th tick
    if(tick_counter%10==0)
    {
        //--- invert sign for the level values
        level1=-level1;
        level2=-level2;
        level3=-level3;
        //--- invert sign for the maximum and minimum values
        max-=shift;
        min-=shift;
        //--- invert the shift value
        shift=-shift;
        //--- set new level values
        IndicatorSetDouble(INDICATOR_LEVELVALUE,0,level1);
        IndicatorSetDouble(INDICATOR_LEVELVALUE,1,level2);
        IndicatorSetDouble(INDICATOR_LEVELVALUE,2,level3);
        //--- set new values of maximum and minimum in the indicator window
        Print("Set up max = ",max," min = ",min);
        IndicatorSetDouble(INDICATOR_MAXIMUM,max);
        IndicatorSetDouble(INDICATOR_MINIMUM,min);
    }
//--- return value of prev_calculated for next call
    return(rates_total);
}

```

[Indicator Styles in Examples](#), [Connection between Indicator Properties and Functions](#), [Drawing Styles](#)

IndicatorSetInteger

The function sets the value of the corresponding indicator property. Indicator property must be of the int or color type. There are two variants of the function.

Call with specifying the property identifier.

```
bool IndicatorSetInteger (
    int prop_id,           // identifier
    int prop_value         // value to be set
);
```

Call with specifying the property identifier and modifier.

```
bool IndicatorSetInteger (
    int prop_id,           // identifier
    int prop_modifier,     // modifier
    int prop_value         // value to be set
);
```

Parameters

prop_id

[in] Identifier of the indicator property. The value can be one of the values of the [ENUM_CUSTOMIND_PROPERTY_INTEGER](#) enumeration.

prop_modifier

[in] Modifier of the specified property. Only level properties require a modifier.

prop_value

[in] Value of property.

Return Value

In case of successful execution, returns true, otherwise - false.

Note

Numbering of properties (modifiers) starts from 1 (one) when using the #property directive, while the function uses numbering from 0 (zero). In case the level number is set incorrectly, [indicator display](#) can differ from the intended one.

For example, in order to set thickness of the first horizontal line use zeroth index:

- `IndicatorSetInteger(INDICATOR_LEVELWIDTH, 0, 5)` - index 0 is used to set thickness of the first level.

Example: indicator that sets color, style and thickness of the indicator horizontal lines.

```
#property indicator_separate_window
#property indicator_minimum 0
#property indicator_maximum 100
//--- display three horizontal levels in a separate indicator window
#property indicator_level1 20
#property indicator_level2 50
#property indicator_level3 80
//--- set thickness of horizontal levels
#property indicator_levelwidth 5
//--- set color of horizontal levels
#property indicator_levelcolor clrAliceBlue
//--- set style of horizontal levels
#property indicator_levelstyle STYLE_DOT
//+-----+
//| Custom indicator initialization function |
//+-----+
int OnInit()
{
//--- set descriptions of horizontal levels
IndicatorSetString(INDICATOR_LEVELTEXT,0,"First Level (index 0)");
IndicatorSetString(INDICATOR_LEVELTEXT,1,"Second Level (index 1)");
IndicatorSetString(INDICATOR_LEVELTEXT,2,"Third Level (index 2)");
//--- set the short name for indicator
IndicatorSetString(INDICATOR_SHORTNAME,"IndicatorSetInteger() Demo");
return(INIT_SUCCEEDED);
}
//+-----+
```

```

//| Custom indicator iteration function |
//+-----+
int OnCalculate(const int rates_total,
               const int prev_calculated,
               const datetime &time[],
               const double &open[],
               const double &high[],
               const double &low[],
               const double &close[],
               const long &tick_volume[],
               const long &volume[],
               const int &spread[])
{
    static int tick_counter=0;

[Custom Indicator Properties](#), [Program Properties \(#property\)](#), [Drawing Styles](#)

IndicatorSetString

The function sets the value of the corresponding indicator property. Indicator property must be of the string type. There are two variants of the function.

Call with specifying the property identifier.

```
bool IndicatorSetString(
    int     prop_id,           // identifier
    string  prop_value        // value to be set
);
```

Call with specifying the property identifier and modifier.

```
bool IndicatorSetString(
    int     prop_id,           // identifier
    int     prop_modifier,    // modifier
    string  prop_value        // value to be set
)
```

Parameters

prop_id

[in] Identifier of the indicator property. The value can be one of the values of the [ENUM_CUSTOMIND_PROPERTY_STRING](#) enumeration.

prop_modifier

[in] Modifier of the specified property. Only level properties require a modifier.

prop_value

[in] Value of property.

Return Value

In case of successful execution, returns true, otherwise - false.

Note

Numbering of properties (modifiers) starts from 1 (one) when using the #property directive, while the function uses numbering from 0 (zero). In case the level number is set incorrectly, [indicator display](#) can differ from the intended one.

For example, in order to set description of the first horizontal line use zeroth index:

- IndicatorSetString(INDICATOR_LEVELTEXT, 0, "First Level") - index 0 is used to set text description of the first level.

Example: indicator that sets text labels to the indicator horizontal lines.

```
#property indicator_separate_window
#property indicator_minimum 0
#property indicator_maximum 100
//--- display three horizontal levels in a separate indicator window
#property indicator_level1 30
#property indicator_level2 50
#property indicator_level3 70
//--- set color of horizontal levels
#property indicator_levelcolor clrRed
//--- set style of horizontal levels
#property indicator_levelstyle STYLE_SOLID
//+-----+
//| Custom indicator initialization function |
//+-----+
int OnInit()
{
//--- set descriptions of horizontal levels
IndicatorSetString(INDICATOR_LEVELTEXT,0,"First Level (index 0)");
IndicatorSetString(INDICATOR_LEVELTEXT,1,"Second Level (index 1)");
IndicatorSetString(INDICATOR_LEVELTEXT,2,"Third Level (index 2)");
//--- set the short name for indicator
IndicatorSetString(INDICATOR_SHORTNAME,"IndicatorSetString() Demo");
//---
return(INIT_SUCCEEDED);
}
//+-----+
//| Custom indicator iteration function |
```

```
//+-----+
int OnCalculate(const int rates_total,
               const int prev_calculated,
               const datetime &time[],
               const double &open[],
               const double &high[],
               const double &low[],
               const double &close[],
               const long &tick_volume[],
               const long &volume[],
               const int &spread[])
{
//---

//--- return value of prev_calculated for next call
    return(rates_total);
}
```

See also

[Custom Indicator Properties](#), [Program Properties \(#property\)](#)

PlotIndexSetDouble

The function sets the value of the corresponding property of the corresponding indicator line. The indicator property must be of the double type.

```
bool PlotIndexSetDouble(  
    int     plot_index,    // plotting style index  
    int     prop_id,       // property identifier  
    double  prop_value     // value to be set  
);
```

Parameters

plot_index

[in] Index of the [graphical plotting](#)

prop_id

[in] The value can be one of the values of the [ENUM_PLOT_PROPERTY_DOUBLE](#) enumeration.

prop_value

[in] The value of the property.

Return Value

If successful, returns [true](#), otherwise [false](#).

PlotIndexSetInteger

The function sets the value of the corresponding property of the corresponding indicator line. The indicator property must be of the int, char, bool or color type. There are 2 variants of the function.

Call indicating identifier of the property.

```
bool PlotIndexSetInteger (
    int  plot_index,      // plotting style index
    int  prop_id,         // property identifier
    int  prop_value       // value to be set
);
```

Call indicating the identifier and modifier of the property.

```
bool PlotIndexSetInteger (
    int  plot_index,      // plotting style index
    int  prop_id,         // property identifier
    int  prop_modifier,   // property modifier
    int  prop_value       // value to be set
)
```

Parameters

plot_index

[in] Index of the [graphical plotting](#)

prop_id

[in] The value can be one of the values of the [ENUM_PLOT_PROPERTY_INTEGER](#) enumeration.

prop_modifier

[in] Modifier of the specified property. Only color index properties require a modifier.

prop_value

[in] The value of the property.

Return Value

If successful, returns [true](#), otherwise [false](#).

Example: an indicator that draws a three-color line. The color scheme changes every 5 ticks.

```
#property indicator_chart_window
#property indicator_buffers 2
#property indicator_plots 1
//---- plot ColorLine
#property indicator_label1 "ColorLine"
#property indicator_type1 DRAW_COLOR_LINE
#property indicator_color1 clrRed,clrGreen,clrBlue
#property indicator_style1 STYLE_SOLID
#property indicator_width1 3
//--- indicator buffers
double ColorLineBuffer[];
double ColorBuffer[];
int MA_handle;
//+-----+
//| Custom indicator initialization function |
//+-----+
void OnInit()
{
//--- indicator buffers mapping
SetIndexBuffer(0,ColorLineBuffer,INDICATOR_DATA);
SetIndexBuffer(1,ColorBuffer,INDICATOR_COLOR_INDEX);
//--- get MA handle
MA_handle=iMA(Symbol(),0,10,0,MODE_EMA,PRICE_CLOSE);
//---
}
//+-----+
//| get color index |
//+-----+
```

```

int getIndexOfColor(int i)
{
    int j=i%300;
    if(j<100) return(0); // first index
    if(j<200) return(1); // second index
    return(2); // third index
}

//+-----+
//| Custom indicator iteration function |
//+-----+

int OnCalculate(const int rates_total,
               const int prev_calculated,
               const datetime &time[],
               const double &open[],
               const double &high[],
               const double &low[],
               const double &close[],
               const long &tick_volume[],
               const long &volume[],
               const int &spread[])
{
    //---
    static int ticks=0,modified=0;
    int limit;
    //--- first calculation or number of bars was changed
    if(prev_calculated==0)
    {
        //--- copy values of MA into indicator buffer ColorLineBuffer
        int copied=CopyBuffer(MA_handle,0,0,rates_total,ColorLineBuffer);
        if(copied<=0) return(0); // copying failed - throw away
        //--- now set line color for every bar
        for(int i=0;i<rates_total;i++)
            ColorBuffer[i]=getIndexOfColor(i);
    }
    else

        if(copied<=0) return(0);

        ticks++; // ticks counting
        if(ticks>=5) // it's time to change color scheme
        {
            ticks=0; // reset counter
            modified++; // counter of color changes
            if(modified>=3) modified=0; // reset counter
            ResetLastError();
            switch(modified)
            {

```

```

    case 0:// first color scheme
        PlotIndexSetInteger(0,PLOT_LINE_COLOR,0,clrRed);
        PlotIndexSetInteger(0,PLOT_LINE_COLOR,1,clrBlue);
        PlotIndexSetInteger(0,PLOT_LINE_COLOR,2,clrGreen);
        Print("Color scheme "+modified);
        break;
    case 1:// second color scheme
        PlotIndexSetInteger(0,PLOT_LINE_COLOR,0,clrYellow);
        PlotIndexSetInteger(0,PLOT_LINE_COLOR,1,clrPink);
        PlotIndexSetInteger(0,PLOT_LINE_COLOR,2,clrLightSlateGray);
        Print("Color scheme "+modified);
        break;
    default:// third color scheme
        PlotIndexSetInteger(0,PLOT_LINE_COLOR,0,clrLightGoldenrod);
        PlotIndexSetInteger(0,PLOT_LINE_COLOR,1,clrOrchid);
        PlotIndexSetInteger(0,PLOT_LINE_COLOR,2,clrLimeGreen);
        Print("Color scheme "+modified);
    }
}
else
{
    //--- set start position
    limit=prev_calculated-1;
    //--- now we set line color for every bar
    for(int i=limit;i<rates_total;i++)
        ColorBuffer[i]=getIndexOfColor(i);
}

//--- return value of prev_calculated for next call
return(rates_total);
}
//+-----+

```

PlotIndexSetString

The function sets the value of the corresponding property of the corresponding indicator line. The indicator property must be of the string type.

```
bool PlotIndexSetString(  
    int    plot_index,    // plotting style index  
    int    prop_id,       // property identifier  
    string prop_value     // value to be set  
);
```

Parameters

plot_index

[in] Index of [graphical plot](#)

prop_id

[in] The value can be one of the values of the [ENUM_PLOT_PROPERTY_STRING](#) enumeration.

prop_value

[in] The value of the property.

Return Value

If successful, returns [true](#), otherwise [false](#).

PlotIndexGetInteger

The function sets the value of the corresponding property of the corresponding indicator line. The indicator property must be of the int, color, bool or char type. There are 2 variants of the function.

Call indicating identifier of the property.

```
int PlotIndexGetInteger (
    int plot_index,      // plotting style index
    int prop_id,         // property identifier
);
```

Call indicating the identifier and modifier of the property.

```
int PlotIndexGetInteger (
    int plot_index,      // plotting index
    int prop_id,         // property identifier
    int prop_modifier    // property modifier
)
```

Parameters

plot_index

[in] Index of the [graphical plotting](#)

prop_id

[in] The value can be one of the values of the [ENUM_PLOT_PROPERTY_INTEGER](#) enumeration.

prop_modifier

[in] Modifier of the specified property. Only color index properties require a modifier.

Note

Function is designed to extract the settings of drawing of the appropriate indicator line. The function works in tandem with the function [PlotIndexSetInteger](#) to copy the drawing properties of one line to another.

Example: an indicator that colors candles depending on the day of the week. Colors for each day are set in a programmatically.

```
#property indicator_separate_window
#property indicator_buffers 5
#property indicator_plots 1
//---- plot ColorCandles
#property indicator_label1 "ColorCandles"
#property indicator_type1 DRAW_COLOR_CANDLES
#property indicator_style1 STYLE_SOLID
#property indicator_width1 1
//--- indicator buffers
double      OpenBuffer[];
double      HighBuffer[];
double      LowBuffer[];
double      CloseBuffer[];
double      ColorCandlesColors[];
color       ColorOfDay[6]={CLR_NONE,clrMediumSlateBlue,
                           clrDarkGoldenrod,clrForestGreen,clrBlueViolet,clrRed};

//+-----+
//| Custom indicator initialization function |
//+-----+
void OnInit()
{
//--- indicator buffers mapping
SetIndexBuffer(0,OpenBuffer,INDICATOR_DATA);
SetIndexBuffer(1,HighBuffer,INDICATOR_DATA);
SetIndexBuffer(2,LowBuffer,INDICATOR_DATA);
SetIndexBuffer(3,CloseBuffer,INDICATOR_DATA);
SetIndexBuffer(4,ColorCandlesColors,INDICATOR_COLOR_INDEX);
//--- set number of colors in color buffer
```

```

    PlotIndexSetInteger(0,PLOT_COLOR_INDEXES,6);
//--- set colors for color buffer
    for(int i=1;i<6;i++)
        PlotIndexSetInteger(0,PLOT_LINE_COLOR,i,ColorOfDay[i]);
//--- set accuracy
    IndicatorSetInteger(INDICATOR_DIGITS,_Digits);
    printf("We have %u colors of days",PlotIndexGetInteger(0,PLOT_COLOR_INDEXES));
//---
    }
//+-----+
//| Custom indicator iteration function |
//+-----+

        //--- set color for every candle
        TimeToStruct(time[i],t);
        ColorCandlesColors[i]=t.day_of_week;
        //---
        i++;
    }
//--- return value of prev_calculated for next call
    return(rates_total);
}
//+-----+

```

Object Functions

This is the group of functions intended for working with graphic objects relating to any specified chart.

The functions defining the properties of graphical objects, as well as [ObjectCreate\(\)](#) and [ObjectMove\(\)](#) operations for creating and moving objects along the chart are actually used for sending commands to the chart. If these functions are executed successfully, the command is included in the common queue of the chart events. Visual changes in the properties of graphical objects are implemented when handling the queue of the chart events.

Thus, do not expect an immediate visual update of graphical objects after calling these functions. Generally, the graphical objects on the chart are updated automatically by the terminal following the change events - a new quote arrival, resizing the chart window, etc. Use [ChartRedraw\(\)](#) function to forcefully update the graphical objects.

Function	Action
ObjectCreate	Creates an object of the specified type in a specified chart
ObjectName	Returns the name of an object of the corresponding type in the specified chart (specified chart subwindow)
ObjectDelete	Removes the object with the specified name from the specified chart (from the specified chart subwindow)
ObjectsDeleteAll	Removes all objects of the specified type from the specified chart (from the specified chart subwindow)
ObjectFind	Searches for an object with the specified ID by the name
ObjectGetTimeByValue	Returns the time value for the specified object price value
ObjectGetValueByTime	Returns the price value of an object for the specified time
ObjectMove	Changes the coordinates of the specified object anchor point
ObjectsTotal	Returns the number of objects of the specified type in the specified chart (specified chart subwindow)
ObjectGetDouble	Returns the double value of the corresponding object property
ObjectGetInteger	Returns the integer value of the corresponding object property

<u>ObjectGetString</u>	Returns the string value of the corresponding object property
<u>ObjectSetDouble</u>	Sets the value of the corresponding object property
<u>ObjectSetInteger</u>	Sets the value of the corresponding object property
<u>ObjectSetString</u>	Sets the value of the corresponding object property
<u>TextSetFont</u>	Sets the font for displaying the text using drawing methods (Arial 20 used by default)
<u>TextOut</u>	Transfers the text to the custom array (buffer) designed for creation of a graphical <u>resource</u>
<u>TextGetSize</u>	Returns the string's width and height at the current <u>font settings</u>

Every graphical object should have a name unique within one [chart](#), including its subwindows. Changing of a name of a graphic object generates two events: event of deletion of an object with the old name, and event of creation of an object with a new name.

After an object is created or an [object property](#) is modified it is recommended to call the [ChartRedraw\(\)](#) function, which commands the client terminal to forcibly draw a chart (and all [visible](#) objects in it).

ObjectCreate

The function creates an object with the specified name, type, and the initial coordinates in the specified chart subwindow. During creation up to 30 coordinates can be specified.

```
bool  ObjectCreate(
    long      chart_id,      // chart identifier
    string     name,         // object name
    ENUM_OBJECT type,        // object type
    sub_window nwin,         // window index
    datetime   time1,        // time of the first anchor point
    double     price1,       // price of the first anchor point
    ...
    datetime   timeN=0,      // time of the N-th anchor point
    double     priceN=0,     // price of the N-th anchor point
    ...
    datetime   time30=0,     // time of the 30th anchor point
    double     price30=0     // price of the 30th anchor point
);
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] Name of the object. The name must be unique within a chart, including its subwindows.

type

[in] Object type. The value can be one of the values of the [ENUM_OBJECT](#) enumeration.

sub_window

[in] Number of the chart subwindow. 0 means the main chart window. The specified subwindow must exist, otherwise the function returns false.

time1

[in] The time coordinate of the first anchor.

price1

[in] The price coordinate of the first anchor point.

timeN=0

[in] The time coordinate of the N-th anchor point.

priceN=0

[in] The price coordinate of the N-th anchor point.

time30=0

[in] The time coordinate of the thirtieth anchor point.

price30=0

[in] The price coordinate of the thirtieth anchor point.

Return Value

Returns true or false depending on whether the object is created or not. To read more about the [error](#) call [GetLastError\(\)](#). If the object has been created already, the function tries to change its coordinates.

Note

An object name should not exceed 63 characters.

The numbering of the chart subwindows (if there are subwindows with indicators in the chart) starts with 1. The main chart window of the chart is and always has index 0.

The large number of anchor points (up to 30) is implemented for future use. At the same time, the limit of 30 possible anchor points for graphical objects is determined by the limit on the number of parameters (not more than 64) that can be used when calling a function.

When an object is renamed, two events are formed simultaneously. These events can be handled in an Expert Advisor or indicator by the [OnChartEvent\(\)](#) function:

- an event of deletion of an object with the old name;
- an event of creation of an object with a new name.

There is a certain number of anchor points that must be specified when creating each [object type](#):

ID	Description	Anchor Points
OBJ_VLINE	Vertical Line	One anchor point. Actually only the time coordinate is used.
OBJ_HLINE	Horizontal Line	One anchor point. Actually only the price coordinate is used.
OBJ_TREND	Trend Line	Two anchor points.
OBJ_TRENDBYANGLE	Trend Line By Angle	Two anchor points.
OBJ_CYCLES	Cycle Lines	Two anchor points.
OBJ_ARROWED_LINE	Arrowed Line	Two anchor points.
OBJ_CHANNEL	Equidistant Channel	Three anchor points.
OBJ_STDDEVCHANNEL	Standard Deviation Channel	Two anchor points.
OBJ_REGRESSION	Linear Regression Channel	Two anchor points.
OBJ_PITCHFORK	Andrews' Pitchfork	Three anchor points.
OBJ_GANNLINE	Gann Line	Two anchor points.
OBJ_GANNFAN	Gann Fan	Two anchor points.
OBJ_GANNGRID	Gann Grid	Two anchor points.
OBJ_FIBO	Fibonacci Retracement	Two anchor points.
OBJ_FIBOTIMES	Fibonacci Time Zones	Two anchor points.
OBJ_FIBOFAN	Fibonacci Fan	Two anchor points.

<u>OBJ_FIBOARC</u>	Fibonacci Arcs	Two anchor points.
<u>OBJ_FIBOCHANNEL</u>	Fibonacci Channel	Three anchor points.
<u>OBJ_EXPANSION</u>	Fibonacci Expansion	Three anchor points.
<u>OBJ_ELLIOTWAVE5</u>	Elliott Motive Wave	Five anchor points.
<u>OBJ_ELLIOTWAVE3</u>	Elliott Correction Wave	Three anchor points.
<u>OBJ_RECTANGLE</u>	Rectangle	Two anchor points.
<u>OBJ_TRIANGLE</u>	Triangle	Three anchor points.
<u>OBJ_ELLIPSE</u>	Ellipse	Three anchor points.
<u>OBJ_ARROW_THUMB_UP</u>	Thumbs Up	One anchor point.
<u>OBJ_ARROW_THUMB_DOWN</u>	Thumbs Down	One anchor point.
<u>OBJ_ARROW_UP</u>	Arrow Up	One anchor point.
<u>OBJ_ARROW_DOWN</u>	Arrow Down	One anchor point.
<u>OBJ_ARROW_STOP</u>	Stop Sign	One anchor point.
<u>OBJ_ARROW_CHECK</u>	Check Sign	One anchor point.
<u>OBJ_ARROW_LEFT_PRICE</u>	Left Price Label	One anchor point.
<u>OBJ_ARROW_RIGHT_PRICE</u>	Right Price Label	One anchor point.
<u>OBJ_ARROW_BUY</u>	Buy Sign	One anchor point.
<u>OBJ_ARROW_SELL</u>	Sell Sign	One anchor point.
<u>OBJ_ARROW</u>	Arrow	One anchor point.
<u>OBJ_TEXT</u>	Text	One anchor point.
<u>OBJ_LABEL</u>	Label	Position is set using the <u>OBJPROP_XDISTANCE</u> and <u>OBJPROP_YDISTANCE</u> properties.
<u>OBJ_BUTTON</u>	Button	Position is set using the <u>OBJPROP_XDISTANCE</u> and <u>OBJPROP_YDISTANCE</u> properties.
<u>OBJ_CHART</u>	Chart	Position is set using the <u>OBJPROP_XDISTANCE</u> and <u>OBJPROP_YDISTANCE</u> properties.
<u>OBJ_BITMAP</u>	Bitmap	One anchor point.
<u>OBJ_BITMAP_LABEL</u>	Bitmap Label	Position is set using the <u>OBJPROP_XDISTANCE</u> and

		<u>OBJPROP_YDISTANCE</u> properties.
<u>OBJ_EDIT</u>	Edit	Position is set using the <u>OBJPROP_XDISTANCE</u> and <u>OBJPROP_YDISTANCE</u> properties.
<u>OBJ_EVENT</u>	The "Event" object corresponding to an event in the economic calendar	One anchor point. Actually only the time coordinate is used.
<u>OBJ_RECTANGLE_LABEL</u>	The "Rectangle label" object for creating and designing the custom graphical interface.	Position is set using the <u>OBJPROP_XDISTANCE</u> and <u>OBJPROP_YDISTANCE</u> properties.

ObjectName

The function returns the name of the corresponding object in the specified chart, in the specified subwindow, of the specified type.

```
string ObjectName(  
    long  chart_id,           // chart identifier  
    int   pos,               // number in the list of objects  
    int   sub_window=-1,     // window index  
    int   type=-1            // object type  
);
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

pos

[in] Ordinal number of the object according to the specified filter by the number and type of the subwindow.

sub_window=-1

[in] Number of the chart subwindow. 0 means the main chart window, -1 means all the subwindows of the chart, including the main window.

type=-1

[in] Type of the object. The value can be one of the values of the [ENUM_OBJECT](#) enumeration. -1 means all types.

Return Value

Name of the object is returned in case of success.

Note

When an object is renamed, two events are formed simultaneously. These events can be handled in an Expert Advisor or indicator by the [OnChartEvent\(\)](#) function:

- an event of deletion of an object with the old name;
- an event of creation of an object with a new name.

ObjectDelete

The function removes the object with the specified name from the specified chart.

```
bool ObjectDelete(  
    long    chart_id,    // chart identifier  
    string  name         // object name  
);
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] Name of object to be deleted.

Return Value

Returns true if the removal was successful, otherwise returns false. To read more about the [error](#) call [GetLastError\(\)](#).

Note

When an object is renamed, two events are formed simultaneously. These events can be handled in an Expert Advisor or indicator by the [OnChartEvent\(\)](#) function:

- an event of deletion of an object with the old name;
- an event of creation of an object with a new name.

ObjectsDeleteAll

Removes all objects from the specified chart, specified chart subwindow, of the specified type.

```
int ObjectsDeleteAll(  
    long   chart_id,           // chart identifier  
    int    sub_window=-1,     // window index  
    int    type=-1            // object type  
);
```

Removes all objects of the specified type using prefix in object names.

```
int ObjectsDeleteAll(  
    long      chart_id,       // chart ID  
    const string prefix,     // prefix in object name  
    int       sub_window=-1,  // window index  
    int       object_type=-1  // object type  
);
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

prefix

[in] Prefix in object names. All objects whose names start with this set of characters will be removed from chart. You can specify prefix as 'name' or 'name*' - both variants will work the same. If an empty string is specified as the prefix, objects with all possible names will be removed.

sub_window=-1

[in] Number of the chart subwindow. 0 means the main chart window, -1 means all the subwindows of the chart, including the main window.

type=-1

[in] Type of the object. The value can be one of the values of the [ENUM_OBJECT](#) enumeration. -1 means all types.

Return Value

Returns the number of deleted objects. To read more about the [error](#) call [GetLastError\(\)](#).

ObjectFind

The function searches for an object with the specified name in the chart with the specified ID.

```
int ObjectFind(  
    long    chart_id,    // chart identifier  
    string  name         // object name  
);
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] The name of the searched object.

Return Value

If successful the function returns the number of the subwindow (0 means the main window of the chart), in which the object is found. If the object is not found, the function returns a negative number. To read more about the [error](#) call [GetLastError\(\)](#).

Note

When an object is renamed, two events are formed simultaneously. These events can be handled in an Expert Advisor or indicator by the [OnChartEvent\(\)](#) function:

- an event of deletion of an object with the old name;
- an event of creation of an object with a new name.

ObjectGetTimeByValue

The function returns the time value for the specified price value of the specified object.

```
datetime ObjectGetTimeByValue(  
    long    chart_id,      // chart identifier  
    string  name,          // object name  
    double  value,         // Price  
    int     line_id        // Line number  
);
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] Name of the object.

value

[in] Price value.

line_id

[in] Line identifier.

Return Value

The time value for the specified price value of the specified object.

Note

An object can have several values in one price coordinate, therefore it is necessary to specify the line number. This function applies only to the following objects:

- Trendline (OBJ_TREND)
- Trendline by angle (OBJ_TRENDBYANGLE)
- Gann line (OBJ_GANNLIN)
- Equidistant channel (OBJ_CHANNEL) - 2 lines
- Linear regression channel (OBJ_REGRESSION) - 3 lines
- Standard deviation channel (OBJ_STDDEVCHANNEL) - 3 lines
- Arrowed line (OBJ_ARROWED_LINE)

[Object Types](#)

ObjectGetValueByTime

The function returns the price value for the specified time value of the specified object.

```
double ObjectGetValueByTime(  
    long      chart_id,      // chart identifier  
    string     name,         // object name  
    datetime  time,         // Time  
    int       line_id        // Line number  
);
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] Name of the object.

time

[in] Time value.

line_id

[in] Line ID.

Return Value

The price value for the specified time value of the specified object.

Note

An object can have several values in one price coordinate, therefore it is necessary to specify the line number. This function applies only to the following objects:

- Trendline (OBJ_TREND)
- Trendline by angle (OBJ_TRENDBYANGLE)
- Gann line (OBJ_GANNLIN)
- Equidistant channel (OBJ_CHANNEL) - 2 lines
- Linear regression channel (OBJ_REGRESSION) - 3 lines
- Standard deviation channel (OBJ_STDDEVCHANNEL) - 3 lines
- Arrowed line (OBJ_ARROWED_LINE)

[Object Types](#)

ObjectMove

The function changes coordinates of the specified anchor point of the object.

```
bool ObjectMove(  
    long      chart_id,      // chart identifier  
    string     name,         // object name  
    int        point_index,   // anchor point number  
    datetime   time,         // Time  
    double     price         // Price  
);
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] Name of the object.

point_index

[in] Index of the anchor point. The number of anchor points depends on the type of object.

time

[in] Time coordinate of the selected anchor point.

price

[in] Price coordinate of the selected anchor point.

Return Value

If successful, returns true, in case of failure returns false. To read more about the [error](#) call [GetLastError\(\)](#).

ObjectsTotal

The function returns the number of objects in the specified chart, specified subwindow, of the specified type.

```
int ObjectsTotal(  
    long  chart_id,           // chart identifier  
    int   sub_window=-1,     // window index  
    int   type=-1            // object type  
);
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

sub_window=-1

[in] Number of the chart subwindow. 0 means the main chart window, -1 means all the subwindows of the chart, including the main window.

type=-1

[in] Type of the object. The value can be one of the values of the [ENUM_OBJECT](#) enumeration. -1 means all types.

Return Value

The number of objects.

ObjectSetDouble

The function sets the value of the corresponding object property. The object property must be of the [double](#) type. There are 2 variants of the function.

Setting property value, without modifier

```
bool ObjectSetDouble(
    long          chart_id,      // chart identifier
    string        name,          // object name
    ENUM_OBJECT_PROPERTY_DOUBLE prop_id, // property
    double        prop_value     // value
);
```

Setting a property value indicating the modifier

```
bool ObjectSetDouble(
    long          chart_id,      // chart identifier
    string        name,          // object name
    ENUM_OBJECT_PROPERTY_DOUBLE prop_id, // property
    int          prop_modifier, // modifier
    double        prop_value     // value
);
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] Name of the object.

prop_id

[in] ID of the object property. The value can be one of the values of the [ENUM_OBJECT_PROPERTY_DOUBLE](#) enumeration.

prop_modifier

[in] Modifier of the specified property. It denotes the number of the level in [Fibonacci tools](#) and in the graphical object Andrew's pitchfork. The numeration of levels starts from zero.

prop_value

[in] The value of the property.

Return Value

The function returns true only if the command to change properties of a graphical object has been sent to a chart successfully. Otherwise it returns false. To read more about the [error](#) call [GetLastError\(\)](#).

Example of creating a Fibonacci object and adding a new level in it

```
///| Script program start function |
//+-----+
//+-----+
```

```

void OnStart()
{
//--- auxiliary arrays
double high[],low[],price1,price2;
datetime time[],time1,time2;
//--- Copy the open prices - 100 latest bars are enough
int copied=CopyHigh(Symbol(),0,0,100,high);
if(copied<=0)
{
    Print("Failed to copy the values of the High price series");
    return;
}
//--- Copy the close price - 100 latest bars are enough
copied=CopyLow(Symbol(),0,0,100,low);
if(copied<=0)
{
    Print("Failed to copy the values of the Low price series");
    return;
}
//--- Copy the open time for the last 100 bars
copied=CopyTime(Symbol(),0,0,100,time);
if(copied<=0)
{
    Print("Failed to copy the values of the price series of Time");
    return;
}
//--- Organize access to the copied data as to timeseries - backwards
ArraySetAsSeries(high,true);
ArraySetAsSeries(low,true);
ArraySetAsSeries(time,true);

//--- Coordinates of the first anchor point of the Fibo object
price1=high[70];
time1=time[70];
//--- Coordinates of the second anchor point of the Fibo object
price2=low[50];
time2=time[50];

//--- Time to create the Fibo object
bool created=ObjectCreate(0,"Fibo",OBJ_FIBO,0,time1,price1,time2,price2);
if(created) // If the object is created successfully
{
    //--- set the color of Fibo levels
    ObjectSetInteger(0,"Fibo",OBJPROP_LEVELCOLOR,Blue);
    //--- by the way, how much Fibo levels do we have?
    int levels=ObjectGetInteger(0,"Fibo",OBJPROP_LEVELS);
    Print("Fibo levels before = ",levels);
    //---output to the Journal => number of level:value level_description
    for(int i=0;i<levels;i++)

```

```

    {
        Print(i,": ",ObjectGetDouble(0,"Fibo",OBJPROP_LEVELVALUE,i),
              " ",ObjectGetString(0,"Fibo",OBJPROP_LEVELTEXT,i));
    }
    //--- Try to increase the number of levels per unit
    bool modified=ObjectSetInteger(0,"Fibo",OBJPROP_LEVELS,levels+1);
    if(!modified) // failed to change the number of levels
    {
        Print("Failed to change the number of levels of Fibo, error ",GetLastError())
    }
    //--- just inform
    Print("Fibo levels after = ",ObjectGetInteger(0,"Fibo",OBJPROP_LEVELS));
    //--- set a value for a newly created level
    bool added=ObjectSetDouble(0,"Fibo",OBJPROP_LEVELVALUE,levels,133);
    if(added) // managed to set a value for the level
    {
        Print("Successfully set one more Fibo level");
        //--- Also do not forget to set the level description
        ObjectSetString(0,"Fibo",OBJPROP_LEVELTEXT,levels,"my level");
        ChartRedraw(0);
        //--- Get the actual value of the number of levels in the Fibo object
        levels=ObjectGetInteger(0,"Fibo",OBJPROP_LEVELS);
        Print("Fibo levels after adding = ",levels);
        //--- once again output all levels - just to make sure
        for(int i=0;i<levels;i++)
        {
            Print(i,":",ObjectGetDouble(0,"Fibo",OBJPROP_LEVELVALUE,i),
                  " ",ObjectGetString(0,"Fibo",OBJPROP_LEVELTEXT,i));
        }
    }
    else // Fails if you try to increase the number of levels in the Fibo object
    {
        Print("Failed to set one more Fibo level. Error ",GetLastError());
    }
}
}

```

[Object Types](#), [Object Properties](#)

ObjectSetInteger

The function sets the value of the corresponding object property. The object property must be of the [datetime](#), [int](#), [color](#), [bool](#) or [char](#) type. There are 2 variants of the function.

Setting property value, without modifier

```
bool ObjectSetInteger(
    long          chart_id,      // chart identifier
    string        name,         // object name
    ENUM_OBJECT_PROPERTY_INTEGER prop_id, // property
    long          prop_value    // value
);
```

Setting a property value indicating the modifier

```
bool ObjectSetInteger(
    long          chart_id,      // chart identifier
    string        name,         // object name
    ENUM_OBJECT_PROPERTY_INTEGER prop_id, // property
    int           prop_modifier, // modifier
    long          prop_value    // value
);
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] Name of the object.

prop_id

[in] ID of the object property. The value can be one of the values of the [ENUM_OBJECT_PROPERTY_INTEGER](#) enumeration.

prop_modifier

[in] Modifier of the specified property. It denotes the number of the level in [Fibonacci tools](#) and in the graphical object Andrew's pitchfork. The numeration of levels starts from zero.

prop_value

[in] The value of the property.

Return Value

The function returns true only if the command to change properties of a graphical object has been sent to a chart successfully. Otherwise it returns false. To read more about the [error](#) call [GetLastError\(\)](#).

[Object Types](#), [Object Properties](#)

ObjectSetString

The function sets the value of the corresponding object property. The object property must be of the [string](#) type. There are 2 variants of the function.

Setting property value, without modifier

```
bool ObjectSetString(
    long          chart_id,      // chart identifier
    string        name,         // object name
    ENUM_OBJECT_PROPERTY_STRING prop_id, // property
    string        prop_value    // value
);
```

Setting a property value indicating the modifier

```
bool ObjectSetString(
    long          chart_id,      // chart identifier
    string        name,         // object name
    ENUM_OBJECT_PROPERTY_STRING prop_id, // property
    int          prop_modifier, // modifier
    string        prop_value    // value
);
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] Name of the object.

prop_id

[in] ID of the object property. The value can be one of the values of the [ENUM_OBJECT_PROPERTY_STRING](#) enumeration.

prop_modifier

[in] Modifier of the specified property. It denotes the number of the level in [Fibonacci tools](#) and in the graphical object Andrew's pitchfork. The numeration of levels starts from zero.

prop_value

[in] The value of the property.

Return Value

The function returns true only if the command to change properties of a graphical object has been sent to a chart successfully. Otherwise it returns false. To read more about the [error](#) call [GetLastError\(\)](#).

Note

When an object is renamed, two events are formed simultaneously. These events can be handled in an Expert Advisor or indicator by the [OnChartEvent\(\)](#) function:

- an event of deletion of an object with the old name;
- an event of creation of an object with a new name.

ObjectGetDouble

The function returns the value of the corresponding object property. The object property must be of the [double](#) type. There are 2 variants of the function.

1. Immediately returns the property value.

```
double ObjectGetDouble(
    long          chart_id,      // chart identifier
    string        name,         // object name
    ENUM_OBJECT_PROPERTY_DOUBLE prop_id, // property identifier
    int          prop_modifier=0 // property modifier, if required
);
```

2. Returns true or false, depending on the success of the function. If successful, the property value is placed to a receiving variable passed by reference by the last parameter.

```
bool ObjectGetDouble(
    long          chart_id,      // chart identifier
    string        name,         // object name
    ENUM_OBJECT_PROPERTY_DOUBLE prop_id, // property identifier
    int          prop_modifier, // property modifier
    double&       double_var    // here we accept the property value
);
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] Name of the object.

prop_id

[in] ID of the object property. The value can be one of the values of the [ENUM_OBJECT_PROPERTY_DOUBLE](#) enumeration.

prop_modifier

[in] Modifier of the specified property. For the first variant, the default modifier value is equal to 0. Most properties do not require a modifier. It denotes the number of the level in [Fibonacci tools](#) and in the graphical object Andrew's pitchfork. The numeration of levels starts from zero.

double_var

[out] Variable of the double type that received the value of the requested property.

Return Value

Value of the double type for the first calling variant.

For the second variant the function returns true, if this property is maintained and the value has been placed into the double_var variable, otherwise returns false. To read more about the [error](#) call [GetLastError\(\)](#).

ObjectGetInteger

The function returns the value of the corresponding object property. The object property must be of the [datetime](#), [int](#), [color](#), [bool](#) or [char](#) type. There are 2 variants of the function.

1. Immediately returns the property value.

```
long ObjectGetInteger(
    long          chart_id,      // chart identifier
    string        name,         // object name
    ENUM_OBJECT_PROPERTY_INTEGER prop_id, // property identifier
    int          prop_modifier=0 // property modifier, if required
);
```

2. Returns true or false, depending on the success of the function. If successful, the property value is placed to a receiving variable passed by reference by the last parameter.

```
bool ObjectGetInteger(
    long          chart_id,      // chart identifier
    string        name,         // object name
    ENUM_OBJECT_PROPERTY_INTEGER prop_id, // property identifier
    int          prop_modifier, // property modifier
    long&         long_var       // here we accept the property value
);
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] Name of the object.

prop_id

[in] ID of the object property. The value can be one of the values of the [ENUM_OBJECT_PROPERTY_INTEGER](#) enumeration.

prop_modifier

[in] Modifier of the specified property. For the first variant, the default modifier value is equal to 0. Most properties do not require a modifier. It denotes the number of the level in [Fibonacci tools](#) and in the graphical object Andrew's pitchfork. The numeration of levels starts from zero.

long_var

[out] Variable of the long type that receives the value of the requested property.

Return Value

The long value for the first calling variant.

For the second variant the function returns true, if this property is maintained and the value has been placed into the long_var variable, otherwise returns false. To read more about the [error](#) call [GetLastError\(\)](#).

ObjectGetString

The function returns the value of the corresponding object property. The object property must be of the [string](#) type. There are 2 variants of the function.

1. Immediately returns the property value.

```
string ObjectGetString(
    long          chart_id,      // chart identifier
    string        name,         // object name
    ENUM_OBJECT_PROPERTY_STRING prop_id, // property identifier
    int          prop_modifier=0 // property modifier, if required
);
```

2. Returns true or false, depending on the success of the function. If successful, the property value is placed to a receiving variable passed by reference by the last parameter.

```
bool ObjectGetString(
    long          chart_id,      // chart identifier
    string        name,         // object name
    ENUM_OBJECT_PROPERTY_STRING prop_id, // property identifier
    int          prop_modifier, // property modifier
    string&       string_var    // here we accept the property value
);
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

name

[in] Name of the object.

prop_id

[in] ID of the object property. The value can be one of the values of the [ENUM_OBJECT_PROPERTY_STRING](#) enumeration.

prop_modifier

[in] Modifier of the specified property. For the first variant, the default modifier value is equal to 0. Most properties do not require a modifier. It denotes the number of the level in [Fibonacci tools](#) and in the graphical object Andrew's pitchfork. The numeration of levels starts from zero.

string_var

[out] Variable of the string type that receives the value of the requested properties.

Return Value

String value for the first version of the call.

For the second version of the call returns true, if this property is maintained and the value has been placed into the *string_var* variable, otherwise returns false. To read more about the [error](#) call [GetLastError\(\)](#).

Note

When an object is renamed, two events are formed simultaneously. These events can be handled in an Expert Advisor or indicator by the [OnChartEvent\(\)](#) function:

- an event of deletion of an object with the old name;
- an event of creation of an object with a new name.

TextSetFont

The function sets the font for displaying the text using drawing methods and returns the result of that operation. Arial font with the size -120 (12 pt) is used by default.

```
bool TextSetFont(  
    const string name,           // font name or path to font file on the disk  
    int size,                   // font size  
    uint flags,                 // combination of flags  
    int orientation=0           // text slope angle  
);
```

Parameters

name

[in] Font name in the system or the name of the resource containing the font or the path to font file on the disk.

size

[in] The font size that can be set using positive and negative values. In case of positive values, the size of a displayed text does not depend on the operating system's font size settings. In case of negative values, the value is set in tenths of a point and the text size depends on the operating system settings ("standard scale" or "large scale"). See the Note below for more information about the differences between the modes.

flags

[in] Combination of [flags](#) describing font style.

orientation

[in] Text's horizontal inclination to X axis, the unit of measurement is 0.1 degrees. It means that *orientation=450* stands for inclination equal to 45 degrees.

Return Value

Returns true if the current font is successfully installed, otherwise false. Possible code errors:

- `ERR_INVALID_PARAMETER(4003)` - *name* presents NULL or "" (empty string),
- `ERR_INTERNAL_ERROR(4001)` - operating system error (for example, an attempt to create a non-existent font).

Note

If ":::" is used in font name, the font is downloaded from [EX5 resource](#). If *name* font name is specified with an extension, the font is downloaded from the file, if the path starts from "\" or "/", the file is searched relative to MQL5 directory. Otherwise, it is searched relative to the path of EX5 file which called `TextSetFont()` function.

The font size is set using positive or negative values. This fact defines the dependence of the text size from the operating system settings (size scale).

- If the size is specified using a positive number, this size is transformed into physical measurement units of a device (pixels) when changing a logical font into a physical one, and this size corresponds to the height of the symbol glyphs picked from the available fonts. This case is not recommended when the texts displayed by [TextOut\(\)](#) function and the ones displayed by [OBJ_LABEL](#) ("Label") graphical object are to be used together on the chart.

- If the size is specified using a negative number, this number is supposed to be set in tenths of a logical point and is divided by 10 (for example, -350 is equal to 35 logical points). An obtained value is then transformed into physical measurement units of a device (pixels) and corresponds to the absolute value of the height of a symbol picked from the available fonts. Multiply the font size specified in the object properties by -10 to make the size of a text on the screen similar to the one in [OBJ_LABEL](#) object.

The flags can be used as the combination of style flags with one of the flags specifying the font width. Flag names are shown below.

Flags for specifying font style

Flag	Description
FONT_ITALIC	Italic
FONT_UNDERLINE	Underline
FONT_STRIKEOUT	Strikeout

Flags for specifying font width

Flag
FW_DONTCARE
FW_THIN
FW_EXTRALIGHT
FW_ULTRALIGHT
FW_LIGHT
FW_NORMAL
FW_REGULAR
FW_MEDIUM
FW_SEMIBOLD
FW_DEMIBOLD
FW_BOLD
FW_EXTRABOLD
FW_ULTRABOLD
FW_HEAVY
FW_BLACK

[Resources](#), [ResourceCreate\(\)](#), [ResourceSave\(\)](#), [TextOut\(\)](#)

TextOut

The function displays a text in a custom array (buffer) and returns the result of that operation. The array is designed to create the graphical [resource](#).

```
bool TextOut(  
    const string      text,           // displayed text  
    int              x,               // X coordinate  
    int              y,               // Y coordinate  
    uint             anchor,          // anchor type  
    uint             &data[],         // output buffer  
    uint             width,           // buffer width in pixels  
    uint             height,          // buffer height in pixels  
    uint             color,           // text color  
    ENUM_COLOR_FORMAT color_format    // color format for output  
);
```

Parameters

text

[in] Displayed text that will be written to the buffer. Only one-lined text is displayed.

x

[in] X coordinate of the anchor point of the displayed text.

y

[in] Y coordinate of the anchor point of the displayed text.

anchor

[in] The value out of the 9 pre-defined methods of the displayed text's anchor point location. The value is set by a combination of two flags - flags of horizontal and vertical text align. Flag names are listed in the Note below.

data[]

[in] Buffer, in which text is displayed. The buffer is used to create the graphical [resource](#).

width

[in] Buffer width in pixels.

height

[in] Buffer height in pixels.

color

[in] Text color.

color_format

[in] Color format is set by [ENUM_COLOR_FORMAT](#) enumeration value.

Return Value

Returns true if successful, otherwise false.

Note

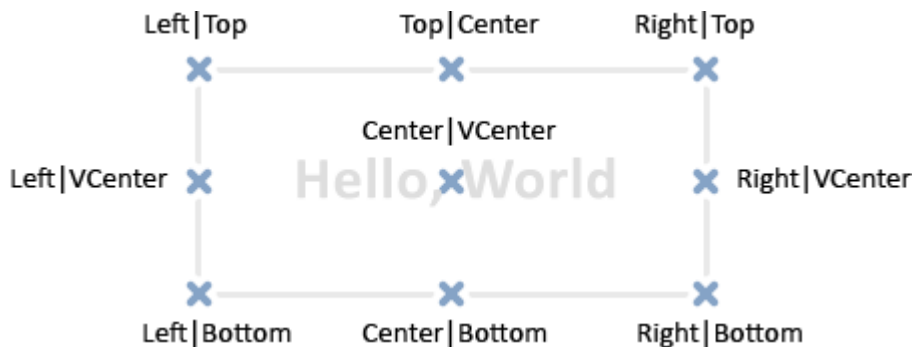

Anchor point specified by *anchor* is a combination of two flags of horizontal and vertical text align.
Horizontal text align flags:

- TA_LEFT - anchor point on the left side of the bounding box
- TA_CENTER - horizontal anchor point is located at the center of the bounding box
- TA_RIGHT - anchor point on the right side of the bounding box

Vertical text align flags:

- TA_TOP - anchor point at the upper side of the bounding box
- TA_VCENTER - vertical anchor point is located at the center of the bounding box
- TA_BOTTOM - anchor point at the lower side of the bounding box

Possible combinations of flags and specified anchor points are shown in the image.

Example:

```
//--- width and height of the canvas (used for drawing)
#define IMG_WIDTH 200
#define IMG_HEIGHT 200
//--- display the parameter window before launching the script
#property script_show_inputs
//--- enable to set color format
input ENUM_COLOR_FORMAT clr_format=COLOR_FORMAT_XRGB_NOALPHA;
//--- drawing array (buffer)
uint ExtImg[IMG_WIDTH*IMG_HEIGHT];
//+-----+
//| Script program start function |
//+-----+
void OnStart()
{
//--- create OBJ_BITMAP_LABEL object for drawing
ObjectCreate(0,"CLOCK",OBJ_BITMAP_LABEL,0,0,0);
//--- specify the name of the graphical resource for writing in CLOCK object
ObjectSetString(0,"CLOCK",OBJPROP_BMPFILE,"::IMG");

//--- auxiliary variables
double a;           // arrow corner
uint nm=2700;       // minute corner
uint nh=2700*12;    // hour counter
uint w,h;           // variables for receiving text string sizes
```

```

    int    x,y;           // variables for calculation of the current coordinates of text

//--- rotate clock hands in an infinite loop, till the script is stopped
while(!IsStopped())
{
    //--- clear the clock drawing buffer array
    ArrayFill(ExtImg,0,IMG_WIDTH*IMG_HEIGHT,0);
    //--- set the font for drawing digits for the clock-face
    TextSetFont("Arial",-200,FW_EXTRABOLD,0);
    //--- draw the clock-face
    for(int i=1;i<=12;i++)
    {
        //--- receive the size of the current hour on the clock-face
        TextGetSize(string(i),w,h);
        //--- calculate the coordinates of the current hour on the clock-face
        a=-((i*300)%3600*M_PI)/1800.0;
        x=IMG_WIDTH/2-int(sin(a)*80+0.5+w/2);
        y=IMG_HEIGHT/2-int(cos(a)*80+0.5+h/2);
        //--- output the hour on the clock-face to ExtImg[] buffer
        TextOut(string(i),x,y,TA_LEFT|TA_TOP,ExtImg,IMG_WIDTH,IMG_HEIGHT,0xFFFFFFFF,clr_1);
    }
    //--- now, specify the font for drawing the minute hand
    TextSetFont("Arial",-200,FW_EXTRABOLD,-int(nm%3600));
    //--- receive the size of the minute hand
    TextGetSize("----->",w,h);
    //--- calculate the coordinates of the minute hand on the clock-face
    a=-(nm%3600*M_PI)/1800.0;
    x=IMG_WIDTH/2-int(sin(a)*h/2+0.5);
    y=IMG_HEIGHT/2-int(cos(a)*h/2+0.5);
    //--- output of the minute hand to the clock-face in ExtImg[]buffer
    TextOut("----->",x,y,TA_LEFT|TA_TOP,ExtImg,IMG_WIDTH,IMG_HEIGHT,0xFFFFFFFF,clr_1);

    //--- now, set the font for drawing the minute hand
    TextSetFont("Arial",-200,FW_EXTRABOLD,-int(nh/12%3600));
    TextGetSize("==>",w,h);
    //--- calculate the coordinates of the hour hand on the clock-face
    a=-(nh/12%3600*M_PI)/1800.0;
    x=IMG_WIDTH/2-int(sin(a)*h/2+0.5);
    y=IMG_HEIGHT/2-int(cos(a)*h/2+0.5);
    //--- output of the hour hand on the clock-face to ExtImg[] buffer
    TextOut("==>",x,y,TA_LEFT|TA_TOP,ExtImg,IMG_WIDTH,IMG_HEIGHT,0xFFFFFFFF,clr_form);

    //--- update the graphical resource
    ResourceCreate("::IMG",ExtImg,IMG_WIDTH,IMG_HEIGHT,0,0,IMG_WIDTH,clr_format);
    //--- forced chart update
    ChartRedraw();

    //--- increase hour and minute counters
    nm+=60;
    nh+=60;
}

```

```
    //--- keeping a short pause between the frames
    Sleep(10);
}
//--- delete CLOCK object when completing the script's operation
ObjectDelete(0,"CLOCK");
//---
}
```

TextGetSize

The function returns the line width and height at the current [font settings](#).

```
bool TextGetSize(  
    const string      text,           // text string  
    uint&             width,          // buffer width in pixels  
    uint&             height         // buffer height in pixels  
);
```

Parameters

text

[in] String, for which length and width should be obtained.

width

[out] Input parameter for receiving width.

height

[out] Input parameter for receiving height.

Return Value

Returns true if successful, otherwise false. Possible code errors:

- `ERR_INTERNAL_ERROR(4001)` - operating system error.

Technical Indicator Functions

All functions like `iMA`, `iAC`, `iMACD`, `ilchimoku` etc. create a copy of the corresponding technical indicator in the global cache of the client terminal. If a copy of the indicator with such parameters already exists, the new copy is not created, and the counter of references to the existing copy increases.

These functions return the handle of the appropriate copy of the indicator. Further, using this handle, you can receive data calculated by the corresponding indicator. The corresponding buffer data (technical indicators contain calculated data in their internal buffers, which can vary from 1 to 5, depending on the indicator) can be copied to a mql5-program using the [CopyBuffer\(\)](#) function.

You can't refer to the indicator data right after it has been created, because calculation of indicator values requires some time, so it's better to create indicator handles in `OnInit()`. Function [iCustom\(\)](#) creates the corresponding custom indicator, and returns its handle in case it is successfully create. Custom indicators can contain up to 512 indicator buffers, the contents of which can also be obtained by the [CopyBuffer\(\)](#) function, using the obtained handle.

There is a universal method for creating any technical indicator using the [IndicatorCreate\(\)](#) function. This function accepts the following data as input parameters:

- symbol name;
- timeframe;
- type of the indicator to create;
- number of input parameters of the indicator;
- an array of [MqlParam](#) type containing all the necessary input parameters.

The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

Note. Repeated call of the indicator function with the same parameters within one mql5-program does not lead to a multiple increase of the reference counter; the counter will be increased only once by 1. However, it's recommended to get the indicators handles in function [OnInit\(\)](#) or in the class constructor, and further use these handles in other functions. The reference counter decreases when a mql5-program is deinitialized.

All indicator functions have at least 2 parameters - symbol and period. The [NULL](#) value of the symbol means the current symbol, the 0 value of the period means the current [timeframe](#).

Function	Returns the handle of the indicator:
iAC	Accelerator Oscillator
iAD	Accumulation/Distribution
iADX	Average Directional Index
iADXWilder	Average Directional Index by Welles Wilder
iAlligator	Alligator
iAMA	Adaptive Moving Average

<u>iAO</u>	Awesome Oscillator
<u>iATR</u>	Average True Range
<u>iBearsPower</u>	Bears Power
<u>iBands</u>	Bollinger Bands®
<u>iBullsPower</u>	Bulls Power
<u>iCCI</u>	Commodity Channel Index
<u>iChaikin</u>	Chaikin Oscillator
<u>iCustom</u>	Custom indicator
<u>iDEMA</u>	Double Exponential Moving Average
<u>iDeMarker</u>	DeMarker
<u>iEnvelopes</u>	Envelopes
<u>iForce</u>	Force Index
<u>iFractals</u>	Fractals
<u>iFrAMA</u>	Fractal Adaptive Moving Average
<u>iGator</u>	Gator Oscillator
<u>ilchimoku</u>	Ichimoku Kinko Hyo
<u>iBWMFI</u>	Market Facilitation Index by Bill Williams
<u>iMomentum</u>	Momentum
<u>iMFI</u>	Money Flow Index
<u>iMA</u>	Moving Average
<u>iOsMA</u>	Moving Average of Oscillator (MACD histogram)
<u>iMACD</u>	Moving Averages Convergence-Divergence
<u>iOBV</u>	On Balance Volume
<u>iSAR</u>	Parabolic Stop And Reverse System
<u>iRSI</u>	Relative Strength Index
<u>iRVI</u>	Relative Vigor Index
<u>iStdDev</u>	Standard Deviation
<u>iStochastic</u>	Stochastic Oscillator
<u>iTEMA</u>	Triple Exponential Moving Average
<u>iTriX</u>	Triple Exponential Moving Averages Oscillator
<u>iWPR</u>	Williams' Percent Range

<u>iVIDyA</u>	Variable Index Dynamic Average
<u>iVolumes</u>	Volumes

iAC

The function creates Accelerator Oscillator in a global cache of the client terminal and returns its handle. It has only one buffer.

```
int iAC(
    string          symbol,      // symbol name
    ENUM_TIMEFRAMES period      // period
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) enumeration values, 0 means the current timeframe.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

iAD

The function returns the handle of the Accumulation/Distribution indicator. It has only one buffer.

```
int iAD(
    string          symbol,          // symbol name
    ENUM_TIMEFRAMES period,          // period
    ENUM_APPLIED_VOLUME applied_volume // volume type for calculation
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) enumeration values, 0 means the current timeframe.

applied_volume

[in] The volume used. Can be any of [ENUM_APPLIED_VOLUME](#) values.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

Example:

```

iADX

The function returns the handle of the Average Directional Movement Index indicator.

```
int iADX(
    string      symbol,          // symbol name
    ENUM_TIMEFRAMES period,      // period
    int         adx_period       // averaging period
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

adx_period

[in] Period to calculate the index.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

Note

The buffer numbers are the following: 0 - MAIN_LINE, 1 - PLUSDI_LINE, 2 - MINUSDI_LINE.

Example:

iADXWilder

The function returns the handle of Average Directional Movement Index by Welles Wilder.

```
int iADXWilder(
    string      symbol,      // symbol name
    ENUM_TIMEFRAMES period,  // period
    int         adx_period   // averaging period
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

adx_period

[in] Period to calculate the index.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

Note

The buffer numbers are the following: 0 - MAIN_LINE, 1 - PLUSDI_LINE, 2 - MINUSDI_LINE.

    //--- clear the chart after deleting the indicator
    Comment("");
}

```

iAlligator

The function returns the handle of the Alligator indicator.

```
int iAlligator(
    string          symbol,          // symbol name
    ENUM_TIMEFRAMES period,          // period
    int             jaw_period,      // period for the calculation of jaws
    int             jaw_shift,       // horizontal shift of jaws
    int             teeth_period,    // period for the calculation of teeth
    int             teeth_shift,     // horizontal shift of teeth
    int             lips_period,     // period for the calculation of lips
    int             lips_shift,      // horizontal shift of lips
    ENUM_MA_METHOD  ma_method,       // type of smoothing
    ENUM_APPLIED_PRICE applied_price // type of price or handle
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

jaw_period

[in] Averaging period for the blue line (Alligator's Jaw)

jaw_shift

[in] The shift of the blue line relative to the price chart.

teeth_period

[in] Averaging period for the red line (Alligator's Teeth).

teeth_shift

[in] The shift of the red line relative to the price chart.

lips_period

[in] Averaging period for the green line (Alligator's lips).

lips_shift

[in] The shift of the green line relative to the price chart.

ma_method

[in] The method of averaging. Can be any of the [ENUM_MA_METHOD](#) values.

applied_price

[in] The price used. Can be any of the price constants [ENUM_APPLIED_PRICE](#) or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

Note

The buffer numbers are the following: 0 - GATORJAW_LINE, 1 - GATORTEETH_LINE, 2 - GATORLIPS_LINE.

iAMA

The function returns the handle of the Adaptive Moving Average indicator. It has only one buffer.

```
int iAMA(
    string          symbol,          // symbol name
    ENUM_TIMEFRAMES period,          // period
    int             ama_period,      // average period for AMA
    int             fast_ma_period,  // fast MA period
    int             slow_ma_period,  // slow MA period
    int             ama_shift,       // horizontal shift of the indicator
    ENUM_APPLIED_PRICE applied_price // type of the price or handle
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

ama_period

[in] The calculation period, on which the efficiency coefficient is calculated.

fast_ma_period

[in] Fast period for the smoothing coefficient calculation for a rapid market.

slow_ma_period

[in] Slow period for the smoothing coefficient calculation in the absence of trend.

ama_shift

[in] Shift of the indicator relative to the price chart.

applied_price

[in] The price used. Can be any of the price constants [ENUM_APPLIED_PRICE](#) or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

}

```

iAO

The function returns the handle of the Awesome Oscillator indicator. It has only one buffer.

```
int iAO(
    string      symbol,      // symbol name
    ENUM_TIMEFRAMES period   // period
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

Example:

```

iATR

The function returns the handle of the Average True Range indicator. It has only one buffer.

```
int iATR(
    string      symbol,      // symbol name
    ENUM_TIMEFRAMES period,  // period
    int         ma_period    // averaging period
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

ma_period

[in] The value of the averaging period for the indicator calculation.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

iBands

The function returns the handle of the Bollinger Bands® indicator.

```
int iBands(
    string          symbol,          // symbol name
    ENUM_TIMEFRAMES period,          // period
    int             bands_period,     // period for average line calculation
    int             bands_shift,      // horizontal shift of the indicator
    double          deviation,        // number of standard deviations
    ENUM_APPLIED_PRICE applied_price // type of price or handle
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

bands_period

[in] The averaging period of the main line of the indicator.

bands_shift

[in] The shift the indicator relative to the price chart.

deviation

[in] Deviation from the main line.

applied_price

[in] The price used. Can be any of the price constants [ENUM_APPLIED_PRICE](#) or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

Note

The buffer numbers are the following: 0 - BASE_LINE, 1 - UPPER_BAND, 2 - LOWER_BAND

Example:

iBullsPower

The function returns the handle of the Bulls Power indicator. It has only one buffer.

```
int iBullsPower(
    string      symbol,           // symbol name
    ENUM_TIMEFRAMES period,       // period
    int         ma_period,        // averaging period
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

ma_period

[in] The averaging period for the indicator calculation.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

iCCI

The function returns the handle of the Commodity Channel Index indicator. It has only one buffer.

```
int iCCI(
    string          symbol,          // symbol name
    ENUM_TIMEFRAMES period,          // period
    int             ma_period,        // averaging period
    ENUM_APPLIED_PRICE applied_price // type of price or handle
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

ma_period

[in] The averaging period for the indicator calculation.

applied_price

[in] The price used. Can be any of the price constants [ENUM_APPLIED_PRICE](#) or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

```

iChaikin

The function returns the handle of the Chaikin Oscillator indicator. It has only one buffer.

```
int iChaikin(
    string          symbol,          // symbol name
    ENUM_TIMEFRAMES period,          // period
    int             fast_ma_period,  // fast period
    int             slow_ma_period,  // slow period
    ENUM_MA_METHOD  ma_method,       // smoothing type
    ENUM_APPLIED_VOLUME applied_volume // type of volume
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

fast_ma_period

[in] Fast averaging period for calculations.

slow_ma_period

[in] Slow averaging period for calculations.

ma_method

[in] Smoothing type. Can be one of the averaging constants of [ENUM_MA_METHOD](#).

applied_volume

[in] The volume used. Can be one of the constants of [ENUM_APPLIED_VOLUME](#).

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

```

iCustom

The function returns the handle of a specified custom indicator.

```
int iCustom(
    string      symbol,      // symbol name
    ENUM_TIMEFRAMES period,  // period
    string      name         // folder/custom_indicator_name
    ...         // list of indicator input parameters
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

name

[in] The name of the custom indicator, with path relative to the root directory of indicators (MQL5/Indicators/). If an indicator is located in a subdirectory, for example, in MQL5/Indicators/Examples, its name must be specified like: "Examples\\indicator_name" (it is necessary to use a double slash instead of the single slash as a separator).

...

[in] [input-parameters](#) of a custom indicator, separated by commas. Type and order of parameters must match. If there is no parameters specified, then [default values](#) will be used.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

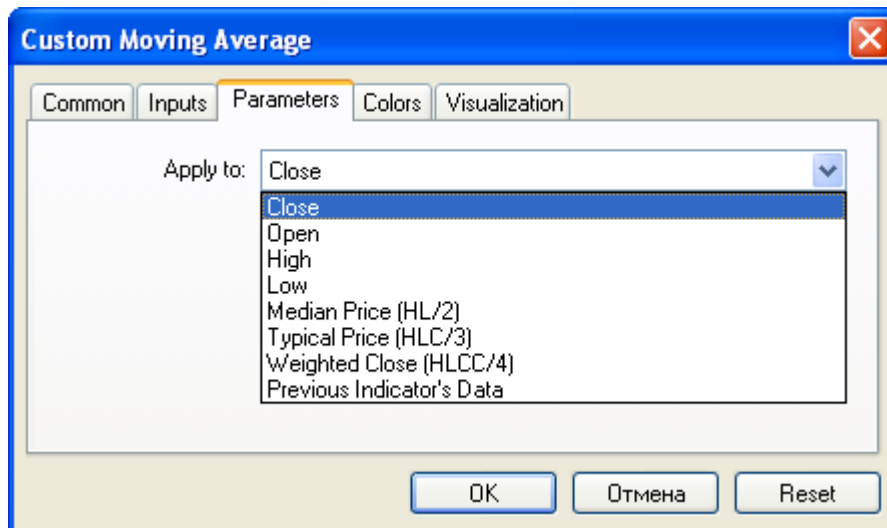

Note

A custom indicator must be compiled (with extension EX5) and located in the directory MQL5/Indicators of the client terminal or its subdirectory.

Indicators that require testing are defined automatically from the call of the iCustom() function, if the corresponding parameter is set through a [constant string](#). For all other cases (use of the [IndicatorCreate\(\)](#) function or use of a non-constant string in the parameter that sets the indicator name) the property [#property tester_indicator](#) is required:

```
#property tester_indicator "indicator_name.ex5"
```

If [the first call form](#) is used in the indicator, then at the custom indicator start you can additionally indicate data for calculation in its "Parameters" tab. If the "Apply to" parameter is not selected explicitly, the default calculation is based on the values of "Close" prices.

When you call a custom indicator from mql5-program, the `Applied_Price` parameter or a handle of another indicator should be passed last, after all input variables of the custom indicator.

```

iDEMA

The function returns the handle of the Double Exponential Moving Average indicator. It has only one buffer.

```
int iDEMA(
    string          symbol,          // symbol name
    ENUM_TIMEFRAMES period,          // period
    int             ma_period,        // averaging period
    int             ma_shift,         // horizontal shift
    ENUM_APPLIED_PRICE applied_price // type of price or handle
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

ma_period

[in] Averaging period (bars count) for calculations.

ma_shift

[in] Shift of the indicator relative to the price chart.

applied_price

[in] The price used. Can be any of the price constants [ENUM_APPLIED_PRICE](#) or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

iDeMarker

The function returns the handle of the DeMarker indicator. It has only one buffer.

```
int iDeMarker(
    string      symbol,      // symbol name
    ENUM_TIMEFRAMES period,  // period
    int         ma_period    // averaging period
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

ma_period

[in] Averaging period (bars count) for calculations.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

Example:

iEnvelopes

The function returns the handle of the Envelopes indicator.

```
int iEnvelopes(
    string            symbol,           // symbol name
    ENUM_TIMEFRAMES   period,          // period
    int               ma_period,        // period for the average line calculation
    int               ma_shift,         // horizontal shift of the indicator
    ENUM_MA_METHOD     ma_method,       // type of smoothing
    ENUM_APPLIED_PRICE applied_price,    // type of price or handle
    double            deviation         // deviation of boundaries from the midline
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The NULL value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

ma period

[in] Averaging period for the main line.

ma shift

[in] The shift of the indicator relative to the price chart.

```
ma method
```

[in] Smoothing type. Can be one of the values of `ENUM_MA_METHOD`.

applied price

[in] The price used. Can be any of the price constants [ENUM_APPLIED_PRICE](#) or a handle of another indicator.

deviation

[in] The deviation from the main line (in percents).

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

Note

The buffer numbers: 0 - UPPER_LINE, 1 - LOWER_LINE.

```

iForce

The function returns the handle of the Force Index indicator. It has only one buffer.

```
int iForce(
    string          symbol,          // symbol name
    ENUM_TIMEFRAMES period,          // period
    int             ma_period,        // averaging period
    ENUM_MA_METHOD  ma_method,        // smoothing type
    ENUM_APPLIED_VOLUME applied_volume // volume type for calculation
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

ma_period

[in] Averaging period for the indicator calculations.

ma_method

[in] Smoothing type. Can be one of the values of [ENUM_MA_METHOD](#).

applied_volume

[in] The volume used. Can be one of the values of [ENUM_APPLIED_VOLUME](#).

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

iFractals

The function returns the handle of the Fractals indicator.

```
int iFractals(
    string      symbol,      // symbol name
    ENUM_TIMEFRAMES period   // period
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

Note

The buffer numbers are the following: 0 - UPPER_LINE, 1 - LOWER_LINE.

iFrAMA

The function returns the handle of the Fractal Adaptive Moving Average indicator. It has only one buffer.

```
int iFrAMA(
    string          symbol,          // symbol name
    ENUM_TIMEFRAMES period,          // period
    int             ma_period,        // averaging period
    int             ma_shift,         // horizontal shift on the chart
    ENUM_APPLIED_PRICE applied_price // type of price or handle
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

ma_period

[in] Period (bars count) for the indicator calculations.

ma_shift

[in] Shift of the indicator in the price chart.

applied_price

[in] The price used. Can be any of the price constants [ENUM_APPLIED_PRICE](#) or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

iGator

The function returns the handle of the Gator indicator. The Oscillator shows the difference between the blue and red lines of Alligator (upper histogram) and difference between red and green lines (lower histogram).

```
int iGator(
    string          symbol,          // symbol name
    ENUM_TIMEFRAMES period,          // period
    int             jaw_period,      // period for the calculation of the jaws
    int             jaw_shift,       // jaws horizontal shift
    int             teeth_period,    // period for the calculation of the teeth
    int             teeth_shift,     // teeth horizontal shift
    int             lips_period,     // period for the calculation of the lips
    int             lips_shift,      // lips horizontal shift
    ENUM_MA_METHOD  ma_method,      // type of smoothing
    ENUM_APPLIED_PRICE applied_price // type of price or handle
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

jaw_period

[in] Averaging period for the blue line (Alligator's Jaw).

jaw_shift

[in] The shift of the blue line relative to the price chart. It isn't directly connected with the visual shift of the indicator histogram.

teeth_period

[in] Averaging period for the red line (Alligator's Teeth).

teeth_shift

[in] The shift of the red line relative to the price chart. It isn't directly connected with the visual shift of the indicator histogram.

lips_period

[in] Averaging period for the green line (Alligator's lips).

lips_shift

[in] The shift of the green line relative to the price charts. It isn't directly connected with the visual shift of the indicator histogram.

ma_method

[in] Smoothing type. Can be one of the values of [ENUM_MA_METHOD](#).

applied_price

[in] The price used. Can be any of the price constants [ENUM_APPLIED_PRICE](#) or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

Note

Buffer numbers: 0 - UPPER_HISTOGRAM, 1 - color buffer of the upper histogram, 2 - LOWER_HISTOGRAM, 3 - color buffer of the lower histogram.

ilchimoku

The function returns the handle of the Ichimoku Kinko Hyo indicator.

```
int iIchimoku(
    string          symbol,          // symbol name
    ENUM_TIMEFRAMES period,         // period
    int             tenkan_sen,      // period of Tenkan-sen
    int             kijun_sen,       // period of Kijun-sen
    int             senkou_span_b    // period of Senkou Span B
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

tenkan_sen

[in] Averaging period for Tenkan Sen.

kijun_sen

[in] Averaging period for Kijun Sen.

senkou_span_b

[in] Averaging period for Senkou Span B.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

Note

The buffer numbers: 0 - TENKANSEN_LINE, 1 - KIJUNSEN_LINE, 2 - SENKOUSPANA_LINE, 3 - SENKOUSPANB_LINE, 4 - CHIKOSPAN_LINE.

```

iBWMFI

The function returns the handle of the Market Facilitation Index indicator. It has only one buffer.

```
int iBWMFI(
    string          symbol,          // symbol name
    ENUM_TIMEFRAMES period,          // period
    ENUM_APPLIED_VOLUME applied_volume // volume type for calculation
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

applied_volume

[in] The volume used. Can be one of the constants of [ENUM_APPLIED_VOLUME](#).

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

iMomentum

The function returns the handle of the Momentum indicator. It has only one buffer.

```
int iMomentum(
    string      symbol,           // symbol name
    ENUM_TIMEFRAMES period,      // period
    int         mom_period,       // averaging period
    ENUM_APPLIED_PRICE applied_price // type of price or handle
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

mom_period

[in] Averaging period (bars count) for the calculation of the price change.

applied_price

[in] The price used. Can be any of the price constants [ENUM_APPLIED_PRICE](#) or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

iMFI

The function returns the handle of the Money Flow Index indicator.

```
int iMFI(
    string          symbol,          // symbol name
    ENUM_TIMEFRAMES period,          // period
    int             ma_period,        // averaging period
    ENUM_APPLIED_VOLUME applied_volume // volume type for calculation
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

ma_period

[in] Averaging period (bars count) for the calculation.

applied_volume

[in] The volume used. Can be any of the [ENUM_APPLIED_VOLUME](#) values.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

Example:

iMA

The function returns the handle of the Moving Average indicator. It has only one buffer.

```
int iMA(
    string          symbol,          // symbol name
    ENUM_TIMEFRAMES period,          // period
    int             ma_period,        // averaging period
    int             ma_shift,         // horizontal shift
    ENUM_MA_METHOD  ma_method,        // smoothing type
    ENUM_APPLIED_PRICE applied_price // type of price or handle
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

ma_period

[in] Averaging period for the calculation of the moving average.

ma_shift

[in] Shift of the indicator relative to the price chart.

ma_method

[in] Smoothing type. Can be one of the [ENUM_MA_METHOD](#) values.

applied_price

[in] The price used. Can be any of the price constants [ENUM_APPLIED_PRICE](#) or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

```

iOsMA

The function returns the handle of the Moving Average of Oscillator indicator. The OsMA oscillator shows the difference between values of MACD and its signal line. It has only one buffer.

```
int iOsMA(
    string          symbol,          // symbol name
    ENUM_TIMEFRAMES period,          // period
    int             fast_ema_period, // period for Fast Moving Average
    int             slow_ema_period, // period for Slow Moving Average
    int             signal_period,   // averaging period for their difference
    ENUM_APPLIED_PRICE applied_price // type of price or handle
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

fast_ema_period

[in] Period for Fast Moving Average calculation.

slow_ema_period

[in] Period for Slow Moving Average calculation.

signal_period

[in] Averaging period for signal line calculation.

applied_price

[in] The price used. Can be any of the price constants [ENUM_APPLIED_PRICE](#) or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

Note

In some systems this oscillator is also known as MACD histogram.

```

iMACD

The function returns the handle of the Moving Averages Convergence/Divergence indicator. In systems where OsMA is called MACD Histogram, this indicator is shown as two lines. In the client terminal the Moving Averages Convergence/Divergence looks like a histogram.

```
int iMACD(
    string          symbol,          // symbol name
    ENUM_TIMEFRAMES period,          // period
    int             fast_ema_period,  // period for Fast average calculation
    int             slow_ema_period,  // period for Slow average calculation
    int             signal_period,    // period for their difference averaging
    ENUM_APPLIED_PRICE applied_price  // type of price or handle
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

fast_ema_period

[in] Period for Fast Moving Average calculation.

slow_ema_period

[in] Period for Slow Moving Average calculation.

signal_period

[in] Period for Signal line calculation.

applied_price

[in] The price used. Can be any of the price constants [ENUM_APPLIED_PRICE](#) or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

Note

The buffer numbers are the following: 0 - MAIN_LINE, 1 - SIGNAL_LINE.

iOBV

The function returns the handle of the On Balance Volume indicator. It has only one buffer.

```
int iOBV(
    string          symbol,          // symbol name
    ENUM_TIMEFRAMES period,          // period
    ENUM_APPLIED_VOLUME applied_volume // volume type for calculation
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

applied_volume

[in] The volume used. Can be any of the [ENUM_APPLIED_VOLUME](#) values.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

Example:

```

iSAR

The function returns the handle of the Parabolic Stop and Reverse system indicator. It has only one buffer.

```
int iSAR(
    string      symbol,      // symbol name
    ENUM_TIMEFRAMES period,  // period
    double      step,        // price increment step - acceleration factor
    double      maximum      // maximum value of step
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

step

[in] The step of price increment, usually 0.02.

maximum

[in] The maximum step, usually 0.2.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

Example:

iRSI

The function returns the handle of the Relative Strength Index indicator. It has only one buffer.

```
int iRSI(
    string          symbol,          // symbol name
    ENUM_TIMEFRAMES period,          // period
    int             ma_period,       // averaging period
    ENUM_APPLIED_PRICE applied_price // type of price or handle
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

ma_period

[in] Averaging period for the RSI calculation.

applied_price

[in] The price used. Can be any of the price constants [ENUM_APPLIED_PRICE](#) or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

    }

```

iRVI

The function returns the handle of the Relative Vigor Index indicator.

```
int iRVI(
    string      symbol,      // symbol name
    ENUM_TIMEFRAMES period,  // period
    int         ma_period    // averaging period
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

ma_period

[in] Averaging period for the RVI calculation.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

Note

The buffer numbers are the following: 0 - MAIN_LINE, 1 - SIGNAL_LINE.

```

iStdDev

The function returns the handle of the Standard Deviation indicator. It has only one buffer.

```
int iStdDev(
    string          symbol,          // symbol name
    ENUM_TIMEFRAMES period,          // period
    int             ma_period,        // averaging period
    int             ma_shift,         // horizontal shift
    ENUM_MA_METHOD  ma_method,        // smoothing type
    ENUM_APPLIED_PRICE applied_price // type of price or handle
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

ma_period

[in] Averaging period for the indicator calculations.

ma_shift

[in] Shift of the indicator relative to the price chart.

ma_method

[in] Type of averaging. Can be any of the [ENUM_MA_METHOD](#) values.

applied_price

[in] The price used. Can be any of the price constants [ENUM_APPLIED_PRICE](#) or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

iStochastic

The function returns the handle of the Stochastic Oscillator indicator.

```
int iStochastic(
    string      symbol,           // symbol name
    ENUM_TIMEFRAMES period,      // period
    int         Kperiod,         // K-period (number of bars for calculations)
    int         Dperiod,         // D-period (period of first smoothing)
    int         slowing,         // final smoothing
    ENUM_MA_METHOD ma_method,    // type of smoothing
    ENUM_STO_PRICE price_field   // stochastic calculation method
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

Kperiod

[in] Averaging period (bars count) for the %K line calculation.

Dperiod

[in] Averaging period (bars count) for the %D line calculation.

slowing

[in] Slowing value.

ma_method

[in] Type of averaging. Can be any of the [ENUM_MA_METHOD](#) values.

price_field

[in] Parameter of price selection for calculations. Can be one of the [ENUM_STO_PRICE](#) values.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

Note

The buffer numbers: 0 - MAIN_LINE, 1 - SIGNAL_LINE.

```

iTEMA

The function returns the handle of the Triple Exponential Moving Average indicator. It has only one buffer.

```
int iTEMA(
    string          symbol,          // symbol name
    ENUM_TIMEFRAMES period,          // period
    int             ma_period,        // averaging period
    int             ma_shift,         // horizontal shift of indicator
    ENUM_APPLIED_PRICE applied_price // type of price or handle
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

ma_period

[in] Averaging period (bars count) for calculation.

ma_shift

[in] Shift of indicator relative to the price chart.

applied_price

[in] The price used. Can be any of the price constants [ENUM_APPLIED_PRICE](#) or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

iTriX

The function returns the handle of the Triple Exponential Moving Averages Oscillator indicator. It has only one buffer.

```
int iTriX(
    string          symbol,          // symbol name
    ENUM_TIMEFRAMES period,          // period
    int             ma_period,       // averaging period
    ENUM_APPLIED_PRICE applied_price // type of price or handle
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

ma_period

[in] Averaging period (bars count) for calculations.

applied_price

[in] The price used. Can be any of the price constants [ENUM_APPLIED_PRICE](#) or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

Example:

```

}

```

iWPR

The function returns the handle of the Larry Williams' Percent Range indicator. It has only one buffer.

```
int iWPR(
    string      symbol,           // symbol name
    ENUM_TIMEFRAMES period,       // period
    int         calc_period       // averaging period
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

calc_period

[in] Period (bars count) for the indicator calculation.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

iVIDyA

The function returns the handle of the Variable Index Dynamic Average indicator. It has only one buffer.

```
int iVIDyA(
    string          symbol,          // symbol name
    ENUM_TIMEFRAMES period,          // period
    int             cmo_period,      // period for Chande Momentum
    int             ema_period,      // EMA smoothing period
    int             ma_shift,        // horizontal shift on the price chart
    ENUM_APPLIED_PRICE applied_price // type of price or handle
);
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

cmo_period

[in] Period (bars count) for the Chande Momentum Oscillator calculation.

ema_period

[in] EMA period (bars count) for smoothing factor calculation.

ma_shift

[in] Shift of the indicator relative to the price chart.

applied_price

[in] The price used. Can be any of the price constants [ENUM_APPLIED_PRICE](#) or a handle of another indicator.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

```

iVolumes

The function returns the handle of the Volumes indicator. It has an only one buffer.

```
int iVolumes(
    string          symbol,          // symbol name
    ENUM_TIMEFRAMES period,          // period
    ENUM_APPLIED_VOLUME applied_volume // volume type for calculation
)
```

Parameters

symbol

[in] The symbol name of the security, the data of which should be used to calculate the indicator. The [NULL](#) value means the current symbol.

period

[in] The value of the period can be one of the [ENUM_TIMEFRAMES](#) values, 0 means the current timeframe.

applied_volume

[in] The volume used. Can be any of the [ENUM_APPLIED_VOLUME](#) values.

Return Value

Returns the handle of a specified technical indicator, in case of failure returns [INVALID_HANDLE](#). The computer memory can be freed from an indicator that is no more utilized, using the [IndicatorRelease\(\)](#) function, to which the indicator handle is passed.

Working with Optimization Results

Functions for organizing custom processing of the optimization results in the strategy tester. They can be called during optimization in testing agents, as well as locally in Expert Advisors and scripts.

When you run an Expert Advisor in the strategy tester, you can create your own data array based on the simple types or [simple structures](#) (they do not contain strings, class objects or objects of dynamic arrays). This data set can be saved using the [FrameAdd\(\)](#) function in a special structure called a frame. During the optimization of an Expert Advisor, each agent can send a series of frames to the terminal. All the received frames are written in the *.MQD file named as the Expert Advisor in the terminal_directory\MQL5\Files\Tester folder. They are written in the order they are received from the agents. Receipt of a frame in the client terminal from a testing agent generates the [TesterPass](#) event.

Frames can be stored in the computer memory and in a file with the specified name. The MQL5 language sets no limitations on the number of frames.

Function	Action
FrameFirst	Moves a pointer of frame reading to the beginning and resets the previously set filter
FrameFilter	Sets the frame reading filter and moves the pointer to the beginning
FrameNext	Reads a frame and moves the pointer to the next one
FrameInputs	Receives input parameters , on which the frame is formed
FrameAdd	Adds a frame with data
ParameterGetRange	Receives data on the values range and the change step for an input variable when optimizing an Expert Advisor in the Strategy Tester
ParameterSetRange	Specifies the use of input variable when optimizing an Expert Advisor in the Strategy Tester: value, change step, initial and final values

See also

[Testing Statistics](#), [Properties of a Running MQL5 Program](#)

FrameFirst

Moves a pointer of frame reading to the beginning and resets a set filter.

```
bool FrameFirst();
```

Return Value

Returns true if successful, otherwise false. To get information about the error, call the [GetLastError\(\)](#) function.

FrameFilter

Sets the frame reading filter and moves the pointer to the beginning.

```
bool FrameFilter(  
    const string name,          // Public name/label  
    long id                    // Public ID  
);
```

Return Value

Returns true if successful, otherwise false. To get information about the error, call the [GetLastError\(\)](#) function.

Note

If an empty string is passed as the first parameter, the filter will work only with a numeric parameter, i.e. only frames with the specified id will be viewed. If the value of the second parameter is [ULONG_MAX](#), only a text filter works.

Call of [FrameFilter\("", ULONG_MAX\)](#) is equivalent to calling [FrameFirst\(\)](#), i.e. equal to not using any filter.

FrameNext

Reads a frame and moves the pointer to the next one. There are two variants of the function.

1. Calling to receive one numeric value

```
bool FrameNext(  
    ulong& pass,      // The number of a pass in the optimization, during which the  
    string& name,      // Public name/label  
    long& id,         // Public ID  
    double& value     // Value  
);
```

2. Calling to receive all the data of a frame

```
bool FrameNext(  
    ulong& pass,      // The number of a pass in the optimization, during which the  
    string& name,      // Public name/label  
    long& id,         // Public ID  
    double& value,    // Value  
    void& data[]      // Array of any type  
);
```

Parameters

pass

[out] The number of a pass during optimization in the strategy tester.

name

[out] The name of the identifier.

id

[out] The value of the identifier.

value

[out] A single numeric value.

data

[out] An array of any type.

Return Value

Returns true if successful, otherwise false. To get information about the error, call the [GetLastError\(\)](#) function.

Note

In the second version of the call, you must correctly handle the received data in the *data[]* array.

FrameInputs

Receives [input parameters](#), on which the frame with the specified pass number is formed.

```
bool FrameInputs(  
    ulong    pass,                // The number of a pass in the optimization  
    string&  parameters[],        // An array of strings of form "parameterN=valueN"  
    uint&    parameters_count     // The total number of parameters  
);
```

Parameters

pass

[out] The number of a pass during optimization in the strategy tester.

parameters

[out] A string array with the description of names and parameter values

parameters_count

[out] The number of elements in the array *parameters[]*.

Return Value

Returns true if successful, otherwise false. To get information about the error, call the [GetLastError\(\)](#) function.

Note

Having obtained the number of strings *parameters_count* in the *parameters[]* array, you can organize a loop to go through all records. This will help you find the values of input parameters of an Expert Advisor for the specified pass number.

FrameAdd

Adds a frame with data. There are two variants of the function.

1. Adding data from a file

```
bool FrameAdd(  
    const string name,      // Public name/label  
    long id,               // Public ID  
    double value,          // Value  
    const string filename   // Name of a data file  
);
```

2. Adding data from an array of any type

```
bool FrameAdd(  
    const string name,      // Public name/label  
    long id,               // Public ID  
    double value,          // Value  
    const void& data[]      // Array of any type  
);
```

Parameters

name

[in] Public frame label. It can be used for a filter in the [FrameFilter\(\)](#) function.

id

[in] A public identifier of the frame. It can be used for a filter in the [FrameFilter\(\)](#) function.

value

[in] A numeric value to write into the frame. It is used to transmit a single pass result like in the [OnTester\(\)](#) function.

filename

[in] The name of the file that contains data to add to the frame. The file must be located in the folder MQL5/Files.

data

[in] An array of any type to write into the frame. Passed by reference.

Return Value

Returns true if successful, otherwise false. To get information about the error, call the [GetLastError\(\)](#) function.

ParameterGetRange

Receives data on the values range and the change step for an [input variable](#) when optimizing an Expert Advisor in the Strategy Tester. There are 2 variants of the function.

1. Receiving data for the integer type input parameter

```
bool ParameterGetRange(
    const string name,           // parameter (input variable) name
    bool& enable,               // parameter optimization enabled
    long& value,                // parameter value
    long& start,                // initial value
    long& step,                 // change step
    long& stop                  // final value
);
```

2. Receiving data for the real type input parameter

```
bool ParameterGetRange(
    const string name,           // parameter (input variable) name
    double& enable,              // parameter optimization enabled
    double& value,               // parameter value
    double& start,               // initial value
    double& step,                // change step
    double& stop                 // final value
);
```

Parameters

name

[in] [input variable](#) ID. These variables are external parameters of an application. Their values can be specified when launching on a chart or during a single test.

enable

[out] Flag that this parameter can be used to enumerate the values during the optimization in the Strategy Tester.

value

[out] Parameter value.

start

[out] Initial parameter value during the optimization.

step

[out] Parameter change step when enumerating its values.

stop

[out] Final parameter value during the optimization.

Return Value

Returns true if successful, otherwise false. For information about the error, use the [GetLastError\(\)](#) function.

Note

The function can be called only from [OnTesterInit\(\)](#), [OnTesterPass\(\)](#) and [OnTesterDeinit\(\)](#) handlers. It has been introduced to receive Expert Advisor input parameters' values and variation ranges during the optimization in the Strategy Tester.

When called in [OnTesterInit\(\)](#), the obtained data can be used to redefine the rules for enumeration of any [input variable](#) using [ParameterSetRange\(\)](#) function. Therefore, new Start, Stop and Step values can be set and the input parameter can even be completely excluded from optimization regardless of the Strategy Tester settings. This allows you to manage the area of the input parameters during the optimization by excluding some parameters from the optimization depending on the Expert Advisor's key parameters' values.

Example:

```
#property description "Expert Advisor for ParameterGetRange() function demonstration."
#property description "Should be launched in the optimization mode of the Strategy Tester"

//--- input parameters
input int          Input1=1;
input double       Input2=2.0;
input bool         Input3=false;
input ENUM_DAY_OF_WEEK Input4=SUNDAY;

//+-----+
//| Expert initialization function |
//+-----+

int OnInit()
{
    //--- Expert Advisor is designed for operation only in the Strategy Tester
    if(!MQL5InfoInteger(MQL5_OPTIMIZATION))
    {
        MessageBox("Should be launched in the optimization mode of the Strategy Tester!");
        //--- finish the Expert Advisor operation in advance and remove from the chart
        return(INIT_FAILED);
    }

    //--- successful completion of initialization
    return(INIT_SUCCEEDED);
}

//+-----+
//| TesterInit function |
//+-----+

void OnTesterInit()
{
    //--- example for long type input parameter
    string name="Input1";
    bool enable;
    long par1,par1_start,par1_step,par1_stop;
    ParameterGetRange(name,enable,par1,par1_start,par1_step,par1_stop);
}
```

```

Print("First parameter");
PrintFormat("%s=%d  enable=%s  from %d to %d with step=%d",
            name,par1,(string)enable,par1_start,par1_stop,par1_step);
//--- example for double type input parameter
name="Input2";
double par2,par2_start,par2_step,par2_stop;
ParameterGetRange(name,enable,par2,par2_start,par2_step,par2_stop);
Print("Second parameter");
PrintFormat("%s=%G  enable=%s  from %G to %G with step=%G",
            name,par2,(string)enable,par2_start,par2_stop,par2_step);

//--- example for bool type input parameter
name="Input3";
long par3,par3_start,par3_step,par3_stop;
ParameterGetRange(name,enable,par3,par3_start,par3_step,par3_stop);
Print("Third parameter");
PrintFormat("%s=%s  enable=%s  from %s to %s",
            name,(string)par3,(string)enable,
            (string)par3_start,(string)par3_stop);

//--- example for enumeration type input parameter
name="Input4";
long par4,par4_start,par4_step,par4_stop;
ParameterGetRange(name,enable,par4,par4_start,par4_step,par4_stop);
Print("Fourth parameter");
PrintFormat("%s=%s  enable=%s  from %s to %s",
            name,EnumToString((ENUM_DAY_OF_WEEK)par4),(string)enable,
            EnumToString((ENUM_DAY_OF_WEEK)par4_start),
            EnumToString((ENUM_DAY_OF_WEEK)par4_stop));
}
//+-----+
//| TesterDeinit function |
//+-----+
void OnTesterDeinit()
{
//--- this message will be shown after optimization is complete
Print(__FUNCTION__," Optimization completed");
}

```

ParameterSetRange

Specifies the use of [input variable](#) when optimizing an Expert Advisor in the Strategy Tester: value, change step, initial and final values. There are 2 variants of the function.

1. Specifying the values for the integer type input parameter

```
bool ParameterSetRange(
    const string name,          // parameter (input variable) name
    bool enable,               // parameter optimization enabled
    long value,                // parameter value
    long start,                // initial value
    long step,                 // change step
    long stop                  // final value
);
```

2. Specifying the values for the real type input parameter

```
bool ParameterSetRange(
    const string name,          // parameter (input variable) name
    double enable,              // parameter optimization enabled
    double value,               // parameter value
    double start,               // initial value
    double step,                // change step
    double stop                 // final value
);
```

Parameters

name

[in] [input or sinput](#) variable ID. These variables are external parameters of an application. Their values can be specified when launching the program.

enable

[in] Enable this parameter to enumerate the values during the optimization in the Strategy Tester.

value

[in] Parameter value.

start

[in] Initial parameter value during the optimization.

step

[in] Parameter change step when enumerating its values.

stop

[in] Final parameter value during the optimization.

Return Value

Returns true if successful, otherwise false. For information about the error, use the [GetLastError\(\)](#) function.

Note

The function can be called only from [OnTesterInit\(\)](#) handler when launching optimization from the Strategy Tester. It is designed for specifying the parameter's range and change step. The parameter can be completely excluded from optimization regardless of the Strategy Tester settings. It also allows using the variables declared with sinput modifier in the optimization process.

ParameterSetRange() function allows you to manage an Expert Advisor optimization in the Strategy Tester depending on its key parameters' values by including or excluding required input parameters from the optimization and setting the required range and the change step.

Event Functions

This group contains functions for working with custom events and timer events. Besides this group, there are special functions for handling [predefined events](#).

Function	Action
EventSetMillisecondTimer	Launches event generator of the high-resolution timer with a period less than 1 second for the current chart
EventSetTimer	Starts the timer event generator with the specified periodicity for the current chart
EventKillTimer	Stops the generation of events by the timer in the current chart
EventChartCustom	Generates a custom event for the specified chart

See also

[Types of Chart Events](#)

EventSetMillisecondTimer

The function indicates to the client terminal that [timer](#) events should be generated at intervals less than one second for this Expert Advisor or indicator.

```
bool EventSetMillisecondTimer(  
    int milliseconds // number of milliseconds  
);
```

Parameters

milliseconds

[in] Number of milliseconds defining the frequency of timer events.

Return Value

In case of successful execution, returns true, otherwise - false. To receive an [error](#) code, [GetLastError\(\)](#) function should be called.

Note

This feature is designed for the cases when high-resolution timer is required. In other words, timer events should be received more frequently than once per second. If a conventional timer with the period of more than one second is enough for you, use [EventSetTimer\(\)](#).

The minimum interval of 1000 milliseconds is used in the strategy tester. In general, when the timer period is reduced, the testing time is increased, as the handler of timer events is called more often. When working in real-time mode, timer events are generated no more than 1 time in 10-16 milliseconds due to hardware limitations.

Usually, this function should be called from [OnInit\(\)](#) function or in class [constructor](#). To handle events coming from the timer, an Expert Advisor or an indicator should have [OnTimer\(\)](#) function.

Each Expert Advisor and each indicator work with its own timer receiving events solely from this timer. During mql5 application shutdown, the timer is forcibly destroyed in case it has been created but has not been disabled by [EventKillTimer\(\)](#) function.

Only one timer can be launched for each program. Each mql5 application and chart have their own queue of events where all newly arrived events are placed. If the queue already contains [Timer](#) event or this event is in the processing stage, then the new Timer event is not added to mql5 application queue.

EventSetTimer

The function indicates to the client terminal, that for this indicator or Expert Advisor, events from the [timer](#) must be generated with the specified periodicity.

```
bool EventSetTimer(  
    int seconds // number of seconds  
);
```

Parameters

seconds

[in] Number of seconds that determine the frequency of the timer event occurrence.

Return Value

In case of success returns true, otherwise false. In order to get an [error code](#), the [GetLastError\(\)](#) function should be called.

Note

Normally, this function must be called from the [OnInit\(\)](#) function or from a class [constructor](#). In order to handle events coming from the timer, the Expert Advisor must have the [OnTimer\(\)](#) function.

Every Expert Advisor, as well as every indicator works with its own timer and receives events only from it. As soon as a mql5 program stops operating, the timer is destroyed forcibly if it was created but hasn't been disabled by the [EventKillTimer\(\)](#) function.

For each program no more than one timer can be run. Each mql5 program and each chart has its own queue of events, in which all the newly received events are placed. If the [Timer](#) event is present in the queue or is being processed, the new Timer event will not be placed in the queue of the mql5 program.

EventKillTimer

Specifies the client terminal that is necessary to stop the generation of events from [Timer](#).

```
void EventKillTimer();
```

Return Value

No return value.

Note

Typically, this function must be called from a function [OnDeinit\(\)](#), if the [EventSetTimer\(\)](#) function has been called from [OnInit\(\)](#). This function can also be called from the class destructor, if the [EventSetTimer\(\)](#) function has been called in the [constructor](#) of this class.

Every Expert Advisor, as well as every indicator works with its own timer and receives events only from it. As soon as a mql5 program stops operating, the timer is destroyed forcibly if it was created but hasn't been disabled by the [EventKillTimer\(\)](#) function

EventChartCustom

The function generates a custom event for the specified chart.

```
bool EventChartCustom(
    long    chart_id,           // identifier of the event receiving chart
    ushort  custom_event_id,    // event identifier
    long    lparam,            // parameter of type long
    double  dparam,            // parameter of type double
    string  sparam             // string parameter of the event
);
```

Parameters

chart_id

[in] Chart identifier. 0 means the current chart.

custom_event_id

[in] ID of the user events. This identifier is automatically added to the value [CHARTEVENT_CUSTOM](#) and converted to the integer type.

lparam

[in] Event parameter of the long type passed to the [OnChartEvent](#) function.

dparam

[in] Event parameter of the double type passed to the [OnChartEvent](#) function.

sparam

[in] Event parameter of the string type passed to the [OnChartEvent](#) function. If the string is longer than 63 characters, it is truncated.

Return Value

Returns true if a custom event has been successfully placed in the events queue of the chart that receives the events. In case of failure, it returns false. Use [GetLastError\(\)](#) to get an error code.

Note

An Expert Advisor or indicator attached to the specified chart handles the event using the function [OnChartEvent](#)(int event_id, long& lparam, double& dparam, string& sparam).

For each type of event, the input parameters of the OnChartEvent() function have definite values that are required for the processing of this event. The events and values passed through this parameters are listed in the below table.

Event	Value of the id parameter	Value of the lparam parameter	Value of the dparam parameter	Value of the sparam parameter
Event of a keystroke	CHARTEVENT_KEYDOWN	code of a pressed key	Repeat count (the number of times the keystroke is	The string value of a bit mask describing the

			repeated as a result of the user holding down the key)	status of keyboard buttons
Mouse event (if property CHART_EVENT_MOUSE_MOVE =true is set for the chart)	CHARTEVENT_MOUSE_MOVE	the X coordinate	the Y coordinate	The string value of a bit mask describing the status of mouse buttons
Event of graphical object creation (if CHART_EVENT_OBJECT_CREATE =true is set for the chart)	CHARTEVENT_OBJECT_CREATE	—	—	Name of the created graphical object
Event of change of an object property via the properties dialog	CHARTEVENT_OBJECT_CHANGE	—	—	Name of the modified graphical object
Event of graphical object deletion (if CHART_EVENT_OBJECT_DELETE =true is set for the chart)	CHARTEVENT_OBJECT_DELETE	—	—	Name of the deleted graphical object
Event of a mouse click on the chart	CHARTEVENT_CLICK	the X coordinate	the Y coordinate	—
Event of a mouse click in a graphical object belonging to the chart	CHARTEVENT_OBJECT_CLICK	the X coordinate	the Y coordinate	Name of the graphical object, on which the event occurred
Event of a graphical object dragging using the mouse	CHARTEVENT_OBJECT_DRAG	—	—	Name of the moved graphical object
Event of the finished text editing in the entry box of the	CHARTEVENT_OBJECT_ENDEDIT	—	—	Name of the LabelEdit graphical object, in which text

LabelEdit graphical object				editing has completed
Event of changes on a chart	CHARTEVENT_CHART_CHANGE	—	—	—
ID of the user event under the N number	CHARTEVENT_CUSTOM+N	Value set by the EventChartCustom() function	Value set by the EventChartCustom() function	Value set by the EventChartCustom() function

Working with OpenCL

[OpenCL](#) programs are used for performing computations on video cards that support OpenCL 1.1 or higher. Modern video cards contain hundreds of small specialized processors that can simultaneously perform simple mathematical operations with incoming data streams. The OpenCL language organizes parallel computing and provides greater speed for a certain class of tasks.

In some graphic cards working with the [double](#) type numbers is disabled by default. This can lead to compilation error 5105. To enable support for the double type numbers, please add the following directive to your OpenCL program: [#pragma OPENCL EXTENSION cl_khr_fp64 : enable](#). However if a graphic card doesn't support double, enabling this directive won't be of help.

It is recommended to write the source code for OpenCL in separate CL files, which can later be included in the MQL5 program using the [resource variables](#).

Functions for running programs in OpenCL:

Function	Action
CLHandleType	Returns the type of an OpenCL handle as a value of the ENUM_OPENCL_HANDLE_TYPE enumeration
CLGetInfoInteger	Returns the value of an integer property for an OpenCL object or device
CLContextCreate	Creates an OpenCL context
CLContextFree	Removes an OpenCL context
CLGetDeviceInfo	Receives device property from OpenCL driver
CLProgramCreate	Creates an OpenCL program from a source code
CLProgramFree	Removes an OpenCL program
CLKernelCreate	Creates an OpenCL start function
CLKernelFree	Removes an OpenCL start function
CLSetKernelArg	Sets a parameter for the OpenCL function
CLSetKernelArgMem	Sets an OpenCL buffer as a parameter of the OpenCL function
CLSetKernelArgMemLocal	Sets the local buffer as an argument of the kernel function
CLBufferCreate	Creates an OpenCL buffer
CLBufferFree	Deletes an OpenCL buffer
CLBufferWrite	Writes an array into an OpenCL buffer
CLBufferRead	Reads an OpenCL buffer into an array
CLExecute	Runs an OpenCL program

<u>CLExecutionStatus</u>	Returns the OpenCL program execution status
--	---

See also[OpenCL](#), [Resources](#)

CLHandleType

Returns the type of an OpenCL handle as a value of the `ENUM_OPENCL_HANDLE_TYPE` enumeration.

```
ENUM_OPENCL_HANDLE_TYPE CLHandleType(  
    int handle    // Handle of an OpenCL object  
);
```

Parameters

handle

[in] A handle to an OpenCL object: a context, a kernel or an OpenCL program.

Return Value

The type of the OpenCL handle as a value of the [ENUM_OPENCL_HANDLE_TYPE](#) enumeration.

ENUM_OPENCL_HANDLE_TYPE

Identifier	Description
OPENCL_INVALID	Incorrect handle
OPENCL_CONTEXT	A handle of the OpenCL context
OPENCL_PROGRAM	A handle of the OpenCL program
OPENCL_KERNEL	A handle of the OpenCL kernel
OPENCL_BUFFER	A handle of the OpenCL buffer

CLGetInfoInteger

Returns the value of an integer property for an OpenCL object or device.

```
long CLGetInfoInteger(
    int handle,                // The handle of the OpenCL object or the number of the OpenCL device
    ENUM_OPENCL_PROPERTY_INTEGER prop // Requested property
);
```

Parameters

handle

[in] A handle to the OpenCL object or number of the OpenCL device. Numbering of OpenCL devices starts with zero.

prop

[in] The type of a requested property from the [ENUM_OPENCL_PROPERTY_INTEGER](#) enumeration, the value of which you want to obtain.

Return Value

The value of the property if successful or -1 in case of an error. For information about the error, use the [GetLastError\(\)](#) function.

ENUM_OPENCL_PROPERTY_INTEGER

Identifier	Description	Type
CL_DEVICE_COUNT	The number of devices with OpenCL support. This property does not require specification of the first parameter, i.e. you can pass a zero value for the <i>handle</i> parameter.	int
CL_DEVICE_TYPE	Type of device	ENUM_CL_DEVICE_TYPE
CL_DEVICE_VENDOR_ID	Unique vendor identifier	uint
CL_DEVICE_MAX_COMPUTE_UNITS	Number of parallel calculated tasks in OpenCL device. One working group solves one computational task. The lowest value is 1	uint
CL_DEVICE_MAX_CLOCK_FREQUENCY	Highest set frequency of the device in MHz.	uint
CL_DEVICE_GLOBAL_MEM_SIZE	Size of the global memory of the device in bytes	ulong
CL_DEVICE_LOCAL_MEM_SIZE	Size of the processed data (scene) local memory in bytes	uint

CL_BUFFER_SIZE	Actual size of the OpenCL buffer in bytes	ulong
CL_DEVICE_MAX_WORK_GROUP_SIZE	The total number of the local working groups available for an OpenCL device.	ulong
CL_KERNEL_WORK_GROUP_SIZE	The total number of the local working groups available for an OpenCL program.	ulong
CL_KERNEL_LOCAL_MEM_SIZE	Size of the local memory (in bytes) used by an OpenCL program for solving all parallel tasks in a group. Use CL_DEVICE_LOCAL_MEM_SIZE to receive the maximum available value	ulong
CL_KERNEL_PRIVATE_MEM_SIZE	The minimum size of the private memory (in bytes) used by each task in the OpenCL program kernel.	ulong

The `ENUM_CL_DEVICE_TYPE` enumeration contains possible types of devices supporting OpenCL. You can receive the type of device by its number or the handle of the OpenCL object by calling `CLGetInfoInteger(handle_or_deviceN, CL_DEVICE_TYPE)`.

ENUM_CL_DEVICE_TYPE

Identifier	Description
CL_DEVICE_ACCELERATOR	Dedicated OpenCL accelerators (for example, the IBM CELL Blade). These devices communicate with the host processor using a peripheral interconnect such as PCIe.
CL_DEVICE_CPU	An OpenCL device that is the host processor. The host processor runs the OpenCL implementations and is a single or multi-core CPU.
CL_DEVICE_GPU	An OpenCL device that is a GPU.
CL_DEVICE_DEFAULT	The default OpenCL device in the system. The default device cannot be a <code>CL_DEVICE_TYPE_CUSTOM</code> device.
CL_DEVICE_CUSTOM	Dedicated accelerators that do not support programs written in OpenCL C.

Example:

```
void OnStart()
```

```
{
    int cl_ctx;
    //--- initialize OpenCL context
    if((cl_ctx=CLContextCreate(CL_USE_GPU_ONLY))==INVALID_HANDLE)
    {
        Print("OpenCL not found");
        return;
    }
    //--- Display general information about OpenCL device
    Print("OpenCL type: ",EnumToString((ENUM_CL_DEVICE_TYPE)CLGetInfoInteger(cl_ctx,CL_DEVICE_TYPE)));
    Print("OpenCL vendor ID: ",CLGetInfoInteger(cl_ctx,CL_DEVICE_VENDOR_ID));
    Print("OpenCL units: ",CLGetInfoInteger(cl_ctx,CL_DEVICE_MAX_COMPUTE_UNITS));
    Print("OpenCL freq: ",CLGetInfoInteger(cl_ctx,CL_DEVICE_MAX_CLOCK_FREQUENCY)," MHz");
    Print("OpenCL global mem: ",CLGetInfoInteger(cl_ctx,CL_DEVICE_GLOBAL_MEM_SIZE)," bytes");
    Print("OpenCL local mem: ",CLGetInfoInteger(cl_ctx,CL_DEVICE_LOCAL_MEM_SIZE)," bytes");
    //---
}
```

CLGetInfoString

Returns string value of a property for OpenCL object or device.

```
bool CLGetInfoString(  
    int handle, // OpenCL object handle or OpenCL device number  
    ENUM_OPENCL_PROPERTY_STRING prop, // requested property  
    string& value // referenced string  
);
```

Parameters

- handle*
- [in] OpenCL object handle or OpenCL device number. The numbering of OpenCL devices starts with zero.
- prop*
- [in] Type of requested property from [ENUM_OPENCL_PROPERTY_STRING](#) enumeration, the value of which should be obtained.
- value*
- [out] String for receiving the property value.

Return Value

true if successful, otherwise false. For information about the error, use the [GetLastError\(\)](#) function.

ENUM_OPENCL_PROPERTY_STRING

Identifier	Description
CL_PLATFORM_PROFILE	CL_PLATFORM_PROFILE - OpenCL Profile. Profile name may be one of the following values: <ul style="list-style-type: none">FULL_PROFILE - implementation supports OpenCL (functionality is defined as the part of the kernel specification without requiring additional extensions for OpenCL support);EMBEDDED_PROFILE - implementation supports OpenCL as a supplement. Amended profile is defined as a subset for each OpenCL version.
CL_PLATFORM_VERSION	OpenCL version
CL_PLATFORM_VENDOR	Platform vendor name
CL_PLATFORM_EXTENSIONS	List of extensions supported by the platform. Extension names should be supported by all devices related to this platform
CL_DEVICE_NAME	Device name
CL_DEVICE_VENDOR	Vendor name

CL_DRIVER_VERSION	OpenCL driver version in major_number.minor_number format
CL_DEVICE_PROFILE	OpenCL device profile. Profile name may be one of the following values: <ul style="list-style-type: none"> • FULL_PROFILE - implementation supports OpenCL (functionality is defined as the part of the kernel specification without requiring additional extensions for OpenCL support); • EMBEDDED_PROFILE - implementation supports OpenCL as a supplement. Amended profile is defined as a subset for each OpenCL version.
CL_DEVICE_VERSION	OpenCL version in "OpenCL<space><major_version.minor_version><space><vendor-specific information>" format
CL_DEVICE_EXTENSIONS	List of extensions supported by the device. The list may contain extensions supported by the vendor, as well as one or more approved names: <ul style="list-style-type: none"> cl_khr_int64_base_atomics cl_khr_int64_extended_atomics cl_khr_fp16 cl_khr_gl_sharing cl_khr_gl_event cl_khr_d3d10_sharing cl_khr_dx9_media_sharing cl_khr_d3d11_sharing
CL_DEVICE_BUILT_IN_KERNELS	The list of supported kernels separated by ";".
CL_DEVICE_OPENCL_C_VERSION	The maximum version supported by the compiler for this device. Version format: "OpenCL<space>C<space><major_version.minor_version><space><vendor-specific information> "

Example:

```

void OnStart()
{
    int cl_ctx;
    string str;
    //--- initialize OpenCL context
    if ((cl_ctx=CLContextCreate(CL_USE_GPU_ONLY)) == INVALID_HANDLE)
    {
        Print("OpenCL not found");
        return;
    }
    //--- Display information about the platform
    if (CLGetInfoString(cl_ctx, CL_PLATFORM_NAME, str))
        Print("OpenCL platform name: ", str);
}

```

```

    if (CLGetInfoString(cl_ctx, CL_PLATFORM_VENDOR, str))
        Print("OpenCL platform vendor: ", str);
    if (CLGetInfoString(cl_ctx, CL_PLATFORM_VERSION, str))
        Print("OpenCL platform ver: ", str);
    if (CLGetInfoString(cl_ctx, CL_PLATFORM_PROFILE, str))
        Print("OpenCL platform profile: ", str);
    if (CLGetInfoString(cl_ctx, CL_PLATFORM_EXTENSIONS, str))
        Print("OpenCL platform ext: ", str);
//--- Display information about the device
    if (CLGetInfoString(cl_ctx, CL_DEVICE_NAME, str))
        Print("OpenCL device name: ", str);
    if (CLGetInfoString(cl_ctx, CL_DEVICE_PROFILE, str))
        Print("OpenCL device profile: ", str);
    if (CLGetInfoString(cl_ctx, CL_DEVICE_BUILT_IN_KERNELS, str))
        Print("OpenCL device kernels: ", str);
    if (CLGetInfoString(cl_ctx, CL_DEVICE_EXTENSIONS, str))
        Print("OpenCL device ext: ", str);
    if (CLGetInfoString(cl_ctx, CL_DEVICE_VENDOR, str))
        Print("OpenCL device vendor: ", str);
    if (CLGetInfoString(cl_ctx, CL_DEVICE_VERSION, str))
        Print("OpenCL device ver: ", str);
    if (CLGetInfoString(cl_ctx, CL_DEVICE_OPENCL_C_VERSION, str))
        Print("OpenCL open c ver: ", str);
//--- Display general information about the OpenCL device
    Print("OpenCL type: ", EnumToString((ENUM_CL_DEVICE_TYPE) CLGetInfoInteger(cl_ctx, CL_
    Print("OpenCL vendor ID: ", CLGetInfoInteger(cl_ctx, CL_DEVICE_VENDOR_ID));
    Print("OpenCL units: ", CLGetInfoInteger(cl_ctx, CL_DEVICE_MAX_COMPUTE_UNITS));
    Print("OpenCL freq: ", CLGetInfoInteger(cl_ctx, CL_DEVICE_MAX_CLOCK_FREQUENCY));
    Print("OpenCL global mem: ", CLGetInfoInteger(cl_ctx, CL_DEVICE_GLOBAL_MEM_SIZE));
    Print("OpenCL local mem: ", CLGetInfoInteger(cl_ctx, CL_DEVICE_LOCAL_MEM_SIZE));
//---
}

```

CLContextCreate

Creates an OpenCL context and returns its handle.

```
int CLContextCreate(  
    int device    // Serial number of the OpenCL device or macro  
);
```

Parameter

device

[in] The ordinal number of the OpenCL-device in the system. Instead of a specific number, you can specify one of the following values:

- CL_USE_ANY - any available device with OpenCL support is allowed;
- CL_USE_CPU_ONLY - only OpenCL emulation on CPU is allowed;
- CL_USE_GPU_ONLY - OpenCL emulation is prohibited and only specialized devices with OpenCL support (video cards) can be used.

Return Value

A handle to the OpenCL context if successful, otherwise -1. For information about the error, use the [GetLastError\(\)](#) function.

CLContextFree

Removes an OpenCL context.

```
void CLContextFree(  
    int context    // Handle to an OpenCL context  
);
```

Parameters

context

[in] Handle of the OpenCL context.

Return Value

None. In the case of an internal error the value of [_LastError](#) changes. For information about the error, use the [GetLastError\(\)](#) function.

CLGetDeviceInfo

The function receives device property from OpenCL driver.

```
bool CLGetDeviceInfo(  
    int      handle,           // OpenCL device handle  
    int      property_id,      // requested property ID  
    uchar&   data[],          // array for receiving data  
    uint&    size              // shift in the array elements, default value is 0  
);
```

Parameters

handle

[in] OpenCL device index or OpenCL handle created by [CLContextCreate\(\)](#) function.

property_id

[in] ID of the OpenCL device property that should be received. The values can be of one of the predetermined ones listed in the [table below](#).

data[]

[out] The array for receiving data on the requested property.

size

[out] Size of the received data in the array *data[]*.

Return Value

true if successful, otherwise false. For information about the error, use the [GetLastError\(\)](#) function.

Note

For one-dimensional arrays, the number of the element, from which data reading for OpenCL buffer starts, is calculated considering [AS_SERIES](#) flag.

The list of available IDs of OpenCL device properties

Exact description of the property and its functions can be found at [the official OpenCL web site](#).

```

CLProgramCreate

Creates an OpenCL program from a source code.

```
int CLProgramCreate(
    int          context,    // Handle to an OpenCL context
    const string source      // Source code
);
```

An overloaded function version creates an OpenCL program and writes compiler messages into the passed string.

```
int CLProgramCreate(
    int          context,    // Handle to an OpenCL context
    const string source,    // Source code
    string       &build_log // A string for receiving the compilation log
);
```

Parameters

context

[in] Handle of the OpenCL context.

source

[in] String with the source code of the OpenCL program.

&build_log

[in] A string for receiving the OpenCL compiler messages.

Return Value

A handle to an OpenCL object if successful. In case of error -1 is returned. For information about the error, use the [GetLastError\(\)](#) function.

Note

At the moment, the following error codes are used:

- `ERR_OPENCL_INVALID_HANDLE` - invalid handle to the context OpenCL.
- `ERR_INVALID_PARAMETER` - invalid string parameter.
- `ERR_NOT_ENOUGH_MEMORY` - not enough memory to complete operation.
- `ERR_OPENCL_PROGRAM_CREATE` - internal error of OpenCL or compilation error.

In some graphic cards working with the [double](#) type numbers is disabled by default. This can lead to compilation error 5105. To enable support for the double type numbers, please add the following directive to your OpenCL program: `#pragma OPENCL EXTENSION cl_khr_fp64 : enable`. However if a graphic card doesn't support double, enabling this directive won't be of help.

Example:

```
//+-----+
//| OpenCL kernel |
//+-----+
const string
```

```

cl_src=
    //--- by default some GPU doesn't support doubles
    //--- cl_khr_fp64 directive is used to enable work with doubles
    "#pragma OPENCL EXTENSION cl_khr_fp64 : enable      \r\n"
    //--- OpenCL kernel function
    "__kernel void Test_GPU(__global double *data,      \r\n"
    "                        const   int N,              \r\n"
    "                        const   int total_arrays)   \r\n"
    "    {                                              \r\n"
    "        uint kernel_index=get_global_id(0);        \r\n"
    "        if (kernel_index>total_arrays) return;      \r\n"
    "        uint local_start_offset=kernel_index*N;    \r\n"
    "        for(int i=0; i<N; i++)                      \r\n"
    "        {                                          \r\n"
    "            data[i+local_start_offset] *= 2.0;      \r\n"
    "        }                                          \r\n"
    "    }                                              \r\n";

//+-----+
//| Test_CPU                                     |
//+-----+
bool Test_CPU(double &data[],const int N,const int id,const int total_arrays)
{
    //--- check array size
    if(ArraySize(data)==0) return(false);

```

```
//---  
    return(0);  
}
```

CLProgramFree

Removes an OpenCL program.

```
void CLProgramFree(  
    int program    // Handle to an OpenCL object  
);
```

Parameters

program

[in] Handle of the OpenCL object.

Return Value

None. In the case of an internal error the value of [_LastError](#) changes. For information about the error, use the [GetLastError\(\)](#) function.

CLKernelCreate

Creates the OpenCL program kernel and returns its handle.

```
int  CLKernelCreate(  
    int          program,          // Handle to an OpenCL object  
    const string kernel_name      // Kernel name  
);
```

Parameters

program

[in] Handle to an object of the OpenCL program.

kernel_name

[in] The name of the kernel function in the appropriate OpenCL program, in which execution begins.

Return Value

A handle to an OpenCL object if successful. In case of error -1 is returned. For information about the error, use the [GetLastError\(\)](#) function.

Note

At the moment, the following error codes are used:

- ERR_OPENCL_INVALID_HANDLE - invalid handle to OpenCL program.
- ERR_INVALID_PARAMETER - invalid string parameter.
- ERR_OPENCL_TOO_LONG_KERNEL_NAME - kernel name contains more than 127 characters.
- ERR_OPENCL_KERNEL_CREATE - internal error occurred while creating an OpenCL object.

CLKernelFree

Removes an OpenCL start function.

```
void CLKernelFree(  
    int kernel    // Handle to the kernel of an OpenCL program  
);
```

Parameters

kernel_name

[in] Handle of the kernel object.

Return Value

None. In the case of an internal error the value of [_LastError](#) changes. For information about the error, use the [GetLastError\(\)](#) function.

CLSetKernelArg

Sets a parameter for the OpenCL function.

```
bool CLSetKernelArg(  
    int    kernel,          // Handle to the kernel of an OpenCL program  
    uint   arg_index,       // The number of the argument of the OpenCL function  
    void   arg_value        // Source code  
);
```

Parameters

kernel

[in] Handle to a kernel of the OpenCL program.

arg_index

[in] The number of the function argument, numbering starts with zero.

arg_value

[in] The value of the function argument.

Return Value

Returns true if successful, otherwise returns false. For information about the error, use the [GetLastError\(\)](#) function.

Note

At the moment, the following error codes are used:

- ERR_INVALID_PARAMETER,
- ERR_OPENCL_INVALID_HANDLE - invalid handle to the OpenCL kernel.
- ERR_OPENCL_SET_KERNEL_PARAMETER - internal error of OpenCL.

CLSetKernelArgMem

Sets an OpenCL buffer as a parameter of the OpenCL function.

```
bool CLSetKernelArgMem(  
    int    kernel,           // Handle to the kernel of an OpenCL program  
    uint   arg_index,       // The number of the argument of the OpenCL function  
    int    cl_mem_handle     // Handle to OpenCL buffer  
);
```

Parameters

kernel

[in] Handle to a kernel of the OpenCL program.

arg_index

[in] The number of the function argument, numbering starts with zero.

cl_mem_handle

[in] A handle to an OpenCL buffer.

Return Value

Returns true if successful, otherwise returns false. For information about the error, use the [GetLastError\(\)](#) function.

CLSetKernelArgMemLocal

Sets the local buffer as an argument of the kernel function.

```
bool CLSetKernelArgMemLocal(  
    int    kernel,           // handle to a kernel of an OpenCL program  
    uint   arg_index,       // number of the OpenCL function argument  
    ulong  local_mem_size   // buffer size  
);
```

Parameters

kernel

[in] Handle to a kernel of the OpenCL program.

arg_index

[in] The number of the function argument, numbering starts with zero.

local_mem_size

[in] Buffer size in bytes.

Return Value

Returns true if successful, otherwise returns false. For information about the error, use the [GetLastError\(\)](#) function.

CLBufferCreate

Creates an OpenCL buffer and returns its handle.

```
int CLBufferCreate(  
    int    context,    // Handle to an OpenCL context  
    uint   size,       // Buffer size  
    uint   flags       // Flags combination which specify properties of OpenCL buffer  
);
```

Parameters

context

[in] A handle to context OpenCL.

size

[in] Buffer size in bytes.

flags

[in] Buffer properties that are set using a combination of flags: CL_MEM_READ_WRITE, CL_MEM_WRITE_ONLY, CL_MEM_READ_ONLY, CL_MEM_ALLOC_HOST_PTR.

Return Value

A handle to an OpenCL buffer if successful. In case of error -1 is returned. For information about the error, use the [GetLastError\(\)](#) function.

Note

At the moment, the following error codes are used:

- ERR_OPENCL_INVALID_HANDLE - invalid handle to OpenCL context.
- ERR_NOT_ENOUGH_MEMORY - insufficient memory.
- ERR_OPENCL_BUFFER_CREATE - internal error creating buffers.

CLBufferFree

Deletes an OpenCL buffer.

```
void CLBufferFree(  
    int    buffer    // Handle to an OpenCL buffer  
);
```

Parameters

buffer

[in] A handle to an OpenCL buffer.

Return Value

None. In the case of an internal error the value of [_LastError](#) changes. For information about the error, use the [GetLastError\(\)](#) function.

CLBufferWrite

Writes into the OpenCL buffer and returns the number of written elements.

```
uint CLBufferWrite(
    int          buffer,           // A handle to the OpenCL buffer
    const void&  data[],          // An array of values
    uint         buffer_offset=0,  // An offset in the OpenCL buffer in bytes,
    uint         data_offset=0,    // An offset in the array in elements, 0 by
    uint         data_count=WHOLE_ARRAY // The number of values from the array for
);
```

Parameters

buffer

[in] A handle of the OpenCL buffer.

data[]

[in] An array of values that should be written in the OpenCL buffer. Passed by reference.

buffer_offset

[in] An offset in the OpenCL buffer in bytes, from which writing begins. By default, writing start with the very beginning of the buffer.

data_offset

[in] The index of the first array element, starting from which values from the array are written in the OpenCL buffer. By default, values from the very beginning of the array are taken.

data_count

[in] The number of values that should be written. All the values of the array, by default.

Return Value

The number of written elements. 0 is returned in case of an error. For information about the error, use the [GetLastError\(\)](#) function.

Note

For one-dimensional arrays, the number of the element, with which reading of data for writing into an OpenCL buffer begins, is calculated taking into account the [AS_SERIES](#) flags.

An array of two or more dimensions is presented as one-dimensional. In this case, *data_offset* is the number of elements that should be skipped in the presentation, not the number of elements in the first dimension.

CLBufferRead

Reads an OpenCL buffer into an array and returns the number of read elements.

```
uint CLBufferRead(  
    int          buffer,           // A handle to the OpenCL buffer  
    const void&  data[],          // An array of values  
    uint         buffer_offset=0,  // An offset in the OpenCL buffer in bytes,  
    uint         data_offset=0,    // An offset in the array in elements, 0 by  
    uint         data_count=WHOLE_ARRAY // The number of values from the buffer for  
);
```

Parameters

buffer

[in] A handle of the OpenCL buffer.

data[]

[in] An array for receiving values from the OpenCL buffer. Passed by reference.

buffer_offset

[in] An offset in the OpenCL buffer in bytes, from which reading begins. By default, reading start with the very beginning of the buffer.

data_offset

[in] The index of the first array element for writing the values of the OpenCL buffer. By default, writing of the read values into an array starts from the zero index.

data_count

[in] The number of values that should be read. The whole OpenCL buffer is read by default.

Return Value

The number of read elements. 0 is returned in case of an error. For information about the error, use the [GetLastError\(\)](#) function.

Note

For one-dimensional arrays, the number of the element, into which writing of data into an OpenCL buffer begins, is calculated taking into account the [AS_SERIES](#) flags.

An array of two or more dimensions is presented as one-dimensional. In this case, *data_offset* is the number of elements that should be skipped in the presentation, not the number of elements in the first dimension.

CLExecute

The function runs an OpenCL program. There are 3 versions of the function:

1. Launching kernel functions using one kernel

```
bool CLExecute(
    int          kernel           // Handle to the kernel of an OpenCL program
);
```

2. Launching several kernel copies (OpenCL function) with task space description

```
bool CLExecute(
    int          kernel,           // Handle to the kernel of an OpenCL program
    uint         work_dim,         // Dimension of the tasks space
    const uint&  global_work_offset[], // Initial offset in the tasks space
    const uint&  global_work_size[]  // Total number of tasks
);
```

3. Launching several kernel copies (OpenCL function) with task space description and specification of the size of the group's local task subset

```
bool CLExecute(
    int          kernel,           // Handle to the kernel of an OpenCL program
    uint         work_dim,         // Dimension of the tasks space
    const uint&  global_work_offset[], // Initial offset in the tasks space
    const uint&  global_work_size[],  // Total number of tasks
    const uint&  local_work_size[]    // Number of tasks in the local group
);
```

Parameters

kernel

[in] Handle to the OpenCL kernel.

work_dim

[in] Dimension of the tasks space.

global_work_offset[]

[in] Initial offset in the tasks space.

global_work_size[]

[in] The size of a subset of tasks.

local_work_size[]

[in] The size of the group's local task subset.

Return Value

Returns true if successful, otherwise returns false. For information about the error, use the [GetLastError\(\)](#) function.

Note

Consider the use of the parameters in the following example:

- *work_dim* specifies the size of *work_items[]* array that describes the tasks. If *work_dim*=3, three-dimensional array *work_items[N1, N2, N3]* is used.
- *global_work_size[]* contains the values that set the *work_items[]* array size. If *work_dim*=3, *global_work_size[3]* array can be {40, 100, 320}. Then we have *work_items[40, 100, 320]*. So, the total number of tasks is $40 \times 100 \times 320 = 1\,280\,000$.
- *local_work_size[]* sets the subset of the tasks that will be executed by the specified kernel of OpenCL program. Its size is equal to *work_items[]* size and allows to split the common task subset into smaller subsets without loss of remainder in division. In fact, the size of *local_work_size[]* array should be selected so that the *work_items[]* global task set will be split into smaller subsets. In this example *local_work_size[3]={10, 10, 10}* will be OK, as *work_items[40, 100, 320]* can be gathered from *local_items[10, 10, 10]* array without division remainder.

CLExecutionStatus

Returns the OpenCL program execution status.

```
bool CLExecutionStatus(  
    int    kernel           // handle to a kernel of an OpenCL program  
);
```

Parameters

kernel

[in] Handle to a kernel of the OpenCL program.

Return Value

Returns the OpenCL program status. The value can be one of the following:

- CL_COMPLETE=0 - program complete,
- CL_RUNNING=1 - running,
- CL_SUBMITTED=2 - submitted for execution,
- CL_QUEUED=3 - queued,
- -1 (minus one) - error occurred when executing CLExecutionStatus().

Standard Library

This group of chapters contains the technical details of the MQL5 Standard Library and descriptions of all its key components.

MQL5 Standard Library is written in MQL5 and is designed to facilitate writing programs (indicators, scripts, experts) for end users. Library provides convenient access to the most of the internal MQL5 functions.

MQL5 Standard Library is placed in the working directory of the terminal in the 'Include' folder.

Multiple libraries are provided to perform calculations in various areas of mathematics:

- [Statistics](#) - functions for working with various distributions of the Probability theory
- [Fuzzy logic](#) - library that implements Mamdani and Sugeno fuzzy inference systems
- [ALGLIB](#) - data analysis (clustering, decision trees, linear regression, neural networks), solving differential equations, Fourier transform, numerical integration, optimization problems, statistical analysis, and more.

Statistics

The Statistical Library provides a convenient way of working with the basic statistical distributions.

The library provides 5 functions for each distribution:

1. Calculation of probability density - functions of the form `MathProbabilityDensityX()`
2. Calculation of probabilities - functions of the form `MathCumulativeDistributionX()`
3. Calculation of distribution quantiles - functions of the form `MathQuantileX()`
4. Generation of random numbers with the specified distribution - functions of the form `MathRandomX()`
5. Calculation of the theoretical moments of the distributions - functions of the form `MathMomentsX()`

In addition to calculation of values for the individual random variables, the library also provides overloads for the functions, which perform the same calculations for arrays.

Statistical Characteristics

This group of functions calculates the Statistical Characteristics of the array elements:

- mean,
- variance,
- skewness,
- kurtosis,
- median,
- root-mean-square and
- standard deviation.

Function	Description
MathMean	Calculates the mean (first moment) of array elements
MathVariance	Calculates the variance (second moment) of array elements
MathSkewness	Calculates the skewness (third moment) of array elements
MathKurtosis	Calculates the kurtosis (fourth moment) of array elements
MathMoments	Calculates the first 4 moments (mean, variance, skewness, kurtosis) of array elements
MathMedian	Calculates the median value of array elements
MathStandardDeviation	Calculates the standard deviation of array elements
MathAverageDeviation	Calculates the average absolute deviation of array elements

MathMean

Calculates the mean (first moment) of array elements. Analog of the [mean\(\)](#) in R.

```
double MathMean(  
    const double& array[],           // array with data  
    const int     start=0,           // initial index  
    const int     count=WHOLE_ARRAY // the number of elements  
);
```

Parameters

array

[in] Array with data for calculation of the mean.

start=0

[in] Initial index for calculation.

count=WHOLE_ARRAY

[in] The number of elements for calculation.

Return Value

The mean of array elements. In case of error it returns [NaN](#) (not a number).

MathVariance

Calculates the variance (second moment) of array elements. Analog of the [var\(\)](#) in R.

```
double MathVariance(  
    const double& array[],           // array with data  
    const int     start=0,           // initial index  
    const int     count=WHOLE_ARRAY // the number of elements  
);
```

Parameters

array

[in] Array with data for calculation.

start=0

[in] Initial index for calculation.

count=WHOLE_ARRAY

[in] The number of elements for calculation.

Return Value

Variance of array elements. In case of error it returns [NaN](#) (not a number).

MathSkewness

Calculates the skewness (third moment) of array elements. Analog of the [skewness\(\)](#) in R (e1071 library).

```
double MathSkewness(  
    const double& array[],           // array with data  
    const int     start=0,           // initial index  
    const int     count=WHOLE_ARRAY // the number of elements  
);
```

Parameters

array

[in] Array with data for calculation.

start=0

[in] Initial index for calculation.

count=WHOLE_ARRAY

[in] The number of elements for calculation.

Return Value

Skewness of array elements. In case of error it returns [NaN](#) (not a number).

MathKurtosis

Calculates the kurtosis (fourth moment) of array elements. Analog of the [kurtosis\(\)](#) in R (e1071 library).

```
double MathKurtosis(  
    const double& array[],           // array with data  
    const int     start=0,           // initial index  
    const int     count=WHOLE_ARRAY // the number of elements  
);
```

Parameters

array

[in] Array with data for calculation.

start=0

[in] Initial index for calculation.

count=WHOLE_ARRAY

[in] The number of elements for calculation.

Return Value

Kurtosis of array elements. In case of error it returns [NaN](#) (not a number).

Disclaimer

Calculation of the kurtosis is performed using the excess kurtosis around the normal distribution (excess kurtosis=kurtosis-3), i.e. the excess kurtosis of a normal distribution is zero.

It is positive if the peak of the distribution around the expected value is sharp, and negative if the peak is flat.

MathMoments

Calculates the first 4 moments (mean, variance, skewness, kurtosis) of array elements.

```
double MathMoments(
    const double& array[],           // array with data
    double& mean,                    // mean (1st moment)
    double& variance,                // variance (2nd moment)
    double& skewness,                // skewness (3rd moment)
    double& kurtosis,                // kurtosis (4th moment)
    const int start=0,               // initial index
    const int count=WHOLE_ARRAY     // the number of elements
);
```

Parameters

array

[in] Array with data for calculation.

mean

[out] Variable for the mean (1st moment)

variance

[out] Variable for the variance (2nd moment)

skewness

[out] Variable for the skewness (3rd moment)

kurtosis

[out] Variable for the kurtosis (4th moment)

start=0

[in] Initial index for calculation.

count=WHOLE_ARRAY

[in] The number of elements for calculation.

Return Value

Returns true if the moments have been calculated successfully, otherwise false.

Disclaimer

Calculation of the kurtosis is performed using the excess kurtosis around the normal distribution (excess kurtosis=kurtosis-3), i.e. the excess kurtosis of a normal distribution is zero.

It is positive if the peak of the distribution around the expected value is sharp, and negative if the peak is flat.

MathMedian

Calculates the median value of array elements. Analog of the [median\(\)](#) in R.

```
double MathMedian(  
    const double& array[],           // array with data  
    const int     start=0,           // initial index  
    const int     count=WHOLE_ARRAY // the number of elements  
);
```

Parameters

array

[in] Array with data for calculation.

start=0

[in] Initial index for calculation.

count=WHOLE_ARRAY

[in] The number of elements for calculation.

Return Value

The median value of array elements. In case of error it returns [NaN](#) (not a number).

MathStandardDeviation

Calculates the standard deviation of array elements. Analog of the [sd\(\)](#) in R.

```
double MathStandardDeviation(  
    const double& array[],           // array with data  
    const int     start=0,           // initial index  
    const int     count=WHOLE_ARRAY // the number of elements  
);
```

Parameters

array

[in] Array with data for calculation.

start=0

[in] Initial index for calculation.

count=WHOLE_ARRAY

[in] The number of elements for calculation.

Return Value

The standard deviation of array elements. In case of error it returns [NaN](#) (not a number).

MathAverageDeviation

Calculates the average absolute deviation of array elements. Analog of the [aad\(\)](#) in R.

```
double MathAverageDeviation(  
    const double& array[],           // array with data  
    const int     start=0,           // initial index  
    const int     count=WHOLE_ARRAY // the number of elements  
);
```

Parameters

array

[in] Array with data for calculation.

start=0

[in] Initial index for calculation.

count=WHOLE_ARRAY

[in] The number of elements for calculation.

Return Value

The average absolute deviation of array elements. In case of error it returns [NaN](#) (not a number).

Normal Distribution

This section contains functions for working with normal distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the normal law. The distribution is defined by the following formula:

$$f_{Normal}(x|\mu,\sigma)=\frac{1}{\sigma\sqrt{2\pi}}e^{-\frac{(x-\mu)^2}{2\sigma^2}}$$

where:

- x — value of the random variable
- μ — expected value
- σ — root-mean-square deviation

In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityNormal	Calculates the probability density function of the normal distribution
MathCumulativeDistributionNormal	Calculates the value of the normal probability distribution function
MathQuantileNormal	Calculates the value of the inverse normal distribution function for the specified probability
MathRandomNormal	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the normal law

MathMomentsNormal

Calculates the theoretical numerical values of the first 4 moments of the normal distribution

Example:

```
#include <Graphics\Graphic.mqh>
#include <Math\Stat\Normal.mqh>
#include <Math\Stat\Math.mqh>
#property script_show_inputs
//--- input parameters
input double mean_value=0; // expected value (mean)
input double std_dev=1;    // root-mean-square deviation (standard deviation)
//+-----+
//| Script program start function |
//+-----+
void OnStart()
{
//--- hide the price chart
    ChartSetInteger(0,CHART_SHOW,false);
//--- initialize the random number generator
    MathSrand(GetTickCount());
//--- generate a sample of the random variable
    long chart=0;
    string name="GraphicNormal";
    int n=1000000; // the number of values in the sample
    int ncells=51; // the number of intervals in the histogram
    double x[]; // centers of the histogram intervals
    double y[]; // the number of values from the sample falling within the intervals
    double data[]; // sample of random values
    double max,min; // the maximum and minimum values in the sample
//--- obtain a sample from the normal distribution
    MathRandomNormal(mean_value,std_dev,n,data);
//--- calculate the data to plot the histogram
    CalculateHistogramArray(data,x,y,max,min,ncells);
//--- obtain the sequence boundaries and the step for plotting the theoretical curve
    double step;
    GetMaxMinStepValues(max,min,step);
    step=MathMin(step,(max-min)/ncells);
//--- obtain the theoretically calculated data at the interval of [min,max]
    double x2[];
    double y2[];
    MathSequence(min,max,step,x2);
    MathProbabilityDensityNormal(x2,mean_value,std_dev,false,y2);
//--- set the scale
    double theor_max=y2[ArrayMaximum(y2)];
    double sample_max=y[ArrayMaximum(y)];
    double k=sample_max/theor_max;
    for(int i=0; i<ncells; i++)
```

```

        y[i]/=k;
//--- output charts
        CGraphic graphic;
        if(ObjectFind(chart,name)<0)
            graphic.Create(chart,name,0,0,0,780,380);
        else
            graphic.Attach(chart,name);
        graphic.BackgroundMain(StringFormat("Normal distribution mu=%G sigma=%G",mean_value,

    ArrayResize(intervals,cells);
    ArrayResize(frequency,cells);
//--- define the interval centers
    for(int i=0; i<cells; i++)
    {
        intervals[i]=minv+(i+0.5)*width;
        frequency[i]=0;
    }
//--- fill the frequencies of falling within the interval
    for(int i=0; i<size; i++)
    {
        int ind=int((data[i]-minv)/width);
        if(ind>=cells) ind=cells-1;
        frequency[ind]++;
    }
    return (true);
}
//+-----+

```

```
///| Calculates values for sequence generation |
///+-----+
void GetMaxMinStepValues(double &maxv, double &minv, double &stepv)
{
    ///--- calculate the absolute range of the sequence to obtain the precision of normalization
    double range=MathAbs(maxv-minv);
    int degree=(int)MathRound(MathLog10(range));
    ///--- normalize the maximum and minimum values to the specified precision
    maxv=NormalizeDouble(maxv, degree);
    minv=NormalizeDouble(minv, degree);
    ///--- sequence generation step is also set based on the specified precision
    stepv=NormalizeDouble(MathPow(10, -degree), degree);
    if((maxv-minv)/stepv<10)
        stepv/=10.;
}
```

MathProbabilityDensityNormal

Calculates the value of the probability density function of normal distribution with the mu and sigma parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathProbabilityDensityNormal(
    const double x,           // value of random variable
    const double mu,          // mean parameter of the distribution (expected value)
    const double sigma,       // sigma parameter of the distribution (root-mean-square deviation)
    const bool log_mode,      // calculate the logarithm of the value
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability density function of normal distribution with the mu and sigma parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathProbabilityDensityNormal(
    const double x,           // value of random variable
    const double mu,          // mean parameter of the distribution (expected value)
    const double sigma,       // sigma parameter of the distribution (root-mean-square deviation)
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability density function of normal distribution with the mu and sigma parameters for an array of random variables x[]. In case of error it returns false. Analog of the [dnorm\(\)](#) in R.

```
bool MathProbabilityDensityNormal(
    const double& x[],        // array with the values of random variable
    const double mu,          // mean parameter of the distribution (expected value)
    const double sigma,       // sigma parameter of the distribution (root-mean-square deviation)
    const bool log_mode,      // calculate the logarithm of the value
    double& result[]          // array for values of the probability density function
);
```

Calculates the value of the probability density function of normal distribution with the mu and sigma parameters for an array of random variables x[]. In case of error it returns false.

```
bool MathProbabilityDensityNormal(
    const double& x[],        // array with the values of random variable
    const double mu,          // mean parameter of the distribution (expected value)
    const double sigma,       // sigma parameter of the distribution (root-mean-square deviation)
    double& result[]          // array for values of the probability density function
);
```

Parameters

x
[in] Value of random variable.

x[]

[in] Array with the values of random variable.

mu

[in] mean parameter of the distribution (expected value).

sigma

[in] sigma parameter of the distribution (root-mean-square deviation).

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to get the error code.

result[]

[out] Array to obtain the values of the probability density function.

MathCumulativeDistributionNormal

Calculates the value of the normal distribution function with the mu and sigma parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionNormal(
    const double x,           // value of random variable
    const double mu,          // expected value
    const double sigma,       // root-mean-square deviation
    const bool tail,          // flag for calculation of tail
    const bool log_mode,      // calculate the logarithm of the value
    int& error_code           // variable to store the error code
);
```

Calculates the value of the normal distribution function with the mu and sigma parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionNormal(
    const double x,           // value of random variable
    const double mu,          // expected value
    const double sigma,       // root-mean-square deviation
    int& error_code           // variable to store the error code
);
```

Calculates the value of the normal distribution function with the mu and sigma parameters for an array of random variables x[]. In case of error it returns false. Analog of the [dnorm\(\)](#) in R.

```
bool MathCumulativeDistributionNormal(
    const double& x[],        // array with the values of random variable
    const double mu,          // expected value
    const double sigma,       // root-mean-square deviation
    const bool tail,          // flag for calculation of tail
    const bool log_mode,      // calculate the logarithm of the value
    double& result[]          // array for values of the probability function
);
```

Calculates the value of the normal distribution function with the mu and sigma parameters for an array of random variables x[]. In case of error it returns false.

```
bool MathCumulativeDistributionNormal(
    const double& x[],        // array with the values of random variable
    const double mu,          // expected value
    const double sigma,       // root-mean-square deviation
    double& result[]          // array for values of the probability function
);
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

mu

[in] mean parameter of the distribution (expected value).

sigma

[in] sigma parameter of the distribution (root-mean-square deviation).

tail

[in] Flag of calculation. If tail=true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to get the error code.

result[]

[out] Array to obtain the values of the probability function.

MathQuantileNormal

For the specified *probability*, the function calculates the value of inverse normal distribution function with the mu and sigma parameters. In case of error it returns [NaN](#).

```
double MathQuantileNormal(
    const double probability, // probability value of random variable
    const double mu,         // expected value
    const double sigma,      // root-mean-square deviation
    const bool tail,         // flag for calculation of tail
    const bool log_mode,     // calculate the logarithm of the value
    int& error_code          // variable to store the error code
);
```

For the specified *probability*, the function calculates the value of inverse normal distribution function with the mu and sigma parameters. In case of error it returns [NaN](#).

```
double MathQuantileNormal(
    const double probability, // probability value of random variable
    const double mu,         // expected value
    const double sigma,      // root-mean-square deviation
    int& error_code          // variable to store the error code
);
```

For the specified *probability[]* array of probability values, the function calculates the values of inverse normal distribution function with the mu and sigma parameters. In case of error it returns false. Analog of the [gnorm\(\)](#) in R.

```
bool MathQuantileNormal(
    const double& probability[], // array with probability values of random variable
    const double mu,            // expected value
    const double sigma,         // root-mean-square deviation
    const bool tail,            // flag for calculation of tail
    const bool log_mode,        // calculate the logarithm of the value
    double& result[]            // array with values of quantiles
);
```

For the specified *probability[]* array of probability values, the function calculates the values of inverse normal distribution function with the mu and sigma parameters. In case of error it returns false.

```
bool MathQuantileNormal(
    const double& probability[], // array with probability values of random variable
    const double mu,            // expected value
    const double sigma,         // root-mean-square deviation
    double& result[]            // array with values of quantiles
);
```

Parameters

probability

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

mu

[in] mean parameter of the distribution (expected value).

sigma

[in] sigma parameter of the distribution (root-mean-square deviation).

tail

[in] Flag of calculation. If false, then calculation is performed for 1.0 - probability.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to get the error code.

result[]

[out] Array to obtain the quantiles.

MathRandomNormal

Generates a pseudorandom variable distributed according to the normal law with the mu and sigma parameters. In case of error it returns [NaN](#).

```
double MathRandomNormal (
    const double mu,           // expected value
    const double sigma,       // root-mean-square deviation
    int& error_code            // variable to store the error code
);
```

Generates pseudorandom variables distributed according to the normal law with the mu and sigma parameters. In case of error it returns false. Analog of the [rnorm\(\)](#) in R.

```
bool MathRandomNormal (
    const double mu,           // expected value
    const double sigma,       // root-mean-square deviation
    const int data_count,     // amount of required data
    double& result[]          // array to obtain the pseudorandom variables
);
```

Parameters

mu

[in] mean parameter of the distribution (expected value).

sigma

[in] sigma parameter of the distribution (root-mean-square deviation).

data_count

[in] The number of pseudorandom variables to be obtained.

error_code

[out] Variable to get the error code.

result[]

[out] Array to obtain the values of pseudorandom variables.

MathMomentsNormal

Calculates the theoretical numerical values of the first 4 moments of the normal distribution.

```
double MathMomentsNormal(  
    const double mu,           // expected value  
    const double sigma,       // root-mean-square deviation  
    double& mean,             // variable for the mean  
    double& variance,         // variable for the variance  
    double& skewness,         // variable for the skewness  
    double& kurtosis,         // variable for the kurtosis  
    int& error_code           // variable to store the error code  
);
```

Parameters

mu

[in] mean parameter of the distribution (expected value).

sigma

[in] sigma parameter of the distribution (root-mean-square deviation).

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if the moments have been calculated successfully, otherwise false.

Log-normal distribution

This section contains functions for working with log-normal distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the log-normal law. The log-normal distribution is defined by the following formula:

$$f_{Lognormal}(x|\mu,\sigma) = \frac{1}{x\sigma\sqrt{2\pi}} e^{-\frac{(\ln(x)-\mu)^2}{2\sigma^2}}$$

where:

- x – value of the random variable
- μ – logarithm of the expected value
- σ – logarithm of the root-mean-square deviation

In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityLognormal	Calculates the probability density function of the log-normal distribution
MathCumulativeDistributionLognormal	Calculates the value of the log-normal probability distribution function
MathQuantileLognormal	Calculates the value of the inverse log-normal distribution function for the specified probability
MathRandomLognormal	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the log-normal law

MathMomentsLognormal

Calculates the theoretical numerical values of the first 4 moments of the log-normal distribution

Example:

```
#include <Graphics\Graphic.mqh>
#include <Math\Stat\Lognormal.mqh>
#include <Math\Stat\Math.mqh>
#property script_show_inputs
//--- input parameters
input double mean_value=1.0; // logarithm of the expected value (log mean)
input double std_dev=0.25; // logarithm of the root-mean-square deviation (log standard deviation)
//+-----+
//| Script program start function |
//+-----+
void OnStart()
{
//--- hide the price chart
ChartSetInteger(0,CHART_SHOW,false);
//--- initialize the random number generator
MathSrand(GetTickCount());
//--- generate a sample of the random variable
long chart=0;
string name="GraphicNormal";
int n=1000000; // the number of values in the sample
int ncells=51; // the number of intervals in the histogram
double x[]; // centers of the histogram intervals
double y[]; // the number of values from the sample falling within the intervals
double data[]; // sample of random values
double max,min; // the maximum and minimum values in the sample
//--- obtain a sample from the log-normal distribution
MathRandomLognormal(mean_value,std_dev,n,data);
//--- calculate the data to plot the histogram
CalculateHistogramArray(data,x,y,max,min,ncells);
//--- obtain the sequence boundaries and the step for plotting the theoretical curve
double step;
GetMaxMinStepValues(max,min,step);
step=MathMin(step,(max-min)/ncells);
//--- obtain the theoretically calculated data at the interval of [min,max]
double x2[];
double y2[];
MathSequence(min,max,step,x2);
MathProbabilityDensityLognormal(x2,mean_value,std_dev,false,y2);
//--- set the scale
double theor_max=y2[ArrayMaximum(y2)];
double sample_max=y[ArrayMaximum(y)];
double k=sample_max/theor_max;
```

```

    for(int i=0; i<ncells; i++)
        y[i]/=k;
//--- output charts
CGraphic graphic;
if(ObjectFind(chart,name)<0)
    graphic.Create(chart,name,0,0,0,780,380);
else
    graphic.Attach(chart,name);
graphic.BackgroundMain(StringFormat("Lognormal distribution mu=%G sigma=%G",mean_va
graphic.BackgroundMainSize(16);
//--- disable automatic scaling of the Y axis
graphic.YAxis().AutoScale(false);
graphic.YAxis().Max(theor_max);
graphic.YAxis().Min(0);
//--- plot all curves
graphic.CurveAdd(x,y,CURVE_HISTOGRAM,"Sample").HistogramWidth(6);
//--- and now plot the theoretical curve of the distribution density
graphic.CurveAdd(x2,y2,CURVE_LINES,"Theory");
graphic.CurvePlotAll();
//--- plot all curves
graphic.Update();
}
//+-----+
//| Calculate frequencies for data set |
//+-----+
bool CalculateHistogramArray(const double &data[],double &intervals[],double &frequency
    double &maxv,double &minv,const int cells=10)
{
    if(cells<=1) return (false);

    maxv=NormalizeDouble(maxv, degree);
    minv=NormalizeDouble(minv, degree);
    //-- sequence generation step is also set based on the specified precision
    stepv=NormalizeDouble(MathPow(10, -degree), degree);
    if ((maxv-minv)/stepv<10)
        stepv/=10.;
}
```

MathProbabilityDensityLognormal

Calculates the value of the probability density function of log-normal distribution with the mu and sigma parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathProbabilityDensityLognormal(
    const double x,           // value of random variable
    const double mu,          // logarithm of the expected value (log mean)
    const double sigma,       // logarithm of the root-mean-square deviation (log s
    const bool log_mode,      // calculate the logarithm of the value, if log_mode=
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability density function of log-normal distribution with the mu and sigma parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathProbabilityDensityLognormal(
    const double x,           // value of random variable
    const double mu,          // logarithm of the expected value (log mean)
    const double sigma,       // logarithm of the root-mean-square deviation (log s
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability density function of log-normal distribution with the mu and sigma parameters for an array of random variables x[]. In case of error it returns [NaN](#). Analog of the [dlnorm\(\)](#) in R.

```
bool MathProbabilityDensityLognormal(
    const double& x[],        // array with the values of random variable
    const double mu,          // logarithm of the expected value (log mean)
    const double sigma,       // logarithm of the root-mean-square deviation (log
    const bool log_mode,      // calculate the logarithm of the value, if log_mode
    double& result[]          // array for values of the probability density funct
);
```

Calculates the value of the probability density function of log-normal distribution with the mu and sigma parameters for an array of random variables x[]. In case of error it returns false.

```
bool MathProbabilityDensityLognormal(
    const double& x[],        // array with the values of random variable
    const double mu,          // logarithm of the expected value (log mean)
    const double sigma,       // logarithm of the root-mean-square deviation (log
    double& result[]          // array for values of the probability density funct
);
```

Parameters

x
[in] Value of random variable.

x[]

[in] Array with the values of random variable.

mu

[in] Logarithm of the expected value (log_mean).

sigma

[in] Logarithm of the root-mean-square deviation (log standard deviation).

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array to obtain the values of the probability density function.

MathCumulativeDistributionLognormal

Calculates the log-normal distribution function of probabilities with the mu and sigma parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionLognormal(
    const double x,           // value of random variable
    const double mu,          // logarithm of the expected value (log mean)
    const double sigma,       // logarithm of the root-mean-square deviation (log s
    const bool tail,          // flag of calculation, if true, then the probability
    const bool log_mode,      // calculate the logarithm of the value, if log_mode=
    int& error_code           // variable to store the error code
);
```

Calculates the log-normal distribution function of probabilities with the mu and sigma parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionLognormal(
    const double x,           // value of random variable
    const double mu,          // logarithm of the expected value (log mean)
    const double sigma,       // logarithm of the root-mean-square deviation (log s
    int& error_code           // variable to store the error code
);
```

Calculates the log-normal distribution function of probabilities with the mu and sigma parameters for an array of random variables x[]. In case of error it returns false. Analog of the [plnorm\(\)](#) in R.

```
bool MathCumulativeDistributionLognormal(
    const double& x[],        // array with the values of random variable
    const double mu,          // logarithm of the expected value (log mean)
    const double sigma,       // logarithm of the root-mean-square deviation (log
    const bool tail,          // flag of calculation, if true, then the probability
    const bool log_mode,      // flag to calculate the logarithm of the value, if
    double& result[]          // array for values of the probability function
);
```

Calculates the log-normal distribution function of probabilities with the mu and sigma parameters for an array of random variables x[]. In case of error it returns false.

```
bool MathCumulativeDistributionLognormal(
    const double& x[],        // array with the values of random variable
    const double mu,          // logarithm of the expected value (log mean)
    const double sigma,       // logarithm of the root-mean-square deviation (log
    double& result[]          // array for values of the probability function
);
```

Parameters

x
[in] Value of random variable.

x[]

[in] Array with the values of random variable.

mu

[in] Logarithm of the expected value (log_mean).

sigma

[in] Logarithm of the root-mean-square deviation (log standard deviation).

tail

[in] Flag of calculation, if true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array to obtain the values of the probability function.

MathQuantileLognormal

For the specified probability, the function calculates the value of inverse log-normal distribution function with the mu and sigma parameters. In case of error it returns [NaN](#).

```
double MathQuantileLognormal(
    const double probability, // probability value of random variable occurrence
    const double mu,         // logarithm of the expected value (log mean)
    const double sigma,      // logarithm of the root-mean-square deviation (log s
    const bool tail,         // flag of calculation, if false, then calculation is
    const bool log_mode,     // flag of calculation, if log_mode=true, calculation
    int& error_code          // variable to store the error code
);
```

For the specified probability, the function calculates the value of inverse log-normal distribution function with the mu and sigma parameters. In case of error it returns [NaN](#).

```
double MathQuantileLognormal(
    const double probability, // probability value of random variable occurrence
    const double mu,         // logarithm of the expected value (log mean)
    const double sigma,      // logarithm of the root-mean-square deviation (log s
    int& error_code          // variable to store the error code
);
```

For the specified probability[] array of probability values, the function calculates the value of inverse log-normal distribution function with the mu and sigma parameters. In case of error it returns false. Analog of the [qlnorm\(\)](#) in R.

```
bool MathQuantileLognormal(
    const double& probability[], // array with probability values of random variable
    const double mu,            // logarithm of the expected value (log mean)
    const double sigma,         // logarithm of the root-mean-square deviation (log
    const bool tail,            // flag of calculation, if false, then calculation :
    const bool log_mode,        // flag of calculation, if log_mode=true, calculatio
    double& result[]            // array with values of quantiles
);
```

For the specified probability[] array of probability values, the function calculates the value of inverse log-normal distribution function with the mu and sigma parameters. In case of error it returns false.

```
bool MathQuantileLognormal(
    const double& probability[], // array with probability values of random variable
    const double mu,            // logarithm of the expected value (log mean)
    const double sigma,         // logarithm of the root-mean-square deviation (log
    double& result[]            // array with values of quantiles
);
```

Parameters

probability

[in] Probability value of random variable occurrence.

probability[]

[in] Array with probability values of random variable.

mu

[in] Logarithm of the expected value (log_mean).

sigma

[in] Logarithm of the root-mean-square deviation (log standard deviation).

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to store the error code.

result[]

[out] Array with values of quantiles.

MathRandomLognormal

Generates a pseudorandom variable distributed according to the log-normal law with the mu sigma parameters. In case of error it returns [NaN](#).

```
double MathRandomLognormal (
    const double mu,           // logarithm of the expected value (log mean)
    const double sigma,       // logarithm of the root-mean-square deviation (log s
    int& error_code           // variable to store the error code
);
```

Generates pseudorandom variables distributed according to the log-normal law with the mu sigma parameters. In case of error it returns false. Analog of the [rlnorm\(\)](#) in R.

```
double MathRandomLognormal (
    const double mu,           // logarithm of the expected value (log mean)
    const double sigma,       // logarithm of the root-mean-square deviation (log s
    const int data_count,     // amount of required data
    double& result[]          // array with values of pseudorandom variables
);
```

Parameters

mu

[in] Logarithm of the expected value (log_mean).

sigma

[in] Logarithm of the root-mean-square deviation (log standard deviation).

data_count

[in] Amount of required data.

error_code

[out] Variable to store the error code.

result[]

[out] Array with values of pseudorandom variables.

MathMomentsLognormal

Calculates the theoretical numerical values of the first 4 moments of the log-normal distribution. Returns true if calculation of the moments has been successful, otherwise false.

```
double MathMomentsLognormal(  
    const double mu,           // logarithm of the expected value (log mean)  
    const double sigma,        // logarithm of the root-mean-square deviation (log s  
    double& mean,              // variable for the mean  
    double& variance,          // variable for the variance  
    double& skewness,          // variable for the skewness  
    double& kurtosis,          // variable for the kurtosis  
    int& error_code            // variable to store the error code  
);
```

Parameters

mu

[in] Logarithm of the expected value (log_mean).

sigma

[in] Logarithm of the root-mean-square deviation (log standard deviation).

mean

[in] Variable for the mean.

variance

[out] Variable for the variance.

skewness

[out] Variable for the skewness.

kurtosis

[out] Variable for the kurtosis.

error code

[out] Variable to store the error code.

Return Value

Returns true if the moments have been calculated successfully, otherwise false.

Beta distribution

This section contains functions for working with beta distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the corresponding law. The beta distribution is defined by the following formula:

$$f_{Beta}(x|a,b) = \frac{1}{B(a,b)} x^{a-1} (1-x)^{b-1}$$

where:

- x – value of the random variable
- a – the first parameter of beta distribution
- b – the second parameter of beta distribution

In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityBeta	Calculates the probability density function of the beta distribution
MathCumulativeDistributionBeta	Calculates the value of the beta probability distribution function
MathQuantileBeta	Calculates the value of the inverse beta distribution function for the specified probability
MathRandomBeta	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the beta distribution law

MathMomentsBeta

Calculates the theoretical numerical values of the first 4 moments of the beta distribution

Example:

```
#include <Graphics\Graphic.mqh>
#include <Math\Stat\Beta.mqh>
#include <Math\Stat\Math.mqh>
#property script_show_inputs
//--- input parameters
input double alpha=2;    // the first parameter of beta distribution (shape1)
input double beta=5;     // the second parameter of beta distribution (shape2)
//+-----+
//| Script program start function |
//+-----+
void OnStart()
{
    //--- hide the price chart
    ChartSetInteger(0,CHART_SHOW,false);
    //--- initialize the random number generator
    MathSrand(GetTickCount());
    //--- generate a sample of the random variable
    long chart=0;
    string name="GraphicNormal";
    int n=1000000;        // the number of values in the sample
    int ncells=51;        // the number of intervals in the histogram
    double x[];           // centers of the histogram intervals
    double y[];           // the number of values from the sample falling within the intervals
    double data[];        // sample of random values
    double max,min;       // the maximum and minimum values in the sample
    //--- obtain a sample from the beta distribution
    MathRandomBeta(alpha,beta,n,data);
    //--- calculate the data to plot the histogram
    CalculateHistogramArray(data,x,y,max,min,ncells);
    //--- obtain the sequence boundaries and the step for plotting the theoretical curve
    double step;
    GetMaxMinStepValues(max,min,step);
    step=MathMin(step,(max-min)/ncells);
    //--- obtain the theoretically calculated data at the interval of [min,max]
    double x2[];
    double y2[];
    MathSequence(min,max,step,x2);
    MathProbabilityDensityBeta(x2,alpha,beta,false,y2);
    //--- set the scale
    double theor_max=y2[ArrayMaximum(y2)];
    double sample_max=y[ArrayMaximum(y)];
    double k=sample_max/theor_max;
    for(int i=0; i<ncells; i++)
```

```

        y[i]/=k;
//--- output charts
        CGraphic graphic;
        if(ObjectFind(chart,name)<0)
            graphic.Create(chart,name,0,0,0,780,380);
        else
            graphic.Attach(chart,name);
        graphic.BackgroundMain(StringFormat("Beta distribution alpha=%G beta=%G",alpha,beta));

    double width=range/cells;
    if(width==0) return false;
    ArrayResize(intervals,cells);
    ArrayResize(frequency,cells);
//--- define the interval centers
    for(int i=0; i<cells; i++)
    {
        intervals[i]=minv+(i+0.5)*width;
        frequency[i]=0;
    }
//--- fill the frequencies of falling within the interval
    for(int i=0; i<size; i++)
    {
        int ind=int((data[i]-minv)/width);
        if(ind>=cells) ind=cells-1;
        frequency[ind]++;
    }
    return (true);
}
//+-----+

```

```
///| Calculates values for sequence generation |
//+-----+
void GetMaxMinStepValues(double &maxv, double &minv, double &stepv)
{
//--- calculate the absolute range of the sequence to obtain the precision of normalization
    double range=MathAbs(maxv-minv);
    int degree=(int)MathRound(MathLog10(range));
//--- normalize the maximum and minimum values to the specified precision
    maxv=NormalizeDouble(maxv, degree);
    minv=NormalizeDouble(minv, degree);
//--- sequence generation step is also set based on the specified precision
    stepv=NormalizeDouble(MathPow(10, -degree), degree);
    if((maxv-minv)/stepv<10)
        stepv/=10.;
}
```

MathProbabilityDensityBeta

Calculates the value of the probability density function of beta distribution with the a and b parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathProbabilityDensityBeta(
    const double x,           // value of random variable
    const double a,           // the first parameter of beta distribution (shape1)
    const double b,           // the second parameter of beta distribution (shape2)
    const bool log_mode,      // calculate the logarithm of the value, if log_mode=true
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability density function of beta distribution with the a and b parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathProbabilityDensityBeta(
    const double x,           // value of random variable
    const double a,           // the first parameter of beta distribution (shape1)
    const double b,           // the second parameter of beta distribution (shape2)
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability density function of beta distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false. Analog of the [dbeta\(\)](#) in R.

```
bool MathProbabilityDensityBeta(
    const double& x[],        // array with the values of random variable
    const double a,           // the first parameter of beta distribution (shape1)
    const double b,           // the second parameter of beta distribution (shape2)
    const bool log_mode,      // flag to calculate the logarithm of the value, if log_mode=true
    double& result[]         // array for values of the probability density function
);
```

Calculates the value of the probability density function of beta distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false.

```
bool MathProbabilityDensityBeta(
    const double& x[],        // array with the values of random variable
    const double a,           // the first parameter of beta distribution (shape1)
    const double b,           // the second parameter of beta distribution (shape2)
    double& result[]         // array for values of the probability density function
);
```

Parameters

x
[in] Value of random variable.

x[]

[in] Array with the values of random variable.

a

[in] The first parameter of beta distribution (shape 1).

b

[in] The second parameter of beta distribution (shape 2)

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

MathCumulativeDistributionBeta

Calculates the probability distribution function of beta distribution with the a and b parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionBeta(
    const double x,           // value of random variable
    const double a,           // the first parameter of beta distribution (shape1)
    const double b,           // the second parameter of beta distribution (shape2)
    const bool tail,          // flag of calculation, if true, then the probability
    const bool log_mode,      // calculate the logarithm of the value, if log_mode=
    int& error_code           // variable to store the error code
);
```

Calculates the probability distribution function of beta distribution with the a and b parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionBeta(
    const double x,           // value of random variable
    const double a,           // the first parameter of beta distribution (shape1)
    const double b,           // the second parameter of beta distribution (shape2)
    int& error_code           // variable to store the error code
);
```

Calculates the probability distribution function of beta distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false. Analog of the [pbeta\(\)](#) in R.

```
bool MathCumulativeDistributionBeta(
    const double& x[],        // array with the values of random variable
    const double a,           // the first parameter of beta distribution (shape1)
    const double b,           // the second parameter of beta distribution (shape2)
    const bool tail,          // flag of calculation, if true, then the probability
    const bool log_mode,      // flag to calculate the logarithm of the value, if
    double& result[]          // array for values of the probability function
);
```

Calculates the probability distribution function of beta distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false.

```
bool MathCumulativeDistributionBeta(
    const double& x[],        // array with the values of random variable
    const double a,           // the first parameter of beta distribution (shape1)
    const double b,           // the second parameter of beta distribution (shape2)
    double& result[]          // array for values of the probability function
);
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

a

[in] The first parameter of beta distribution (shape 1).

b

[in] The second parameter of beta distribution (shape 2)

tail

[in] Flag of calculation, if true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

MathQuantileBeta

For the specified *probability*, the function calculates the value of inverse beta distribution function with the a and b parameters. In case of error it returns [NaN](#).

```
double MathQuantileBeta(
    const double probability, // probability value of random variable occurrence
    const double a,          // the first parameter of beta distribution (shape1)
    const double b,          // the second parameter of beta distribution (shape2)
    const bool tail,         // flag of calculation, if false, then calculation is
    const bool log_mode,     // flag of calculation, if log_mode=true, calculation
    int& error_code          // variable to store the error code
);
```

For the specified *probability*, the function calculates the value of inverse beta distribution function with the a and b parameters. In case of error it returns [NaN](#).

```
double MathQuantileBeta(
    const double probability, // probability value of random variable occurrence
    const double a,          // the first parameter of beta distribution (shape1)
    const double b,          // the second parameter of beta distribution (shape2)
    int& error_code          // variable to store the error code
);
```

For the specified *probability[]* array of probability values, the function calculates the values of inverse beta distribution function with the a and b parameters. In case of error it returns false. Analog of the [qbeta\(\)](#) in R.

```
double MathQuantileBeta(
    const double& probability[], // array with probability values of random variable
    const double a,             // the first parameter of beta distribution (shape1)
    const double b,             // the second parameter of beta distribution (shape2)
    const bool tail,            // flag of calculation, if false, then calculation is
    const bool log_mode,        // flag of calculation, if log_mode=true, calculation
    double& result[]            // array with values of quantiles
);
```

For the specified *probability[]* array of probability values, the function calculates the values of inverse beta distribution function with the a and b parameters. In case of error it returns false.

```
bool MathQuantileBeta(
    const double& probability[], // array with probability values of random variable
    const double a,             // the first parameter of beta distribution (shape1)
    const double b,             // the second parameter of beta distribution (shape2)
    double& result[]            // array with values of quantiles
);
```

Parameters

probability

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

a

[in] The first parameter of beta distribution (shape1).

b

[in] The second parameter of beta distribution (shape2).

tail

[in] Flag of calculation, if lower_tail=false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

MathRandomBeta

Generates a pseudorandom variable distributed according to the law of beta distribution with the *a* and *b* parameters. In case of error it returns [NaN](#).

```
double MathRandomBeta(  
    const double a,           // the first parameter of beta distribution (shape1)  
    const double b,           // the second parameter of beta distribution (shape2)  
    int& error_code           // variable to store the error code  
);
```

Generates pseudorandom variables distributed according to the law of beta distribution with the *a* and *b* parameters. In case of error it returns false. Analog of the [rbeta\(\)](#) in R.

```
bool MathRandomBeta(  
    const double a,           // the first parameter of beta distribution (shape1)  
    const double b,           // the second parameter of beta distribution (shape2)  
    const int data_count,     // amount of required data  
    double& result[]          // array to obtain the pseudorandom variables  
);
```

Parameters

a

[in] The first parameter of beta distribution (shape1)

b

[in] The second parameter of beta distribution (shape2).

data_count

[in] The number of pseudorandom variables to be obtained.

error_code

[out] Variable to store the error code.

result[]

[out] Array to obtain the values of pseudorandom variables.

MathMomentsBeta

Calculates the theoretical numerical values of the first 4 moments of the beta distribution.

```
double MathMomentsBeta(  
    const double a,           // the first parameter of beta distribution (shape1)  
    const double b,           // the second parameter of beta distribution (shape2)  
    double& mean,             // variable for the mean  
    double& variance,         // variable for the variance  
    double& skewness,         // variable for the skewness  
    double& kurtosis,         // variable for the kurtosis  
    int& error_code           // variable for the error code  
);
```

Parameters

a

[in] The first parameter of beta distribution (shape1).

b

[in] The second parameter of beta distribution (shape2).

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if the moments have been calculated successfully, otherwise false.

Noncentral beta distribution

This section contains functions for working with noncentral beta distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the corresponding law. The noncentral beta distribution is defined by the following formula:

$$f_{\text{NoncentralBeta}}(x|a,b,\lambda) = \sum_{r=0}^{\infty} e^{-\frac{\lambda}{2}} \frac{\left(\frac{\lambda}{2}\right)^r}{r!} \frac{x^{a+r-1}(1-x)^{b-1}}{B(a+r,b)}$$

where:

- x — value of the random variable
- a — the first parameter of beta distribution
- b — the second parameter of beta distribution
- λ — noncentrality parameter

In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
<u>MathProbabilityDensityNoncentralBeta</u>	Calculates the probability density function of the noncentral beta distribution
<u>MathCumulativeDistributionNoncentralBeta</u>	Calculates the value of the noncentral beta probability distribution function
<u>MathQuantileNoncentralBeta</u>	Calculates the value of the inverse noncentral beta distribution function for the specified probability
<u>MathRandomNoncentralBeta</u>	Generates a pseudorandom variable/array of pseudorandom variables distributed according

	to the noncentral beta distribution law
<u>MathMomentsNoncentralBeta</u>	Calculates the theoretical numerical values of the first 4 moments of the noncentral beta distribution

Example:

```

#include <Graphics\Graphic.mqh>
#include <Math\Stat\NoncentralBeta.mqh>
#include <Math\Stat\Math.mqh>
#property script_show_inputs
//--- input parameters
input double a_par=2;    // the first parameter of beta distribution (shape1)

}
```

MathProbabilityDensityNoncentralBeta

Calculates the value of the probability density function of noncentral beta distribution with the a, b and lambda parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathProbabilityDensityNoncentralBeta(
    const double x,           // value of random variable
    const double a,           // the first parameter of beta distribution (shape1)
    const double b,           // the second parameter of beta distribution (shape2)
    const double lambda,      // noncentrality parameter
    const bool log_mode,      // calculate the logarithm of the value, if log_mode=true
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability density function of noncentral beta distribution with the a, b and lambda parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathProbabilityDensityNoncentralBeta(
    const double x,           // value of random variable
    const double a,           // the first parameter of beta distribution (shape1)
    const double b,           // the second parameter of beta distribution (shape2)
    const double lambda,      // noncentrality parameter
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability density function of noncentral beta distribution with the a, b and lambda parameters for an array of random variables x[]. In case of error it returns false. Analog of the [dbeta\(\)](#) in R.

```
bool MathProbabilityDensityNoncentralBeta(
    const double& x[],        // array with the values of random variable
    const double a,           // the first parameter of beta distribution (shape1)
    const double b,           // the second parameter of beta distribution (shape2)
    const double lambda,      // noncentrality parameter
    const bool log_mode,      // flag to calculate the logarithm of the value, if log_mode=true
    double& result[]         // array for values of the probability density function
);
```

Calculates the value of the probability density function of noncentral beta distribution with the a, b and lambda parameters for an array of random variables x[]. In case of error it returns false.

```
bool MathProbabilityDensityNoncentralBeta(
    const double& x[],        // array with the values of random variable
    const double a,           // the first parameter of beta distribution (shape1)
    const double b,           // the second parameter of beta distribution (shape2)
    const double lambda,      // noncentrality parameter
    double& result[]         // array for values of the probability density function
);
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

a

[in] The first parameter of beta distribution (shape 1).

b

[in] The second parameter of beta distribution (shape 2)

lambda

[in] Noncentrality parameter

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

MathCumulativeDistributionNoncentralBeta

Calculates the probability distribution function of noncentral beta distribution with the a, b and lambda parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionNoncentralBeta(
    const double x,           // value of random variable
    const double a,           // the first parameter of beta distribution (shape1)
    const double b,           // the second parameter of beta distribution (shape2)
    const double lambda,      // noncentrality parameter
    const bool tail,          // flag of calculation, if true, then the probability
    const bool log_mode,      // calculate the logarithm of the value, if log_mode=
    int& error_code           // variable to store the error code
);
```

Calculates the probability distribution function of noncentral beta distribution with the a, b and lambda parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionNoncentralBeta(
    const double x,           // value of random variable
    const double a,           // the first parameter of beta distribution (shape1)
    const double b,           // the second parameter of beta distribution (shape2)
    const double lambda,      // noncentrality parameter
    int& error_code           // variable to store the error code
);
```

Calculates the probability distribution function of noncentral beta distribution with the a, b and lambda parameters for an array of random variables x[]. In case of error it returns false. Analog of the [pbeta\(\)](#) in R.

```
bool MathCumulativeDistributionNoncentralBeta(
    const double& x[],        // array with the values of random variable
    const double a,           // the first parameter of beta distribution (shape1)
    const double b,           // the second parameter of beta distribution (shape2)
    const double lambda,      // noncentrality parameter
    const bool tail,          // flag of calculation, if true, then the probability
    const bool log_mode,      // flag to calculate the logarithm of the value, if
    double& result[]          // array for values of the probability function
);
```

Calculates the probability distribution function of noncentral beta distribution with the a, b and lambda parameters for an array of random variables x[]. In case of error it returns false.

```
bool MathCumulativeDistributionNoncentralBeta(
    const double& x[],        // array with the values of random variable
    const double a,           // the first parameter of beta distribution (shape1)
    const double b,           // the second parameter of beta distribution (shape2)
    const double lambda,      // noncentrality parameter
    double& result[]          // array for values of the probability function
);
```

Parameters*x*

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

a

[in] The first parameter of beta distribution (shape 1).

b

[in] The second parameter of beta distribution (shape 2)

lambda

[in] Noncentrality parameter

tail

[in] Flag of calculation. If true, then the probability of random variable not exceeding *x* is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If *log_mode*=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

MathQuantileNoncentralBeta

Calculates the value of the inverse probability distribution function of noncentral beta distribution with the *a*, *b* and *lambda* parameters for the occurrence probability of a random variable *probability*. In case of error it returns [NaN](#).

```
double MathQuantileNoncentralBeta(
    const double probability, // probability value of random variable occurrence
    const double a,          // the first parameter of beta distribution (shape1)
    const double b,          // the second parameter of beta distribution (shape2)
    const double lambda,     // noncentrality parameter
    const bool tail,         // flag of calculation, if false, then calculation is
    const bool log_mode,     // flag of calculation, if log_mode=true, calculation
    int& error_code          // variable to store the error code
);
```

Calculates the value of the inverse probability distribution function of noncentral beta distribution with the *a*, *b* and *lambda* parameters for the occurrence probability of a random variable *probability*. In case of error it returns [NaN](#).

```
double MathQuantileNoncentralBeta(
    const double probability, // probability value of random variable occurrence
    const double a,          // the first parameter of beta distribution (shape1)
    const double b,          // the second parameter of beta distribution (shape2)
    const double lambda,     // noncentrality parameter
    int& error_code          // variable to store the error code
);
```

For the specified *probability[]* array of probability values, the function calculates the value of the inverse probability distribution function of noncentral beta distribution with the *a*, *b* and *lambda* parameters. In case of error it returns false. Analog of the [qbeta\(\)](#) in R.

```
double MathQuantileNoncentralBeta(
    const double& probability[], // array with probability values of random variable
    const double a,             // the first parameter of beta distribution (shape1)
    const double b,             // the second parameter of beta distribution (shape2)
    const double lambda,        // noncentrality parameter
    const bool tail,            // flag of calculation, if false, then calculation is
    const bool log_mode,        // flag of calculation, if log_mode=true, calculation
    double& result[]            // array with values of quantiles
);
```

For the specified *probability[]* array of probability values, the function calculates the value of the inverse probability distribution function of noncentral beta distribution with the *a*, *b* and *lambda* parameters. In case of error it returns false.

```
bool MathQuantileNoncentralBeta(
    const double& probability[], // array with probability values of random variable
    const double a,             // the first parameter of beta distribution (shape1)
    const double b,             // the second parameter of beta distribution (shape2)
```

```
const double  lambda,           // noncentrality parameter
double&       result[]         // array with values of quantiles
);
```

Parameters

probability

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

a

[in] The first parameter of beta distribution (shape1).

b

[in] The second parameter of beta distribution (shape2).

lambda

[in] Noncentrality parameter.

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

MathRandomNoncentralBeta

Generates a pseudorandom variable distributed according to the law of noncentral beta distribution the *a*, *b* and *lambda* parameters. In case of error it returns [NaN](#).

```
double MathRandomNoncentralBeta (
    const double a,           // the first parameter of beta distribution (shape1)
    const double b,           // the second parameter of beta distribution (shape2)
    const double lambda,      // noncentrality parameter
    int& error_code           // variable to store the error code
);
```

Generates pseudorandom variables distributed according to the law of noncentral beta distribution the *a*, *b* and *lambda* parameters. In case of error it returns false. Analog of the [rbeta\(\)](#) in R.

```
bool MathRandomNoncentralBeta (
    const double a,           // the first parameter of beta distribution (shape1)
    const double b,           // the second parameter of beta distribution (shape2)
    const double lambda,      // noncentrality parameter
    const int data_count,     // amount of required data
    double& result[]         // array to obtain the pseudorandom variables
);
```

Parameters

a

[in] The first parameter of beta distribution (shape1)

b

[in] The second parameter of beta distribution (shape2).

lambda

[in] Noncentrality parameter

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

MathMomentsNoncentralBeta

Calculates the theoretical numerical values of the first 4 moments of the noncentral beta distribution with the *a*, *b* and *lambda* parameters.

```
double MathMomentsNoncentralBeta(  
    const double a,           // the first parameter of beta distribution (shape1)  
    const double b,           // the second parameter of beta distribution (shape2)  
    const double lambda,      // noncentrality parameter  
    double& mean,             // variable for the mean  
    double& variance,         // variable for the variance  
    double& skewness,         // variable for the skewness  
    double& kurtosis,         // variable for the kurtosis  
    int& error_code           // variable for the error code  
);
```

Parameters

a

[in] The first parameter of beta distribution (shape1).

b

[in] The second parameter of beta distribution (shape2).

lambda

[in] Noncentrality parameter

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

Gamma distribution

This section contains functions for working with gamma distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the corresponding law. The gamma distribution is defined by the following formula:

$$f_{Gamma}(x|a,b) = \frac{1}{b^a \Gamma(a)} x^{a-1} e^{-\frac{x}{b}}$$

where:

- x – value of the random variable
- a – the first parameter of distribution
- b – the second parameter of distribution

In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityGamma	Calculates the probability density function of the gamma distribution
MathCumulativeDistributionGamma	Calculates the value of the gamma probability distribution function
MathQuantileGamma	Calculates the value of the inverse gamma distribution function for the specified probability
MathRandomGamma	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the gamma distribution law

MathMomentsGamma

Calculates the theoretical numerical values of the first 4 moments of the gamma distribution

Example:

```
#include <Graphics\Graphic.mqh>
#include <Math\Stat\Gamma.mqh>
#include <Math\Stat\Math.mqh>
#property script_show_inputs
//--- input parameters
input double alpha=9;    // the first parameter of distribution (shape)
input double beta=0.5;   // the second parameter of distribution (scale)
//+-----+
//| Script program start function |
//+-----+
void OnStart()
{
    //--- hide the price chart
    ChartSetInteger(0,CHART_SHOW,false);
    //--- initialize the random number generator
    MathSrand(GetTickCount());
    //--- generate a sample of the random variable
    long chart=0;
    string name="GraphicNormal";
    int n=1000000;        // the number of values in the sample
    int ncells=51;        // the number of intervals in the histogram
    double x[];           // centers of the histogram intervals
    double y[];           // the number of values from the sample falling within the intervals
    double data[];        // sample of random values
    double max,min;       // the maximum and minimum values in the sample
    //--- obtain a sample from the gamma distribution
    MathRandomGamma(alpha,beta,n,data);
    //--- calculate the data to plot the histogram
    CalculateHistogramArray(data,x,y,max,min,ncells);
    //--- obtain the sequence boundaries and the step for plotting the theoretical curve
    double step;
    GetMaxMinStepValues(max,min,step);
    step=MathMin(step,(max-min)/ncells);
    //--- obtain the theoretically calculated data at the interval of [min,max]
    double x2[];
    double y2[];
    MathSequence(min,max,step,x2);
    MathProbabilityDensityGamma(x2,alpha,beta,false,y2);
    //--- set the scale
    double theor_max=y2[ArrayMaximum(y2)];
    double sample_max=y[ArrayMaximum(y)];
    double k=sample_max/theor_max;
    for(int i=0; i<ncells; i++)
```

```

        y[i]/=k;
//--- output charts
    CGraphic graphic;
    if(ObjectFind(chart,name)<0)
        graphic.Create(chart,name,0,0,0,780,380);
    else
        graphic.Attach(chart,name);
    graphic.BackgroundMain(StringFormat("Gamma distribution alpha=%G beta=%G",alpha,beta));
    graphic.BackgroundMainSize(16);
//--- disable automatic scaling of the Y axis
    graphic.YAxis().AutoScale(false);
    graphic.YAxis().Max(NormalizeDouble(theor_max,1));
    graphic.YAxis().Min(0);
//--- plot all curves
    graphic.CurveAdd(x,y,CURVE_HISTOGRAM,"Sample").HistogramWidth(6);
//--- and now plot the theoretical curve of the distribution density
    graphic.CurveAdd(x2,y2,CURVE_LINES,"Theory");
    graphic.CurvePlotAll();
//--- plot all curves
    graphic.Update();
}
//+-----+
//| Calculate frequencies for data set |
//+-----+
bool CalculateHistogramArray(const double &data[],double &intervals[],double &frequency[],
                           double &maxv,double &minv,const int cells=10)
{
    if(cells<=1) return (false);
    int size=ArraySize(data);

    if ((maxv-minv)/stepv<10)
        stepv/=10.;
}
```

MathProbabilityDensityNoncentralBeta

Calculates the value of the probability density function of gamma distribution with the a and b parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathProbabilityDensityNoncentralBeta(
    const double x,           // value of random variable
    const double a,           // the first parameter of the distribution (shape)
    const double b,           // the second parameter of the distribution (scale)
    const bool log_mode,      // calculate the logarithm of the value, if log_mode=true
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability density function of gamma distribution with the a and b parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathProbabilityDensityNoncentralBeta(
    const double x,           // value of random variable
    const double a,           // the first parameter of the distribution (shape)
    const double b,           // the second parameter of the distribution (scale)
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability density function of gamma distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false. Analog of the [dgamma\(\)](#) in R.

```
bool MathProbabilityDensityNoncentralBeta(
    const double& x[],        // array with the values of random variable
    const double a,           // the first parameter of the distribution (shape)
    const double b,           // the second parameter of the distribution (scale)
    const bool log_mode,      // flag to calculate the logarithm of the value, if log_mode=true
    double& result[]          // array for values of the probability density function
);
```

Calculates the value of the probability density function of gamma distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false.

```
bool MathProbabilityDensityNoncentralBeta(
    const double& x[],        // array with the values of random variable
    const double a,           // the first parameter of the distribution (shape)
    const double b,           // the second parameter of the distribution (scale)
    double& result[]          // array for values of the probability density function
);
```

Parameters

x
[in] Value of random variable.

x[]

[in] Array with the values of random variable.

a

[in] The first parameter of the distribution (shape).

b

[in] The second parameter of the distribution (scale).

log_mode

[in] Flag to calculate the logarithm of the value. If `log_mode=true`, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

MathCumulativeDistributionGamma

Calculates the probability distribution function of gamma distribution with the a and b parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionGamma(
    const double x,           // value of random variable
    const double a,           // the first parameter of the distribution (shape)
    const double b,           // the second parameter of the distribution (scale)
    const bool tail,          // flag of calculation, if true, then the probability
    const bool log_mode,      // calculate the logarithm of the value, if log_mode=true
    int& error_code           // variable to store the error code
);
```

Calculates the probability distribution function of gamma distribution with the a and b parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionGamma(
    const double x,           // value of random variable
    const double a,           // the first parameter of the distribution (shape)
    const double b,           // the second parameter of the distribution (scale)
    int& error_code           // variable to store the error code
);
```

Calculates the probability distribution function of gamma distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false. Analog of the [pgamma\(\)](#) in R.

```
bool MathCumulativeDistributionGamma(
    const double& x[],        // array with the values of random variable
    const double a,           // the first parameter of the distribution (shape)
    const double b,           // the second parameter of the distribution (scale)
    const bool tail,          // flag of calculation, if true, then the probability
    const bool log_mode,      // flag to calculate the logarithm of the value, if log_mode=true
    double& result[]         // array for values of the probability function
);
```

Calculates the probability distribution function of gamma distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false.

```
bool MathCumulativeDistributionGamma(
    const double& x[],        // array with the values of random variable
    const double a,           // the first parameter of the distribution (shape)
    const double b,           // the second parameter of the distribution (scale)
    double& result[]         // array for values of the probability function
);
```

Parameters

x
[in] Value of random variable.

x[]

[in] Array with the values of random variable.

a

[in] The first parameter of the distribution (shape).

b

[in] The second parameter of the distribution (scale)

tail

[in] Flag of calculation. If true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

MathQuantileGamma

For the specified *probability*, the function calculates the value of inverse gamma distribution function with the a and b parameters. In case of error it returns [NaN](#).

```
double MathQuantileGamma(
    const double probability, // probability value of random variable occurrence
    const double a,          // the first parameter of the distribution (shape)
    const double b,          // the second parameter of the distribution (scale)
    const bool tail,         // flag of calculation, if false, then calculation is
    const bool log_mode,     // flag of calculation, if log_mode=true, calculation
    int& error_code          // variable to store the error code
);
```

For the specified *probability*, the function calculates the value of inverse gamma distribution function with the a and b parameters. In case of error it returns [NaN](#).

```
double MathQuantileGamma(
    const double probability, // probability value of random variable occurrence
    const double a,          // the first parameter of the distribution (shape)
    const double b,          // the second parameter of the distribution (scale)
    int& error_code          // variable to store the error code
);
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse gamma distribution function with the a and b parameters. In case of error it returns false. Analog of the [qgamma\(\)](#) in R.

```
double MathQuantileGamma(
    const double& probability[], // array with probability values of random variable
    const double a,             // the first parameter of the distribution (shape)
    const double b,             // the second parameter of the distribution (scale)
    const bool tail,            // flag of calculation, if false, then calculation is
    const bool log_mode,        // flag of calculation, if log_mode=true, calculation
    double& result[]            // array with values of quantiles
);
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse gamma distribution function with the a and b parameters. In case of error it returns false.

```
bool MathQuantileGamma(
    const double& probability[], // array with probability values of random variable
    const double a,             // the first parameter of the distribution (shape)
    const double b,             // the second parameter of the distribution (scale)
    double& result[]            // array with values of quantiles
);
```

Parameters

probability

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

a

[in] The first parameter of the distribution (shape).

b

[in] The second parameter of the distribution (scale).

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

MathRandomGamma

Generates a pseudorandom variable distributed according to the law of gamma distribution with the *a* and *b* parameters. In case of error it returns [NaN](#).

```
double MathRandomGamma (
    const double a,           // the first parameter of the distribution (shape)
    const double b,           // the second parameter of the distribution (scale)
    int& error_code           // variable to store the error code
);
```

Generates pseudorandom variables distributed according to the law of gamma distribution with the *a* and *b* parameters. In case of error it returns false. Analog of the [rgamma\(\)](#) in R.

```
bool MathRandomGamma (
    const double a,           // the first parameter of the distribution (shape)
    const double b,           // the second parameter of the distribution (scale)
    const int data_count,     // amount of required data
    double& result[]          // array with values of pseudorandom variables
);
```

Parameters

a

[in] The first parameter of the distribution (shape).

b

[in] The second parameter of the distribution (scale).

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

MathMomentsGamma

Calculates the theoretical numerical values of the first 4 moments of the gamma distribution with the a and b parameters.

```
double MathMomentsGamma(  
    const double a,           // the first parameter of the distribution (shape)  
    const double b,           // the second parameter of the distribution (scale)  
    double& mean,             // variable for the mean  
    double& variance,         // variable for the variance  
    double& skewness,         // variable for the skewness  
    double& kurtosis,         // variable for the kurtosis  
    int& error_code           // variable for the error code  
);
```

Parameters

a

[in] The first parameter of the distribution (shape).

b

[in] The second parameter of the distribution (scale).

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

Chi-squared distribution

This section contains functions for working with chi-squared distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the corresponding law. The chi-squared distribution is defined by the following formula:

$$f_{Chi-Square}(x|\nu) = \frac{x^{\frac{(\nu-2)}{2}} e^{-\frac{x}{2}}}{2^{\frac{\nu}{2}} \Gamma\left(\frac{\nu}{2}\right)}$$

where:

- x – value of the random variable
- ν – number of degrees of freedom

In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityChiSquare	Calculates the probability density function of the chi-squared distribution
MathCumulativeDistributionChiSquare	Calculates the value of the chi-squared probability distribution function
MathQuantileChiSquare	Calculates the value of the inverse chi-squared distribution function for the specified probability
MathRandomChiSquare	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the chi-squared distribution law

MathMomentsChiSquare

Calculates the theoretical numerical values of the first 4 moments of the chi-squared distribution

Example:

```
#include <Graphics\Graphic.mqh>
#include <Math\Stat\ChiSquare.mqh>
#include <Math\Stat\Math.mqh>
#property script_show_inputs
//--- input parameters
input double nu_par=5;    // the number of degrees of freedom
//+-----+
//| Script program start function |
//+-----+
void OnStart()
{
//--- hide the price chart
    ChartSetInteger(0,CHART_SHOW,false);
//--- initialize the random number generator
    MathSrand(GetTickCount());
//--- generate a sample of the random variable
    long chart=0;
    string name="GraphicNormal";
    int n=1000000;        // the number of values in the sample
    int ncells=51;        // the number of intervals in the histogram
    double x[];           // centers of the histogram intervals
    double y[];           // the number of values from the sample falling within the int
    double data[];        // sample of random values
    double max,min;       // the maximum and minimum values in the sample
//--- obtain a sample from the chi-squared distribution
    MathRandomChiSquare(nu_par,n,data);
//--- calculate the data to plot the histogram
    CalculateHistogramArray(data,x,y,max,min,ncells);
//--- obtain the sequence boundaries and the step for plotting the theoretical curve
    double step;
    GetMaxMinStepValues(max,min,step);
    step=MathMin(step,(max-min)/ncells);
//--- obtain the theoretically calculated data at the interval of [min,max]
    double x2[];
    double y2[];
    MathSequence(min,max,step,x2);
    MathProbabilityDensityChiSquare(x2,nu_par,false,y2);
//--- set the scale
    double theor_max=y2[ArrayMaximum(y2)];
    double sample_max=y[ArrayMaximum(y)];
    double k=sample_max/theor_max;
    for(int i=0; i<ncells; i++)
```

```

        y[i]/=k;
//--- output charts
    CGraphic graphic;
    if(ObjectFind(chart,name)<0)
        graphic.Create(chart,name,0,0,0,780,380);
    else
        graphic.Attach(chart,name);
    graphic.BackgroundMain(StringFormat("ChiSquare distribution nu=%G ",nu_par));
    graphic.BackgroundMainSize(16);
//--- plot all curves

//--- and now plot the theoretical curve of the distribution density
    graphic.CurveAdd(x2,y2,CURVE_LINES,"Theory");
    graphic.CurvePlotAll();
//--- plot all curves
    graphic.Update();
}
//+-----+
//| Calculate frequencies for data set |
//+-----+
bool CalculateHistogramArray(const double &data[],double &intervals[],double &frequency[],
                             double &maxv,double &minv,const int cells=10)
{
    if(cells<=1) return (false);
    int size=ArraySize(data);
    if(size<cells*10) return (false);
    minv=data[ArrayMinimum(data)];
    maxv=data[ArrayMaximum(data)];
    double range=maxv-minv;
    double width=range/cells;
    if(width==0) return false;
    ArrayResize(intervals,cells);
    ArrayResize(frequency,cells);
//--- define the interval centers
    for(int i=0; i<cells; i++)
    {
        intervals[i]=minv+(i+0.5)*width;
        frequency[i]=0;
    }
//--- fill the frequencies of falling within the interval
    for(int i=0; i<size; i++)
    {
        int ind=int((data[i]-minv)/width);
        if(ind>=cells) ind=cells-1;
        frequency[ind]++;
    }
    return (true);
}
//+-----+

```

```
///| Calculates values for sequence generation |
///+-----+
void GetMaxMinStepValues(double &maxv, double &minv, double &stepv)
{
    ///--- calculate the absolute range of the sequence to obtain the precision of normalization
    double range=MathAbs(maxv-minv);
    int degree=(int)MathRound(MathLog10(range));
    ///--- normalize the maximum and minimum values to the specified precision
    maxv=NormalizeDouble(maxv, degree);
    minv=NormalizeDouble(minv, degree);
    ///--- sequence generation step is also set based on the specified precision
    stepv=NormalizeDouble(MathPow(10, -degree), degree);
    if((maxv-minv)/stepv<10)
        stepv/=10.;
}
```

MathProbabilityDensityChiSquare

Calculates the value of the probability density function of chi-squared distribution with the *nu* parameter for a random variable *x*. In case of error it returns [NaN](#).

```
double MathProbabilityDensityChiSquare(
    const double x,           // value of random variable
    const double nu,          // parameter of distribution (number of degrees of freedom)
    const bool log_mode,      // calculate the logarithm of the value, if log_mode=true
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability density function of chi-squared distribution with the *nu* parameter for a random variable *x*. In case of error it returns [NaN](#).

```
double MathProbabilityDensityChiSquare(
    const double x,           // value of random variable
    const double nu,          // parameter of distribution (number of degrees of freedom)
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability density function of chi-squared distribution with the *nu* parameter for an array of random variables *x[]*. In case of error it returns false. Analog of the [dchisq\(\)](#) in R.

```
bool MathProbabilityDensityChiSquare(
    const double& x[],        // array with the values of random variable
    const double nu,          // parameter of distribution (number of degrees of freedom)
    const bool log_mode,      // flag to calculate the logarithm of the value, if log_mode=true
    double& result[]          // array for values of the probability density function
);
```

Calculates the value of the probability density function of chi-squared distribution with the *nu* parameter for an array of random variables *x[]*. In case of error it returns false.

```
bool MathProbabilityDensityChiSquare(
    const double& x[],        // array with the values of random variable
    const double nu,          // parameter of distribution (number of degrees of freedom)
    double& result[]          // array for values of the probability density function
);
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

nu

[in] Parameter of distribution (number of degrees of freedom)

log_mode

[in] Flag to calculate the logarithm of the value. If `log_mode=true`, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

MathCumulativeDistributionChiSquare

Calculates the probability distribution function of chi-squared distribution with the nu parameter for a random variable x. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionChiSquare (
    const double x,           // value of random variable
    const double nu,          // parameter of distribution (number of degrees of freedom)
    const bool tail,          // flag of calculation, if true, then the probability of exceeding
    const bool log_mode,      // calculate the logarithm of the value, if log_mode=true
    int& error_code           // variable to store the error code
);
```

Calculates the probability distribution function of chi-squared distribution with the nu parameter for a random variable x. In case of error it returns [NaN](#)

```
double MathCumulativeDistributionChiSquare (
    const double x,           // value of random variable
    const double nu,          // parameter of distribution (number of degrees of freedom)
    int& error_code           // variable to store the error code
);
```

Calculates the probability distribution function of chi-squared distribution with the nu parameter for an array of random variables x[]. In case of error it returns false. Analog of the [pchisq\(\)](#) in R.

```
bool MathCumulativeDistributionChiSquare (
    const double& x[],        // array with the values of random variable
    const double nu,          // parameter of distribution (number of degrees of freedom)
    const bool tail,          // flag of calculation, if true, then the probability of exceeding
    const bool log_mode,      // flag to calculate the logarithm of the value, if log_mode=true
    double& result[]         // array for values of the probability function
);
```

Calculates the probability distribution function of chi-squared distribution with the nu parameter for an array of random variables x[]. In case of error it returns false.

```
bool MathCumulativeDistributionChiSquare (
    const double& x[],        // array with the values of random variable
    const double nu,          // parameter of distribution (number of degrees of freedom)
    double& result[]         // array for values of the probability function
);
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

nu

[in] Parameter of distribution (number of degrees of freedom).

tail

[in] Flag of calculation. If true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

MathQuantileChiSquare

For the specified *probability*, the function calculates the value of inverse chi-squared distribution function. In case of error it returns [NaN](#).

```
double MathQuantileChiSquare(
    const double probability, // probability value of random variable occurrence
    const double nu,         // parameter of distribution (number of degrees of fr
    const bool tail,         // flag of calculation, if false, then calculation is
    const bool log_mode,     // flag of calculation, if log_mode=true, calculation
    int& error_code          // variable to store the error code
);
```

For the specified *probability*, the function calculates the value of inverse chi-squared distribution function. In case of error it returns [NaN](#).

```
double MathQuantileChiSquare(
    const double probability, // probability value of random variable occurrence
    const double nu,         // parameter of distribution (number of degrees of fr
    int& error_code          // variable to store the error code
);
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse chi-squared distribution function. In case of error it returns false. Analog of the [gchisq\(\)](#) in R.

```
double MathQuantileChiSquare(
    const double& probability[], // array with probability values of random variable
    const double nu,            // parameter of distribution (number of degrees of fr
    const bool tail,            // flag of calculation, if false, then calculation is
    const bool log_mode,        // flag of calculation, if log_mode=true, calculation
    double& result[]            // array with values of quantiles
);
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse chi-squared distribution function. In case of error it returns false.

```
bool MathQuantileChiSquare(
    const double& probability[], // array with probability values of random variable
    const double nu,            // parameter of distribution (number of degrees of fr
    double& result[]            // array with values of quantiles
);
```

Parameters

probability

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

nu

[in] Parameter of distribution (number of degrees of freedom).

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

MathRandomChiSquare

Generates a pseudorandom variable distributed according to the law of chi-squared distribution with the *nu* parameter. In case of error it returns [NaN](#).

```
double MathRandomChiSquare (
    const double  nu,           // parameter of distribution (number of degrees of freedom)
    int&          error_code     // variable to store the error code
);
```

Generates pseudorandom variables distributed according to the law of chi-squared distribution with the *nu* parameter. In case of error it returns false. Analog of the [rchisq\(\)](#) in R.

```
bool MathRandomChiSquare (
    const double  nu,           // parameter of distribution (number of degrees of freedom)
    const int     data_count,    // amount of required data
    double&       result[]      // array with values of pseudorandom variables
);
```

Parameters

nu

[in] Parameter of distribution (number of degrees of freedom).

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

MathMomentsChiSquare

Calculates the theoretical numerical values of the first 4 moments of the chi-squared distribution with the nu parameter.

```
double MathMomentsChiSquare(  
    const double  nu,           // parameter of distribution (number of degrees of fr  
    double&       mean,         // variable for the mean  
    double&       variance,     // variable for the variance  
    double&       skewness,     // variable for the skewness  
    double&       kurtosis,     // variable for the kurtosis  
    int&         error_code     // variable for the error code  
);
```

Parameters

nu

[in] Parameter of distribution (number of degrees of freedom).

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

Noncentral chi-squared distribution

This section contains functions for working with noncentral chi-squared distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the corresponding law. The noncentral chi-squared distribution is defined by the following formula:

$$f_{NoncentralChiSquare}(x|v,\sigma) = \frac{1}{2^{\frac{v}{2}}\Gamma(\frac{1}{2})} x^{\frac{v}{2}-1} e^{-\frac{(x+\sigma)}{2}} \sum_{r=0}^{\infty} \frac{(\lambda x)^r}{(2r)!} \frac{\Gamma(\frac{1}{2}+r)}{\Gamma(\frac{v}{2}+r)}$$

where:

- x – value of the random variable
- v – number of degrees of freedom
- σ – noncentrality parameter

In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityNoncentralChiSquare	Calculates the probability density function of the noncentral chi-squared distribution
MathCumulativeDistributionNoncentralChiSquare	Calculates the value of the noncentral chi-squared probability distribution function
MathQuantileNoncentralChiSquare	Calculates the value of the inverse noncentral chi-squared distribution function for the specified probability
MathRandomNoncentralChiSquare	Generates a pseudorandom variable/array of pseudorandom variables distributed according

	to the noncentral chi-squared distribution law
<u>MathMomentsNoncentralChiSquare</u>	Calculates the theoretical numerical values of the first 4 moments of the noncentral chi-squared distribution

Example:

```

#include <Graphics\Graphic.mqh>
#include <Math\Stat\NoncentralChiSquare.mqh>
#include <Math\Stat\Math.mqh>

```

MathProbabilityDensityNoncentralChiSquare

Calculates the value of the probability density function of noncentral chi-squared distribution with the nu and sigma parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathProbabilityDensityNoncentralChiSquare(
    const double x,           // value of random variable
    const double nu,          // parameter of distribution (number of degrees of freedom)
    const double sigma,       // noncentrality parameter
    const bool log_mode,      // calculate the logarithm of the value, if log_mode=true
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability density function of noncentral chi-squared distribution with the nu and sigma parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathProbabilityDensityNoncentralChiSquare(
    const double x,           // value of random variable
    const double nu,          // parameter of distribution (number of degrees of freedom)
    const double sigma,       // noncentrality parameter
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability density function of noncentral chi-squared distribution with the nu and sigma parameters for an array of random variables x[]. In case of error it returns false. Analog of the [dchisq\(\)](#) in R.

```
bool MathProbabilityDensityNoncentralChiSquare(
    const double& x[],        // array with the values of random variable
    const double nu,          // parameter of distribution (number of degrees of freedom)
    const double sigma,       // noncentrality parameter
    const bool log_mode,      // flag to calculate the logarithm of the value, if log_mode=true
    double& result[]         // array for values of the probability density function
);
```

Calculates the value of the probability density function of noncentral chi-squared distribution with the nu parameter for an array of random variables x[]. In case of error it returns false.

```
bool MathProbabilityDensityNoncentralChiSquare(
    const double& x[],        // array with the values of random variable
    const double nu,          // parameter of distribution (number of degrees of freedom)
    const double sigma,       // noncentrality parameter
    double& result[]         // array for values of the probability density function
);
```

Parameters

x
[in] Value of random variable.

x[]

[in] Array with the values of random variable.

nu

[in] Parameter of distribution (number of degrees of freedom).

sigma

[in] Noncentrality parameter.

log_mode

[in] Flag to calculate the logarithm of the value. If `log_mode=true`, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

MathCumulativeDistributionNoncentralChiSquare

Calculates the probability distribution function of noncentral chi-squared distribution with the nu and sigma parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionNoncentralChiSquare(
    const double x,           // value of random variable
    const double nu,          // parameter of distribution (number of degrees of freedom)
    const double sigma,       // noncentrality parameter
    const bool tail,          // flag of calculation, if lower_tail=true, then the probability is calculated for the lower tail
    const bool log_mode,      // calculate the logarithm of the value, if log_mode=true
    int& error_code           // variable to store the error code
);
```

Calculates the probability distribution function of noncentral chi-squared distribution with the nu and sigma parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionNoncentralChiSquare(
    const double x,           // value of random variable
    const double nu,          // parameter of distribution (number of degrees of freedom)
    const double sigma,       // noncentrality parameter
    int& error_code           // variable to store the error code
);
```

Calculates the probability distribution function of noncentral chi-squared distribution with the nu and sigma parameters for an array of random variables x[]. In case of error it returns false. Analog of the [pchisq\(\)](#) in R.

```
bool MathCumulativeDistributionNoncentralChiSquare(
    const double& x[],        // array with the values of random variable
    const double nu,          // parameter of distribution (number of degrees of freedom)
    const double sigma,       // noncentrality parameter
    const bool tail,          // flag of calculation, if lower_tail=true, then the probability is calculated for the lower tail
    const bool log_mode,      // flag to calculate the logarithm of the value, if log_mode=true
    double& result[]          // array for values of the probability function
);
```

Calculates the probability distribution function of noncentral chi-squared distribution with the nu and sigma parameters for an array of random variables x[]. In case of error it returns false.

```
bool MathCumulativeDistributionNoncentralChiSquare(
    const double& x[],        // array with the values of random variable
    const double nu,          // parameter of distribution (number of degrees of freedom)
    const double sigma,       // noncentrality parameter
    double& result[]          // array for values of the probability function
);
```

Parameters

x
[in] Value of random variable.

x[]

[in] Array with the values of random variable.

nu

[in] Parameter of distribution (number of degrees of freedom).

sigma

[in] Noncentrality parameter.

tail

[in] Flag of calculation. If true, then the probability of random variable not exceeding *x* is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If *log_mode*=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

MathQuantileNoncentralChiSquare

For the specified *probability*, the function calculates the value of inverse noncentral chi-squared distribution function with the *nu* and *sigma* parameters. In case of error it returns [NaN](#).

```
double MathQuantileNoncentralChiSquare(
    const double probability, // probability value of random variable occurrence
    const double nu,         // parameter of distribution (number of degrees of fr
    const double sigma,      // noncentrality parameter
    const bool tail,         // flag of calculation, if false, then calculation is
    const bool log_mode,     // flag of calculation, if log_mode=true, calculation
    int& error_code          // variable to store the error code
);
```

For the specified *probability*, the function calculates the value of inverse noncentral chi-squared distribution function with the *nu* and *sigma* parameters. In case of error it returns [NaN](#).

```
double MathQuantileNoncentralChiSquare(
    const double probability, // probability value of random variable occurrence
    const double nu,         // parameter of distribution (number of degrees of fr
    const double sigma,      // noncentrality parameter
    int& error_code          // variable to store the error code
);
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse noncentral chi-squared distribution function with the *nu* and *sigma* parameters. In case of error it returns false. Analog of the [qchisq\(\)](#) in R.

```
double MathQuantileNoncentralChiSquare(
    const double& probability[], // array with probability values of random variable
    const double nu,            // parameter of distribution (number of degrees of fr
    const double sigma,         // noncentrality parameter
    const bool tail,            // flag of calculation, if false, then calculation is
    const bool log_mode,        // flag of calculation, if log_mode=true, calculation
    double& result[]            // array with values of quantiles
);
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse noncentral chi-squared distribution function. In case of error it returns false.

```
bool MathQuantileNoncentralChiSquare(
    const double& probability[], // array with probability values of random variable
    const double nu,            // parameter of distribution (number of degrees of fr
    const double sigma,         // noncentrality parameter
    double& result[]            // array with values of quantiles
);
```

Parameters

probability

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

nu

[in] Parameter of distribution (number of degrees of freedom).

sigma

[in] Noncentrality parameter.

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

MathRandomNoncentralChiSquare

Generates a pseudorandom variable distributed according to the law of noncentral chi-squared distribution with the *nu* and *sigma* parameters. In case of error it returns [NaN](#).

```
double MathRandomNoncentralChiSquare(  
    const double nu,           // parameter of distribution (number of degrees of freedom)  
    const double sigma,        // noncentrality parameter  
    int& error_code            // variable to store the error code  
);
```

Generates pseudorandom variables distributed according to the law of noncentral chi-squared distribution with the *nu* and *sigma* parameters. In case of error it returns false. Analog of the [rchisq\(\)](#) in R.

```
bool MathRandomNoncentralChiSquare(  
    const double nu,           // parameter of distribution (number of degrees of freedom)  
    const double sigma,        // noncentrality parameter  
    const int data_count,      // amount of required data  
    double& result[]           // array with values of pseudorandom variables  
);
```

Parameters

nu

[in] Parameter of distribution (number of degrees of freedom).

sigma

[in] Noncentrality parameter.

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

MathMomentsNoncentralChiSquare

Calculates the theoretical numerical values of the first 4 moments of the noncentral chi-squared distribution with the nu and sigma parameters.

```
double MathMomentsNoncentralChiSquare(  
    const double nu,           // parameter of distribution (number of degrees of freedom)  
    const double sigma,        // noncentrality parameter  
    double& mean,              // variable for the mean  
    double& variance,          // variable for the variance  
    double& skewness,          // variable for the skewness  
    double& kurtosis,          // variable for the kurtosis  
    int& error_code             // variable for the error code  
);
```

Parameters

nu

[in] Parameter of distribution (number of degrees of freedom).

sigma

[in] Noncentrality parameter.

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

Exponential

This section contains functions for working with exponential distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the law of exponential distribution. The exponential distribution is defined by the following formula:

$$f_{\text{Exponential}}(x|\mu) = \frac{1}{\mu} e^{-\frac{x}{\mu}}$$

where:

- x — value of the random variable
- μ — expected value

In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
<u>MathProbabilityDensityExponential</u>	Calculates the probability density function of the exponential distribution
<u>MathCumulativeDistributionExponential</u>	Calculates the value of the exponential probability distribution function
<u>MathQuantileExponential</u>	Calculates the value of the inverse exponential distribution function for the specified probability
<u>MathRandomExponential</u>	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the law of exponential distribution
<u>MathMomentsExponential</u>	Calculates the theoretical numerical values of the first 4 moments of the exponential

distribution

Example:

```

#include <Graphics\Graphic.mqh>
#include <Math\Stat\Exponential.mqh>
#include <Math\Stat\Math.mqh>
#property script_show_inputs
//--- input parameters
input double mu_par=1.5;    // the number of degrees of freedom
//+-----+
//| Script program start function |
//+-----+
void OnStart()
{
//--- hide the price chart
    ChartSetInteger(0,CHART_SHOW,false);
//--- initialize the random number generator
    MathSrand(GetTickCount());
//--- generate a sample of the random variable
    long chart=0;
    string name="GraphicNormal";
    int n=1000000;        // the number of values in the sample
    int ncells=51;        // the number of intervals in the histogram
    double x[];           // centers of the histogram intervals
    double y[];           // the number of values from the sample falling within the int
    double data[];        // sample of random values
    double max,min;       // the maximum and minimum values in the sample
//--- obtain a sample from the exponential distribution
    MathRandomExponential(mu_par,n,data);
//--- calculate the data to plot the histogram
    CalculateHistogramArray(data,x,y,max,min,ncells);
//--- obtain the sequence boundaries and the step for plotting the theoretical curve
    double step;
    GetMaxMinStepValues(max,min,step);
    step=MathMin(step,(max-min)/ncells);
//--- obtain the theoretically calculated data at the interval of [min,max]
    double x2[];
    double y2[];
    MathSequence(min,max,step,x2);
    MathProbabilityDensityExponential(x2,mu_par,false,y2);
//--- set the scale
    double theor_max=y2[ArrayMaximum(y2)];
    double sample_max=y[ArrayMaximum(y)];
    double k=sample_max/theor_max;
    for(int i=0; i<ncells; i++)
        y[i]/=k;
//--- output charts

    if((maxv-minv)/stepv<10)
        stepv/=10.;
}
```

MathProbabilityDensityExponential

Calculates the value of the probability density function of exponential distribution with the μ parameter for a random variable x . In case of error it returns [NaN](#).

```
double MathProbabilityDensityExponential(
    const double x,           // value of random variable
    const double mu,          // parameter of the distribution (expected value)
    const bool log_mode,      // calculate the logarithm of the value, if log_mode=true
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability density function of exponential distribution with the μ parameter for a random variable x . In case of error it returns [NaN](#).

```
double MathProbabilityDensityExponential(
    const double x,           // value of random variable
    const double mu,          // parameter of the distribution (expected value)
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability density function of exponential distribution with the μ parameter for an array of random variables $x[]$. In case of error it returns false. Analog of the [dexp\(\)](#) in R.

```
bool MathProbabilityDensityExponential(
    const double& x[],         // array with the values of random variable
    const double mu,           // parameter of the distribution (expected value)
    const bool log_mode,       // flag to calculate the logarithm of the value, if log_mode=true
    double& result[]           // array for values of the probability density function
);
```

Calculates the value of the probability density function of exponential distribution with the μ parameter for an array of random variables $x[]$. In case of error it returns false.

```
bool MathProbabilityDensityExponential(
    const double& x[],         // array with the values of random variable
    const double mu,           // parameter of the distribution (expected value)
    double& result[]           // array for values of the probability density function
);
```

Parameters

x

[in] Value of random variable.

$x[]$

[in] Array with the values of random variable.

μ

[in] Parameter of the distribution (expected value)

\log_mode

[in] Flag to calculate the logarithm of the value. If `log_mode=true`, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

MathCumulativeDistributionExponential

Calculates the exponential distribution function of probabilities with the mu parameter for a random variable x. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionExponential(
    const double x,           // value of random variable
    const double mu,          // parameter of the distribution (expected value)
    const bool tail,          // flag of calculation, if true, then the probability
    const bool log_mode,      // calculate the logarithm of the value, if log_mode=true
    int& error_code           // variable to store the error code
);
```

Calculates the exponential distribution function of probabilities with the mu parameter for a random variable x. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionExponential(
    const double x,           // value of random variable
    const double mu,          // parameter of the distribution (expected value)
    int& error_code           // variable to store the error code
);
```

Calculates the exponential distribution function of probabilities with the mu parameter for an array of random variables x[]. In case of error it returns false. Analog of the [pexp\(\)](#) in R.

```
bool MathCumulativeDistributionExponential(
    const double& x[],        // array with the values of random variable
    const double mu,          // parameter of the distribution (expected value)
    const bool tail,          // flag of calculation, if true, then the probability
    const bool log_mode,      // flag to calculate the logarithm of the value, if log_mode=true
    double& result[]         // array for values of the probability function
);
```

Calculates the exponential distribution function of probabilities with the mu parameter for an array of random variables x[]. In case of error it returns false.

```
bool MathCumulativeDistributionExponential(
    const double& x[],        // array with the values of random variable
    const double mu,          // parameter of the distribution (expected value)
    double& result[]         // array for values of the probability function
);
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

mu

[in] Parameter of the distribution (expected value).

tail

[in] Flag of calculation. If true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

MathQuantileExponential

For the specified *probability*, the function calculates the value of inverse exponential distribution function with the *mu* parameter. In case of error it returns [NaN](#).

```
double MathQuantileExponential(
    const double probability, // probability value of random variable occurrence
    const double mu,         // parameter of the distribution (expected value)
    const bool tail,         // flag of calculation, if false, then calculation is
    const bool log_mode,     // flag of calculation, if log_mode=true, calculation
    int& error_code          // variable to store the error code
);
```

For the specified *probability*, the function calculates the value of inverse exponential distribution function with the *mu* parameter. In case of error it returns [NaN](#).

```
double MathQuantileExponential(
    const double probability, // probability value of random variable occurrence
    const double mu,         // parameter of the distribution (expected value)
    int& error_code          // variable to store the error code
);
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse exponential distribution function with the *mu* parameter. In case of error it returns false. Analog of the [qexp\(\)](#) in R.

```
double MathQuantileExponential(
    const double& probability[], // array with probability values of random variable
    const double mu,            // parameter of the distribution (expected value)
    const bool tail,            // flag of calculation, if false, then calculation is
    const bool log_mode,        // flag of calculation, if log_mode=true, calculation
    double& result[]            // array with values of quantiles
);
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse exponential distribution function with the *mu* parameter. In case of error it returns false.

```
bool MathQuantileExponential(
    const double& probability[], // array with probability values of random variable
    const double mu,            // parameter of the distribution (expected value)
    double& result[]            // array with values of quantiles
);
```

Parameters

probability

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

mu

[in] Parameter of the distribution (expected value).

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

MathRandomExponential

Generates a pseudorandom variable distributed according to the law of exponential distribution with the μ parameter. In case of error it returns [NaN](#).

```
double MathRandomExponential(  
    const double mu,           // parameter of the distribution (expected value)  
    int& error_code           // variable to store the error code  
);
```

Generates pseudorandom variables distributed according to the law of exponential distribution with the μ parameter. In case of error it returns false. Analog of the [rexp\(\)](#) in R.

```
bool MathRandomExponential(  
    const double mu,           // parameter of the distribution (expected value)  
    const int data_count,      // amount of required data  
    double& result[]          // array with values of pseudorandom variables  
);
```

Parameters

mu

[in] Parameter of the distribution (expected value).

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

MathMomentsExponential

Calculates the theoretical numerical values of the first 4 moments of the exponential distribution with the mu parameter.

```
double MathMomentsExponential(  
    const double mu,           // parameter of the distribution (expected value)  
    double& mean,              // variable for the mean  
    double& variance,          // variable for the variance  
    double& skewness,          // variable for the skewness  
    double& kurtosis,          // variable for the kurtosis  
    int& error_code            // variable for the error code  
);
```

Parameters

mu

[in] Parameter of the distribution (expected value).

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

F-distribution

This section contains functions for working with F-distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the law of Fisher's F-distribution. The F-distribution is defined by the following formula:

$$f_F(x|v_1,v_2)=\frac{\Gamma\left(\frac{v_1+v_2}{2}\right)}{\Gamma\left(\frac{v_1}{2}\right)\Gamma\left(\frac{v_2}{2}\right)}\left(\frac{v_1}{v_2}\right)^{\frac{v_1}{2}}\frac{x^{\frac{v_1-2}{2}}}{\left(1+\left(\frac{v_1}{v_2}\right)x\right)^{\frac{v_1+v_2}{2}}}$$

where:

- x — value of the random variable
- v1 — the first parameter of distribution (number of degrees of freedom)
- v2 — the second parameter of distribution (number of degrees of freedom)

In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityF	Calculates the probability density function of the F-distribution
MathCumulativeDistributionF	Calculates the value of the F-distribution function
MathQuantileF	Calculates the value of the inverse F-distribution function for the specified probability

<u>MathRandomF</u>	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the Fisher's law
<u>MathMomentsF</u>	Calculates the theoretical numerical values of the first 4 moments of the Fisher's F-distribution

Example:

```

#include <Graphics\Graphic.mqh>
#include <Math\Stat\F.mqh>
#include <Math\Stat\Math.mqh>
#property script_show_inputs
//--- input parameters
input double nu_1=100;    // the first number of degrees of freedom

    if ((maxv-minv)/stepv<10)
        stepv/=10.;
}
```

MathProbabilityDensityF

Calculates the value of the probability density function of Fisher's F-distribution with the nu1 and nu2 parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathProbabilityDensityF(
    const double x,           // value of random variable
    const double nu1,         // the first parameter of distribution (number of degrees of freedom)
    const double nu2,         // the second parameter of distribution (number of degrees of freedom)
    const bool log_mode,      // calculate the logarithm of the value, if log_mode=true
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability density function of Fisher's F-distribution with the nu1 and nu2 parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathProbabilityDensityF(
    const double x,           // value of random variable
    const double nu1,         // the first parameter of distribution (number of degrees of freedom)
    const double nu2,         // the second parameter of distribution (number of degrees of freedom)
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability density function of Fisher's F-distribution with the nu1 and nu2 parameters for an array of random variables x[]. In case of error it returns false. Analog of the [df\(\)](#) in R.

```
bool MathProbabilityDensityF(
    const double& x[],        // array with the values of random variable
    const double nu1,         // the first parameter of distribution (number of degrees of freedom)
    const double nu2,         // the second parameter of distribution (number of degrees of freedom)
    const bool log_mode,      // flag to calculate the logarithm of the value, if log_mode=true
    double& result[]          // array for values of the probability density function
);
```

Calculates the value of the probability density function of Fisher's F-distribution with the nu1 and nu2 parameters for an array of random variables x[]. In case of error it returns false.

```
bool MathProbabilityDensityF(
    const double& x[],        // array with the values of random variable
    const double nu1,         // the first parameter of distribution (number of degrees of freedom)
    const double nu2,         // the second parameter of distribution (number of degrees of freedom)
    double& result[]          // array for values of the probability density function
);
```

Parameters

x
[in] Value of random variable.

x[]

[in] Array with the values of random variable.

nu1

[in] The first parameter of distribution (number of degrees of freedom).

nu2

[in] The second parameter of distribution (number of degrees of freedom).

log_mode

[in] Flag to calculate the logarithm of the value. If `log_mode=true`, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

MathCumulativeDistributionF

Calculates the value of the probability distribution function of Fisher's F-distribution with the nu1 and nu2 parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionF(
    const double x,           // value of random variable
    const double nu1,         // the first parameter of distribution (number of degrees of freedom)
    const double nu2,         // the second parameter of distribution (number of degrees of freedom)
    const bool tail,          // flag of calculation, if true, then the probability of exceeding the value is calculated
    const bool log_mode,      // calculate the logarithm of the value, if log_mode=true
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability distribution function of Fisher's F-distribution with the nu1 and nu2 parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionF(
    const double x,           // value of random variable
    const double nu1,         // the first parameter of distribution (number of degrees of freedom)
    const double nu2,         // the second parameter of distribution (number of degrees of freedom)
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability distribution function of Fisher's F-distribution with the nu1 and nu2 parameters for an array of random variables x[]. In case of error it returns false. Analog of the [pf\(\)](#) in R.

```
bool MathCumulativeDistributionF(
    const double& x[],        // array with the values of random variable
    const double nu1,         // the first parameter of distribution (number of degrees of freedom)
    const double nu2,         // the second parameter of distribution (number of degrees of freedom)
    const bool tail,          // flag of calculation, if true, then the probability of exceeding the value is calculated
    const bool log_mode,      // calculate the logarithm of the value, if log_mode=true
    double& result[]         // array for values of the probability function
);
```

Calculates the value of the probability distribution function of Fisher's F-distribution with the nu1 and nu2 parameters for an array of random variables x[]. In case of error it returns false.

```
bool MathCumulativeDistributionF(
    const double& x[],        // array with the values of random variable
    const double nu1,         // the first parameter of distribution (number of degrees of freedom)
    const double nu2,         // the second parameter of distribution (number of degrees of freedom)
    double& result[]         // array for values of the probability function
);
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

nu1

[in] The first parameter of distribution (number of degrees of freedom).

nu2

[in] The second parameter of distribution (number of degrees of freedom).

tail

[in] Flag of calculation. If true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

MathQuantileF

For the specified *probability*, the function calculates the value of inverse Fisher's F-distribution function with the *nu1* and *nu2* parameters. In case of error it returns [NaN](#).

```
double MathQuantileF(
    const double probability, // probability value of random variable occurrence
    const double nu1,        // the first parameter of distribution (number of degrees of freedom)
    const double nu2,        // the second parameter of distribution (number of degrees of freedom)
    const bool tail,         // flag of calculation, if false, then calculation is for the left tail
    const bool log_mode,     // flag of calculation, if log_mode=true, calculation is for the logarithm of the function
    int& error_code          // variable to store the error code
);
```

For the specified *probability*, the function calculates the value of inverse Fisher's F-distribution function with the *nu1* and *nu2* parameters. In case of error it returns [NaN](#).

```
double MathQuantileF(
    const double probability, // probability value of random variable occurrence
    const double nu1,        // the first parameter of distribution (number of degrees of freedom)
    const double nu2,        // the second parameter of distribution (number of degrees of freedom)
    int& error_code          // variable to store the error code
);
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse Fisher's F-distribution function with the *nu1* and *nu2* parameters. In case of error it returns false. Analog of the [qf\(\)](#) in R.

```
double MathQuantileF(
    const double& probability[], // array with probability values of random variable
    const double nu1,           // the first parameter of distribution (number of degrees of freedom)
    const double nu2,           // the second parameter of distribution (number of degrees of freedom)
    const bool tail,            // flag of calculation, if false, then calculation is for the left tail
    const bool log_mode,        // flag of calculation, if log_mode=true, calculation is for the logarithm of the function
    double& result[]            // array with values of quantiles
);
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse Fisher's F-distribution function with the *nu1* and *nu2* parameters. In case of error it returns false.

```
bool MathQuantileF(
    const double& probability[], // array with probability values of random variable
    const double nu1,           // the first parameter of distribution (number of degrees of freedom)
    const double nu2,           // the second parameter of distribution (number of degrees of freedom)
    double& result[]            // array with values of quantiles
);
```

Parameters

probability

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

nu1

[in] The first parameter of distribution (number of degrees of freedom).

nu2

[in] The second parameter of distribution (number of degrees of freedom).

tail

[in] Flag of calculation, if lower_tail=false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

MathRandomF

Generates a pseudorandom variable distributed according to the law of Fisher's F-distribution with the *nu1* and *nu2* parameters. In case of error it returns [NaN](#).

```
double MathRandomF(  
    const double nu1,           // the first parameter of distribution (number of de  
    const double nu2,           // the second parameter of distribution (number of de  
    int& error_code             // variable to store the error code  
);
```

Generates pseudorandom variables distributed according to the law of Fisher's F-distribution with the *nu1* and *nu2* parameters. In case of error it returns false. Analog of the [rf\(\)](#) in R.

```
bool MathRandomF(  
    const double nu1,           // the first parameter of distribution (number of de  
    const double nu2,           // the second parameter of distribution (number of de  
    const int data_count,       // amount of required data  
    double& result[]           // array with values of pseudorandom variables  
);
```

Parameters

nu1

[in] The first parameter of distribution (number of degrees of freedom).

nu2

[in] The second parameter of distribution (number of degrees of freedom).

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

MathMomentsF

Calculates the theoretical numerical values of the first 4 moments of the Fisher's F-distribution with the *nu1* and *nu2* parameters.

```
double MathMomentsF(  
    const double  nu1,           // the first parameter of distribution (number of de  
    const double  nu2,           // the second parameter of distribution (number of de  
    double&       mean,          // variable for the mean  
    double&       variance,      // variable for the variance  
    double&       skewness,     // variable for the skewness  
    double&       kurtosis,     // variable for the kurtosis  
    int&          error_code    // variable for the error code  
);
```

Parameters

nu1

[in] The first parameter of distribution (number of degrees of freedom).

nu2

[in] The second parameter of distribution (number of degrees of freedom).

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

Noncentral F-distribution

This section contains functions for working with noncentral F-distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the law of noncentral Fisher's F-distribution. The noncentral F-distribution is defined by the following formula:

$$f_{NoncentralF}(x|v_1,v_2,\sigma) = e^{-\frac{\sigma}{2}} \sum_{r=0}^{\infty} \frac{1}{r!} \left(\frac{\sigma}{2}\right)^r \frac{\Gamma\left(\frac{v_1+v_2}{2}+r\right)}{\Gamma\left(\frac{v_2}{2}+r\right)\Gamma\left(\frac{v_2}{2}\right)} \left(\frac{v_1}{v_2}\right)^{\frac{v_2}{2}+r} \frac{x^{\frac{v_2}{2}-1+r}}{\left(1+\frac{v_1}{v_2}x\right)^{\frac{v_1+v_2}{2}+r}}$$

where:

- x – value of the random variable
- v1 – the first parameter of distribution (number of degrees of freedom)
- v2 – the second parameter of distribution (number of degrees of freedom)
- σ – noncentrality parameter

In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityNoncentralF	Calculates the probability density function of the noncentral F-distribution
MathCumulativeDistributionNoncentralF	Calculates the value of the noncentral F-distribution function
MathQuantileNoncentralF	Calculates the value of the inverse noncentral F-distribution function for the specified probability

<u>MathRandomNoncentralF</u>	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the noncentral Fisher's distribution law
<u>MathMomentsNoncentralF</u>	Calculates the theoretical numerical values of the first 4 moments of the noncentral Fisher's F-distribution

Example:

```
#include <Graphics\Graphic.mqh>
#include <Math\Stat\NoncentralF.mqh>
#include <Math\Stat\Math.mqh>
#property script_show_inputs
//--- input parameters
input double nu_1=20;    // the first number of degrees of freedom
input double nu_2=20;    // the second number of degrees of freedom
input double sig=10;     // noncentrality parameter
//+-----+
//| Script program start function |
//+-----+
void OnStart()
{
//--- hide the price chart
    ChartSetInteger(0,CHART_SHOW,false);
//--- initialize the random number generator
    MathSrand(GetTickCount());
//--- generate a sample of the random variable
    long chart=0;

}
```

MathProbabilityDensityNoncentralF

Calculates the value of the probability density function of noncentral Fisher's F-distribution with the nu1, nu2 and sigma parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathProbabilityDensityNoncentralF(
    const double x,           // value of random variable
    const double nu1,         // the first parameter of distribution (number of degrees of freedom)
    const double nu2,         // the second parameter of distribution (number of degrees of freedom)
    const double sigma,       // noncentrality parameter
    const bool log_mode,      // calculate the logarithm of the value, if log_mode=true
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability density function of noncentral Fisher's F-distribution with the nu1, nu2 and sigma parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathProbabilityDensityNoncentralF(
    const double x,           // value of random variable
    const double nu1,         // the first parameter of distribution (number of degrees of freedom)
    const double nu2,         // the second parameter of distribution (number of degrees of freedom)
    const double sigma,       // noncentrality parameter
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability density function of noncentral Fisher's F-distribution with the nu1, nu2 and sigma parameters for an array of random variables x[]. In case of error it returns false. Analog of the [df\(\)](#) in R.

```
bool MathProbabilityDensityNoncentralF(
    const double& x[],        // array with the values of random variable
    const double nu1,         // the first parameter of distribution (number of degrees of freedom)
    const double nu2,         // the second parameter of distribution (number of degrees of freedom)
    const double sigma,       // noncentrality parameter
    const bool log_mode,      // flag to calculate the logarithm of the value, if log_mode=true
    double& result[]         // array for values of the probability density function
);
```

Calculates the value of the probability density function of noncentral Fisher's F-distribution with the nu1, nu2 and sigma parameters for an array of random variables x[]. In case of error it returns false.

```
bool MathProbabilityDensityNoncentralF(
    const double& x[],        // array with the values of random variable
    const double nu1,         // the first parameter of distribution (number of degrees of freedom)
    const double nu2,         // the second parameter of distribution (number of degrees of freedom)
    const double sigma,       // noncentrality parameter
    double& result[]         // array for values of the probability density function
);
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

nu1

[in] The first parameter of distribution (number of degrees of freedom).

nu2

[in] The second parameter of distribution (number of degrees of freedom).

sigma

[in] Noncentrality parameter.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

MathCumulativeDistributionNoncentralF

Calculates the value of the probability distribution function of noncentral Fisher's F-distribution with the nu1, nu2 and sigma parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionNoncentralF(
    const double x,           // value of random variable
    const double nu1,         // the first parameter of distribution (number of degrees of freedom)
    const double nu2,         // the second parameter of distribution (number of degrees of freedom)
    const double sigma,       // noncentrality parameter
    const bool tail,          // flag of calculation, if true, then the probability of exceeding the value is calculated
    const bool log_mode,      // flag to calculate the logarithm of the value, if true, then the logarithm is calculated
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability distribution function of noncentral Fisher's F-distribution with the nu1, nu2 and sigma parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionNoncentralF(
    const double x,           // value of random variable
    const double nu1,         // the first parameter of distribution (number of degrees of freedom)
    const double nu2,         // the second parameter of distribution (number of degrees of freedom)
    const double sigma,       // noncentrality parameter
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability distribution function of noncentral Fisher's F-distribution with the nu1, nu2 and sigma parameters for an array of random variables x[]. In case of error it returns false. Analog of the [pf\(\)](#) in R.

```
bool MathCumulativeDistributionNoncentralF(
    const double& x[],        // array with the values of random variable
    const double nu1,         // the first parameter of distribution (number of degrees of freedom)
    const double nu2,         // the second parameter of distribution (number of degrees of freedom)
    const double sigma,       // noncentrality parameter
    const bool tail,          // flag of calculation, if true, then the probability of exceeding the value is calculated
    const bool log_mode,      // flag to calculate the logarithm of the value, if true, then the logarithm is calculated
    double& result[]          // array for values of the probability function
);
```

Calculates the value of the probability distribution function of noncentral Fisher's F-distribution with the nu1, nu2 and sigma parameters for an array of random variables x[]. In case of error it returns false.

```
bool MathCumulativeDistributionNoncentralF(
    const double& x[],        // array with the values of random variable
    const double nu1,         // the first parameter of distribution (number of degrees of freedom)
    const double nu2,         // the second parameter of distribution (number of degrees of freedom)
    const double sigma,       // noncentrality parameter
    double& result[]          // array for values of the probability function
);
```

```
);
```

Parameters*x*

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

nu1

[in] The first parameter of distribution (number of degrees of freedom).

nu2

[in] The second parameter of distribution (number of degrees of freedom).

sigma

[in] Noncentrality parameter.

tail

[in] Flag of calculation. If true, then the probability of random variable not exceeding *x* is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If *log_mode*=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

MathQuantileF

For the specified *probability*, the function calculates the value of inverse noncentral Fisher's F-distribution function with the nu1, nu2 and sigma parameters. In case of error it returns [NaN](#).

```
double MathQuantileF(
    const double probability, // probability value of random variable occurrence
    const double nu1,        // the first parameter of distribution (number of de
    const double nu2,        // the second parameter of distribution (number of de
    const double sigma,      // noncentrality parameter
    const bool tail,         // flag of calculation, if false, then calculation is
    const bool log_mode,     // flag of calculation, if log_mode=true, calculation
    int& error_code          // variable to store the error code
);
```

For the specified *probability*, the function calculates the value of inverse noncentral Fisher's F-distribution function with the nu1, nu2 and sigma parameters. In case of error it returns [NaN](#).

```
double MathQuantileF(
    const double probability, // probability value of random variable occurrence
    const double nu1,        // the first parameter of distribution (number of de
    const double nu2,        // the second parameter of distribution (number of de
    const double sigma,      // noncentrality parameter
    int& error_code          // variable to store the error code
);
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse noncentral Fisher's F-distribution function with the nu1, nu2 and sigma parameters. In case of error it returns false. Analog of the [qf\(\)](#) in R.

```
double MathQuantileF(
    const double& probability[], // array with probability values of random variable
    const double nu1,           // the first parameter of distribution (number of de
    const double nu2,           // the second parameter of distribution (number of de
    const double sigma,         // noncentrality parameter
    const bool tail,            // flag of calculation, if false, then calculation is
    const bool log_mode,        // flag of calculation, if log_mode=true, calculation
    double& result[]            // array with values of quantiles
);
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse noncentral Fisher's F-distribution function with the nu1, nu2 and sigma parameters. In case of error it returns false.

```
bool MathQuantileF(
    const double& probability[], // array with probability values of random variable
    const double nu1,           // the first parameter of distribution (number of de
    const double nu2,           // the second parameter of distribution (number of de
    double& result[]            // array with values of quantiles
);
```

Parameters*probability*

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

nu1

[in] The first parameter of distribution (number of degrees of freedom).

nu2

[in] The second parameter of distribution (number of degrees of freedom).

sigma

[in] Noncentrality parameter.

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

MathRandomNoncentralF

Generates a pseudorandom variable distributed according to the law of noncentral Fisher's F-distribution with the *nu1*, *nu2* and *sigma* parameters. In case of error it returns [NaN](#).

```
double MathRandomNoncentralF(  
    const double nu1,           // the first parameter of distribution (number of de  
    const double nu2,           // the second parameter of distribution (number of de  
    const double sigma,         // noncentrality parameter  
    int& error_code              // variable to store the error code  
);
```

Generates pseudorandom variables distributed according to the law of noncentral Fisher's F-distribution with the *nu1*, *nu2* and *sigma* parameters. In case of error it returns false. Analog of the [rf\(\)](#) in R.

```
bool MathRandomNoncentralF(  
    const double nu1,           // the first parameter of distribution (number of de  
    const double nu2,           // the second parameter of distribution (number of de  
    const double sigma,         // noncentrality parameter  
    const int data_count,       // amount of required data  
    double& result[]            // array with values of pseudorandom variables  
);
```

Parameters

nu1

[in] The first parameter of distribution (number of degrees of freedom).

nu2

[in] The second parameter of distribution (number of degrees of freedom).

sigma

[in] Noncentrality parameter.

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

MathMomentsNoncentralF

Calculates the theoretical numerical values of the first 4 moments of the noncentral Fisher's F-distribution with the nu1, nu2 and sigma parameters.

```
double MathMomentsNoncentralF(  
    const double  nu1,           // the first parameter of distribution (number of de  
    const double  nu2,           // the second parameter of distribution (number of de  
    const double  sigma,         // noncentrality parameter  
    double&       mean,          // variable for the mean  
    double&       variance,      // variable for the variance  
    double&       skewness,      // variable for the skewness  
    double&       kurtosis,      // variable for the kurtosis  
    int&          error_code     // variable for the error code  
);
```

Parameters

nu1

[in] The first parameter of distribution (number of degrees of freedom).

nu2

[in] The second parameter of distribution (number of degrees of freedom).

sigma

[in] Noncentrality parameter.

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

t-distribution

This section contains functions for working with Student's t-distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the Student's law. The t-distribution is defined by the following formula:

$$f_T(x|\nu) = \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} \frac{1}{\sqrt{\pi\nu}} \frac{1}{\left(1+\frac{x^2}{\nu}\right)^{\frac{\nu+1}{2}}}$$

where:

- x — value of the random variable
- ν — parameter of distribution (number of degrees of freedom)

In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityT	Calculates the probability density function of the t-distribution
MathCumulativeDistributionT	Calculates the value of the t-distribution function
MathQuantileT	Calculates the value of the inverse t-distribution function for the specified probability
MathRandomT	Generates a pseudorandom variable/array of pseudorandom variables distributed according

	to the law of Student's t-distribution
<u>MathMomentsT</u>	Calculates the theoretical numerical values of the first 4 moments of the Student's t-distribution

Example:

```

#include <Graphics\Graphic.mqh>
#include <Math\Stat\T.mqh>
#include <Math\Stat\Math.mqh>
#property script_show_inputs
//--- input parameters
input double nu_par=10;    // the number of degrees of freedom
//+-----+
//| Script program start function |
//+-----+
void OnStart()
{
//--- hide the price chart
    ChartSetInteger(0,CHART_SHOW,false);
//--- initialize the random number generator
    MathSrand(GetTickCount());
//--- generate a sample of the random variable
    long chart=0;
    string name="GraphicNormal";
    int n=1000000;        // the number of values in the sample
    int ncells=51;        // the number of intervals in the histogram
    double x[];           // centers of the histogram intervals
    double y[];           // the number of values from the sample falling within the int
    double data[];        // sample of random values
    double max,min;       // the maximum and minimum values in the sample
//--- obtain a sample from the Student's t-distribution
    MathRandomT(nu_par,n,data);
//--- calculate the data to plot the histogram
    CalculateHistogramArray(data,x,y,max,min,ncells);
//--- obtain the sequence boundaries and the step for plotting the theoretical curve
    double step;
    GetMaxMinStepValues(max,min,step);
    step=MathMin(step,(max-min)/ncells);
//--- obtain the theoretically calculated data at the interval of [min,max]
    double x2[];
    double y2[];
    MathSequence(min,max,step,x2);
    MathProbabilityDensityT(x2,nu_par,false,y2);
//--- set the scale
    double theor_max=y2[ArrayMaximum(y2)];
    double sample_max=y[ArrayMaximum(y)];
    double k=sample_max/theor_max;

```

```

    for(int i=0; i<ncells; i++)
        y[i]/=k;
//--- output charts

    if((maxv-minv)/stepv<10)
        stepv/=10.;
}
```

MathProbabilityDensityT

Calculates the value of the probability density function of Student's t-distribution with the *nu* parameter for a random variable *x*. In case of error it returns [NaN](#).

```
double MathProbabilityDensityT(
    const double x,           // value of random variable
    const double nu,          // parameter of distribution (number of degrees of freedom)
    const bool log_mode,      // calculate the logarithm of the value, if log_mode=true
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability density function of Student's t-distribution with the *nu* parameter for a random variable *x*. In case of error it returns [NaN](#).

```
double MathProbabilityDensityT(
    const double x,           // value of random variable
    const double nu,          // parameter of distribution (number of degrees of freedom)
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability density function of Student's t-distribution with the *nu* parameter for an array of random variables *x[]*. In case of error it returns false. Analog of the [dt\(\)](#) in R.

```
bool MathProbabilityDensityT(
    const double& x[],        // array with the values of random variable
    const double nu,          // parameter of distribution (number of degrees of freedom)
    const bool log_mode,      // flag to calculate the logarithm of the value, if log_mode=true
    double& result[]         // array for values of the probability density function
);
```

Calculates the value of the probability density function of Student's t-distribution with the *nu* parameter for an array of random variables *x[]*. In case of error it returns false.

```
bool MathProbabilityDensityT(
    const double& x[],        // array with the values of random variable
    const double nu,          // parameter of distribution (number of degrees of freedom)
    double& result[]         // array for values of the probability density function
);
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

nu

[in] Parameter of distribution (number of degrees of freedom).

log_mode

[in] Flag to calculate the logarithm of the value. If `log_mode=true`, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

MathCumulativeDistributionT

Calculates the value of the Student's t-distribution function with the nu parameter for a random variable x. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionT(
    const double x,           // value of random variable
    const double nu,          // parameter of distribution (number of degrees of freedom)
    const bool tail,          // flag of calculation, if true, then the probability of exceeding
    const bool log_mode,      // flag to calculate the logarithm of the value, if true
    int& error_code           // variable to store the error code
);
```

Calculates the value of the Student's t-distribution function with the nu parameter for a random variable x. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionT(
    const double x,           // value of random variable
    const double nu,          // parameter of distribution (number of degrees of freedom)
    int& error_code           // variable to store the error code
);
```

Calculates the value of the Student's t-distribution function with the nu parameter for an array of random variables x[]. In case of error it returns false. Analog of the [pt\(\)](#) in R.

```
bool MathCumulativeDistributionT(
    const double& x[],        // array with the values of random variable
    const double nu,          // parameter of distribution (number of degrees of freedom)
    const bool tail,          // flag of calculation, if true, then the probability of exceeding
    const bool log_mode,      // flag to calculate the logarithm of the value, if true
    double& result[]          // array for values of the probability function
);
```

Calculates the value of the Student's t-distribution function with the nu parameter for an array of random variables x[]. In case of error it returns false.

```
bool MathCumulativeDistributionT(
    const double& x[],        // array with the values of random variable
    const double nu,          // parameter of distribution (number of degrees of freedom)
    double& result[]          // array for values of the probability function
);
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

nu

[in] Parameter of distribution (number of degrees of freedom).

tail

[in] Flag of calculation. If true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

MathQuantileT

For the specified *probability*, the function calculates the value of inverse Student's t-distribution function with the *nu* parameter. In case of error it returns [NaN](#).

```
double MathQuantileT(
    const double probability, // probability value of random variable occurrence
    const double nu,         // parameter of distribution (number of degrees of fr
    const bool tail,         // flag of calculation, if false, then calculation is
    const bool log_mode,     // flag of calculation, if log_mode=true, calculation
    int& error_code          // variable to store the error code
);
```

For the specified *probability*, the function calculates the value of inverse Student's t-distribution function with the *nu* parameter. In case of error it returns [NaN](#).

```
double MathQuantileT(
    const double probability, // probability value of random variable occurrence
    const double nu,         // parameter of distribution (number of degrees of fr
    int& error_code          // variable to store the error code
);
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse Student's t-distribution function with the *nu* parameter. In case of error it returns false. Analog of the [qt\(\)](#) in R.

```
double MathQuantileT(
    const double& probability[], // array with probability values of random variable
    const double nu,            // parameter of distribution (number of degrees of fr
    const bool tail,            // flag of calculation, if false, then calculation is
    const bool log_mode,        // flag of calculation, if log_mode=true, calculation
    double& result[]            // array with values of quantiles
);
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse Student's t-distribution function with the *nu* parameter. In case of error it returns false.

```
bool MathQuantileT(
    const double& probability[], // array with probability values of random variable
    const double nu,            // parameter of distribution (number of degrees of fr
    double& result[]            // array with values of quantiles
);
```

Parameters

probability

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

nu

[in] Parameter of distribution (number of degrees of freedom).

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

MathRandomT

Generates a pseudorandom variable distributed according to the law of Student's t-distribution with the *nu* parameter. In case of error it returns [NaN](#).

```
double MathRandomT(  
    const double nu,           // parameter of distribution (number of degrees of fr  
    int& error_code           // variable to store the error code  
);
```

Generates pseudorandom variables distributed according to the law of Student's t-distribution with the *nu* parameter. In case of error it returns false. Analog of the [rt\(\)](#) in R.

```
bool MathRandomT(  
    const double nu,           // parameter of distribution (number of degrees of fr  
    const int data_count,      // amount of required data  
    double& result[]          // array with values of pseudorandom variables  
);
```

Parameters

nu

[in] Parameter of distribution (number of degrees of freedom).

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

MathMomentsT

Calculates the theoretical numerical values of the first 4 moments of the Student's t-distribution with the *nu* parameter.

```
double MathMomentsT(  
    const double  nu,           // parameter of distribution (number of degrees of fr  
    double&       mean,         // variable for the mean  
    double&       variance,     // variable for the variance  
    double&       skewness,     // variable for the skewness  
    double&       kurtosis,     // variable for the kurtosis  
    int&          error_code    // variable for the error code  
);
```

Parameters

nu

[in] Parameter of distribution (number of degrees of freedom).

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

t-distribution

This section contains functions for working with noncentral Student's t-distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the law of noncentral t-distribution. The noncentral t-distribution is defined by the following formula:

$$f_{NoncentralT}(x | \nu, \delta) = \frac{\nu^{\frac{\nu}{2}} e^{-\frac{\delta^2}{2}}}{\Gamma\left(\frac{\nu}{2}\right) \sqrt{\pi} (\nu + x^2)^{\frac{\nu+1}{2}}} \sum_{r=0}^{\infty} \frac{(x\delta)^r}{r!} \left(\frac{2}{\nu + x^2}\right)^{\frac{r}{2}} \Gamma\left(\frac{\nu+r+1}{2}\right)$$

where:

- x — value of the random variable
- ν — parameter of distribution (number of degrees of freedom)
- δ — noncentrality parameter

In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
<u>MathProbabilityDensityNoncentralT</u>	Calculates the probability density function of the noncentral t-distribution
<u>MathCumulativeDistributionNoncentralT</u>	Calculates the value of the noncentral t-distribution function
<u>MathQuantileNoncentralT</u>	Calculates the value of the inverse noncentral t-distribution function for the specified probability
<u>MathRandomNoncentralT</u>	Generates a pseudorandom variable/array of pseudorandom variables distributed according

	to the noncentral Student's t-distribution law
<u>MathMomentsNoncentralT</u>	Calculates the theoretical numerical values of the first 4 moments of the noncentral Student's t-distribution

Example:

```

#include <Graphics\Graphic.mqh>

    }
```

MathProbabilityDensityNoncentralT

Calculates the value of the probability density function of noncentral Student's t-distribution with the nu and delta parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathProbabilityDensityNoncentralT(
    const double x,           // value of random variable
    const double nu,          // parameter of distribution (number of degrees of freedom)
    const double delta,       // noncentrality parameter
    const bool log_mode,      // calculate the logarithm of the value, if log_mode=true
    int& error_code           // variable for the error code
);
```

Calculates the value of the probability density function of noncentral Student's t-distribution with the nu and delta parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathProbabilityDensityNoncentralT(
    const double x,           // value of random variable
    const double nu,          // parameter of distribution (number of degrees of freedom)
    const double delta,       // noncentrality parameter
    int& error_code           // variable for the error code
);
```

Calculates the value of the probability density function of noncentral Student's t-distribution with the nu and delta parameters for an array of random variables x[]. In case of error it returns false. Analog of the [dt\(\)](#) in R.

```
bool MathProbabilityDensityNoncentralT(
    const double& x[],        // array with the values of random variable
    const double nu,          // parameter of distribution (number of degrees of freedom)
    const double delta,       // noncentrality parameter
    const bool log_mode,      // flag to calculate the logarithm of the value, if log_mode=true
    double& result[]         // array for values of the probability density function
);
```

Calculates the value of the probability density function of noncentral Student's t-distribution with the nu and delta parameters for an array of random variables x[]. In case of error it returns false.

```
bool MathProbabilityDensityNoncentralT(
    const double& x[],        // array with the values of random variable
    const double nu,          // parameter of distribution (number of degrees of freedom)
    const double delta,       // noncentrality parameter
    double& result[]         // array for values of the probability density function
);
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

nu

[in] Parameter of distribution (number of degrees of freedom).

delta

[in] Noncentrality parameter.

log_mode

[in] Flag to calculate the logarithm of the value. If `log_mode=true`, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

MathCumulativeDistributionNoncentralT

Calculates the probability distribution function of noncentral Student's t-distribution with the nu and delta parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionNoncentralT(
    const double x,           // value of random variable
    const double nu,          // parameter of distribution (number of degrees of freedom)
    const double delta,       // noncentrality parameter
    const bool tail,          // flag of calculation, if true, then the probability of exceeding
    const bool log_mode,      // flag to calculate the logarithm of the value, if true
    int& error_code           // variable to store the error code
);
```

Calculates the probability distribution function of noncentral Student's t-distribution with the nu and delta parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionNoncentralT(
    const double x,           // value of random variable
    const double nu,          // parameter of distribution (number of degrees of freedom)
    const double delta,       // noncentrality parameter
    int& error_code           // variable to store the error code
);
```

Calculates the probability distribution function of noncentral Student's t-distribution with the nu and delta parameters for an array of random variables x[]. In case of error it returns false. Analog of the [pt\(\)](#) in R.

```
bool MathCumulativeDistributionNoncentralT(
    const double& x[],        // array with the values of random variable
    const double nu,          // parameter of distribution (number of degrees of freedom)
    const double delta,       // noncentrality parameter
    const bool tail,          // flag of calculation, if true, then the probability of exceeding
    const bool log_mode,      // flag to calculate the logarithm of the value, if true
    double& result[]          // array for values of the probability function
);
```

Calculates the probability distribution function of noncentral Student's t-distribution with the nu and delta parameters for an array of random variables x[]. In case of error it returns false.

```
bool MathCumulativeDistributionNoncentralT(
    const double& x[],        // array with the values of random variable
    const double nu,          // parameter of distribution (number of degrees of freedom)
    const double delta,       // noncentrality parameter
    double& result[]          // array for values of the probability function
);
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

nu

[in] Parameter of distribution (number of degrees of freedom).

delta

[in] Noncentrality parameter.

tail

[in] Flag of calculation. If true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

MathQuantileNoncentralT

For the specified *probability*, the function calculates the value of inverse noncentral Student's t-distribution function with the *nu* and *delta* parameters. In case of error it returns [NaN](#).

```
double MathQuantileNoncentralT(
    const double probability, // probability value of random variable occurrence
    const double nu,         // parameter of distribution (number of degrees of fr
    const double delta,      // noncentrality parameter
    const bool tail,         // flag of calculation, if lower_tail=false, then cal
    const bool log_mode,     // flag of calculation, if log_mode=true, calculation
    int& error_code          // variable to store the error code
);
```

For the specified *probability*, the function calculates the value of inverse noncentral Student's t-distribution function with the *nu* and *delta* parameters. In case of error it returns [NaN](#).

```
double MathQuantileNoncentralT(
    const double probability, // probability value of random variable occurrence
    const double nu,         // parameter of distribution (number of degrees of fr
    const double delta,      // noncentrality parameter
    int& error_code          // variable to store the error code
);
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse noncentral Student's t-distribution function with the *nu* and *delta* parameters. In case of error it returns false. Analog of the [qt\(\)](#) in R.

```
double MathQuantileNoncentralT(
    const double& probability[], // array with probability values of random variable
    const double nu,            // parameter of distribution (number of degrees of fr
    const double delta,         // noncentrality parameter
    const bool tail,           // flag of calculation, if lower_tail=false, then cal
    const bool log_mode,       // flag of calculation, if log_mode=true, calculation
    double& result[]           // array with values of quantiles
);
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse noncentral Student's t-distribution function with the *nu* and *delta* parameters. In case of error it returns false.

```
bool MathQuantileNoncentralT(
    const double& probability[], // array with probability values of random variable
    const double nu,            // parameter of distribution (number of degrees of fr
    const double delta,         // noncentrality parameter
    double& result[]           // array with values of quantiles
);
```

Parameters

probability

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

nu

[in] Parameter of distribution (number of degrees of freedom).

delta

[in] Noncentrality parameter.

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

MathRandomNoncentralT

Generates a pseudorandom variable distributed according to the law of noncentral Student's t-distribution with the *nu* and *delta* parameters. In case of error it returns [NaN](#).

```
double MathRandomNoncentralT(  
    const double nu,           // parameter of distribution (number of degrees of freedom)  
    const double delta,        // noncentrality parameter  
    int& error_code            // variable to store the error code  
);
```

Generates pseudorandom variables distributed according to the law of noncentral Student's t-distribution with the *nu* and *delta* parameters. In case of error it returns false. Analog of the [rt\(\)](#) in R.

```
bool MathRandomNoncentralT(  
    const double nu,           // parameter of distribution (number of degrees of freedom)  
    const double delta,        // noncentrality parameter  
    const int data_count,      // amount of required data  
    double& result[]           // array with values of pseudorandom variables  
);
```

Parameters

nu

[in] Parameter of distribution (number of degrees of freedom).

delta

[in] Noncentrality parameter.

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

MathMomentsNoncentralT

Calculates the theoretical numerical values of the first 4 moments of the noncentral Student's t-distribution with the nu and delta parameters.

```
double MathMomentsNoncentralT(  
    const double nu,           // parameter of distribution (number of degrees of freedom)  
    const double delta,        // noncentrality parameter  
    double& mean,              // variable for the mean  
    double& variance,          // variable for the variance  
    double& skewness,          // variable for the skewness  
    double& kurtosis,          // variable for the kurtosis  
    int& error_code            // variable for the error code  
);
```

Parameters

nu

[in] Parameter of distribution (number of degrees of freedom).

delta

[in] Noncentrality parameter.

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

Logistic distribution

This section contains functions for working with logistic distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the logistic law. The logistic distribution is defined by the following formula:

$$f_{Logistic}(x|\mu,\sigma)=\frac{e^{-\frac{x-\mu}{\sigma}}}{\sigma\left(1+e^{-\frac{x-\mu}{\sigma}}\right)^2}$$

where:

- x — value of the random variable
- μ — mean parameter of the distribution
- σ — scale parameter of the distribution

In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityLogistic	Calculates the probability density function of the logistic distribution
MathCumulativeDistributionLogistic	Calculates the value of the logistic probability distribution function
MathQuantileLogistic	Calculates the value of the inverse logistic distribution function for the specified probability
MathRandomLogistic	Generates a pseudorandom variable/array of pseudorandom variables distributed according

	to the logistic law
<u>MathMomentsLogistic</u>	Calculates the theoretical numerical values of the first 4 moments of the logistic distribution

Example:

```

#include <Graphics\Graphic.mqh>
#include <Math\Stat\Logistic.mqh>
#include <Math\Stat\Math.mqh>
#property script_show_inputs
//--- input parameters
input double mu_par=6;          // mean parameter of the distribution
input double sigma_par=2;       // scale parameter of the distribution
//+-----+
//| Script program start function |
//+-----+
void OnStart()
{
//--- hide the price chart
    ChartSetInteger(0, CHART_SHOW, false);
//--- initialize the random number generator
    MathSrand(GetTickCount());
//--- generate a sample of the random variable
    long chart=0;
    string name="GraphicNormal";
    int n=1000000;           // the number of values in the sample
    int ncells=51;          // the number of intervals in the histogram
    double x[];             // centers of the histogram intervals
    double y[];             // the number of values from the sample falling within the int
    double data[];          // sample of random values
    double max,min;         // the maximum and minimum values in the sample
//--- obtain a sample from the logistic distribution
    MathRandomLogistic(mu_par, sigma_par, n, data);
//--- calculate the data to plot the histogram
    CalculateHistogramArray(data, x, y, max, min, ncells);
//--- obtain the sequence boundaries and the step for plotting the theoretical curve
    double step;
    GetMaxMinStepValues(max, min, step);
    step=MathMin(step, (max-min)/ncells);
//--- obtain the theoretically calculated data at the interval of [min,max]
    double x2[];
    double y2[];
    MathSequence(min, max, step, x2);
    MathProbabilityDensityLogistic(x2, mu_par, sigma_par, false, y2);
//--- set the scale
    double theor_max=y2[ArrayMaximum(y2)];
    double sample_max=y[ArrayMaximum(y)];
    double k=sample_max/theor_max;

```

```

    for(int i=0; i<ncells; i++)
        y[i]/=k;
//--- output charts
CGraphic graphic;
if(ObjectFind(chart,name)<0)
    graphic.Create(chart,name,0,0,0,780,380);
else

    if ((maxv-minv)/stepv<10)
        stepv/=10.;
}
```

MathProbabilityDensityLogistic

Calculates the value of the probability density function of logistic distribution with the mu and sigma parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathProbabilityDensityLogistic(
    const double x,           // value of random variable
    const double mu,          // mean parameter of the distribution
    const double sigma,       // scale parameter of the distribution
    const bool log_mode,      // calculate the logarithm of the value, if log_mode=true
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability density function of logistic distribution with the mu and sigma parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathProbabilityDensityLogistic(
    const double x,           // value of random variable
    const double mu,          // mean parameter of the distribution
    const double sigma,       // scale parameter of the distribution
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability density function of logistic distribution with the mu and sigma parameters for an array of random variables x[]. In case of error it returns false. Analog of the [dlogis\(\)](#) in R.

```
bool MathProbabilityDensityLogistic(
    const double& x[],         // array with the values of random variable
    const double mu,           // mean parameter of the distribution
    const double sigma,        // scale parameter of the distribution
    const bool log_mode,       // flag to calculate the logarithm of the value, if log_mode=true
    double& result[]           // array for values of the probability density function
);
```

Calculates the value of the probability density function of logistic distribution with the mu and sigma parameters for an array of random variables x[]. In case of error it returns false.

```
bool MathProbabilityDensityLogistic(
    const double& x[],         // array with the values of random variable
    const double mu,           // mean parameter of the distribution
    const double sigma,        // scale parameter of the distribution
    double& result[]           // array for values of the probability density function
);
```

Parameters

x
[in] Value of random variable.

x[]

[in] Array with the values of random variable.

mu

[in] mean parameter of the distribution.

sigma

[in] scale parameter of the distribution.

log_mode

[in] Flag to calculate the logarithm of the value. If `log_mode=true`, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

MathCumulativeDistributionLogistic

Calculates the logistic distribution function of probabilities with the mu and sigma parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionLogistic(
    const double x,           // value of random variable
    const double mu,          // mean parameter of the distribution
    const double sigma,       // scale parameter of the distribution
    const bool tail,          // flag of calculation, if true, then the probability
    const bool log_mode,      // flag to calculate the logarithm of the value, if 1
    int& error_code           // variable to store the error code
);
```

Calculates the logistic distribution function of probabilities with the mu and sigma parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionLogistic(
    const double x,           // value of random variable
    const double mu,          // mean parameter of the distribution
    const double sigma,       // scale parameter of the distribution
    int& error_code           // variable to store the error code
);
```

Calculates the logistic distribution function of probabilities with the mu and sigma parameters for an array of random variables x[]. In case of error it returns false.

```
bool MathCumulativeDistributionLogistic(
    const double& x[],        // array with the values of random variable
    const double mu,          // mean parameter of the distribution
    const double sigma,       // scale parameter of the distribution
    const bool tail,          // flag of calculation, if true, then the probability
    const bool log_mode,      // flag to calculate the logarithm of the value, if 1
    double& result[]          // array for values of the probability function
);
```

Calculates the logistic distribution function of probabilities with the mu and sigma parameters for an array of random variables x[]. In case of error it returns false. Analog of the [plogis\(\)](#) in R.

```
bool MathCumulativeDistributionLogistic(
    const double& x[],        // array with the values of random variable
    const double mu,          // mean parameter of the distribution
    const double sigma,       // scale parameter of the distribution
    double& result[]          // array for values of the probability function
);
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

mu

[in] mean parameter of the distribution.

sigma

[in] scale parameter of the distribution.

tail

[in] Flag of calculation. If true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

MathQuantileLogistic

For the specified *probability*, the function calculates the value of inverse logistic distribution function with the mu and sigma parameters. In case of error it returns [NaN](#).

```
double MathQuantileLogistic(
    const double probability, // probability value of random variable occurrence
    const double mu,         // mean parameter of the distribution
    const double sigma,      // scale parameter of the distribution
    const bool tail,         // flag of calculation, if false, then calculation is
    const bool log_mode,     // flag of calculation, if log_mode=true, calculation
    int& error_code          // variable to store the error code
);
```

For the specified *probability*, the function calculates the value of inverse logistic distribution function with the mu and sigma parameters. In case of error it returns [NaN](#).

```
double MathQuantileLogistic(
    const double probability, // probability value of random variable occurrence
    const double mu,         // mean parameter of the distribution
    const double sigma,      // scale parameter of the distribution
    int& error_code          // variable to store the error code
);
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse logistic distribution function with the mu and sigma parameters. In case of error it returns false. Analog of the [qlogis\(\)](#) in R.

```
double MathQuantileLogistic(
    const double& probability[], // array with probability values of random variable
    const double mu,            // mean parameter of the distribution
    const double sigma,         // scale parameter of the distribution
    const bool tail,           // flag of calculation, if false, then calculation is
    const bool log_mode,       // flag of calculation, if log_mode=true, calculation
    double& result[]           // array with values of quantiles
);
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse logistic distribution function with the mu and sigma parameters. In case of error it returns false.

```
bool MathQuantileLogistic(
    const double& probability[], // array with probability values of random variable
    const double mu,            // mean parameter of the distribution
    const double sigma,         // scale parameter of the distribution
    double& result[]           // array with values of quantiles
);
```

Parameters

probability

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

mu

[in] mean parameter of the distribution.

sigma

[in] scale parameter of the distribution.

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

MathRandomLogistic

Generates a pseudorandom variable distributed according to the law of logistic distribution with the μ and σ parameters. In case of error it returns [NaN](#).

```
double MathRandomLogistic(  
    const double mu,           // mean parameter of the distribution  
    const double sigma,        // scale parameter of the distribution  
    int& error_code             // variable to store the error code  
);
```

Generates pseudorandom variables distributed according to the law of logistic distribution with the μ and σ parameters. In case of error it returns false. Analog of the [rlogis\(\)](#) in R.

```
bool MathRandomLogistic(  
    const double mu,           // mean parameter of the distribution  
    const double sigma,        // scale parameter of the distribution  
    const int data_count,      // amount of required data  
    double& result[]           // array with values of pseudorandom variables  
);
```

Parameters

mu

[in] mean parameter of the distribution.

sigma

[in] scale parameter of the distribution.

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

MathMomentsLogistic

Calculates the theoretical numerical values of the first 4 moments of the logistic distribution with the μ and σ parameters.

```
double MathMomentsLogistic(  
    const double mu,           // mean parameter of the distribution  
    const double sigma,       // scale parameter of the distribution  
    double& mean,             // variable for the mean  
    double& variance,         // variable for the variance  
    double& skewness,         // variable for the skewness  
    double& kurtosis,         // variable for the kurtosis  
    int& error_code           // variable for the error code  
);
```

Parameters

mu

[in] mean parameter of the distribution.

sigma

[in] scale parameter of the distribution.

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

Cauchy distribution

This section contains functions for working with Cauchy distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the Cauchy law. The Cauchy distribution is defined by the following formula:

$$f_{Cauchy}(x|a,b) = \frac{1}{\pi} \frac{b}{b^2 + (x-a)^2}$$

where:

- x – value of the random variable
- a – mean parameter of the distribution
- b – scale parameter of the distribution

In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityCauchy	Calculates the probability density function of the Cauchy distribution
MathCumulativeDistributionCauchy	Calculates the value of the Cauchy probability distribution function
MathQuantileCauchy	Calculates the value of the inverse Cauchy distribution function for the specified probability
MathRandomCauchy	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the Cauchy law

MathMomentsCauchy

Calculates the theoretical numerical values of the first 4 moments of the Cauchy distribution

Example:

```
#include <Graphics\Graphic.mqh>
#include <Math\Stat\Cauchy.mqh>
#include <Math\Stat\Math.mqh>
#property script_show_inputs
//--- input parameters
input double a_par=-2;      // mean parameter of the distribution
input double b_par=1;      // scale parameter of the distribution
//+-----+
//| Script program start function |
//+-----+
void OnStart()
{
//--- hide the price chart
    ChartSetInteger(0,CHART_SHOW,false);
//--- initialize the random number generator
    MathSrand(GetTickCount());
//--- generate a sample of the random variable
    long chart=0;
    string name="GraphicNormal";
    int n=1000000;          // the number of values in the sample
    int ncells=51;          // the number of intervals in the histogram
    double x[];             // centers of the histogram intervals
    double y[];             // the number of values from the sample falling within the int
    double data[];          // sample of random values
    double max,min;         // the maximum and minimum values in the sample
//--- obtain a sample from the Cauchy distribution
    MathRandomCauchy(a_par,b_par,n,data);
//--- calculate the data to plot the histogram
    CalculateHistogramArray(data,x,y,max,min,ncells);
//--- obtain the sequence boundaries and the step for plotting the theoretical curve
    double step;
    GetMaxMinStepValues(max,min,step);
    step=MathMin(step,(max-min)/ncells);
//--- obtain the theoretically calculated data at the interval of [min,max]
    double x2[];
    double y2[];
    MathSequence(min,max,step,x2);
    MathProbabilityDensityCauchy(x2,a_par,b_par,false,y2);
//--- set the scale
    double theor_max=y2[ArrayMaximum(y2)];
    double sample_max=y[ArrayMaximum(y)];
    double k=sample_max/theor_max;
    for(int i=0; i<ncells; i++)
```

```

        y[i]/=k;
//--- output charts
CGraphic graphic;
if(ObjectFind(chart,name)<0)
    graphic.Create(chart,name,0,0,0,780,380);
else
    graphic.Attach(chart,name);

    if((maxv-minv)/stepv<10)
        stepv/=10.;
}
```

MathProbabilityDensityCauchy

Calculates the value of the probability density function of Cauchy distribution with the a and b parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathProbabilityDensityCauchy(
    const double x,           // value of random variable
    const double a,           // mean parameter of the distribution
    const double b,           // scale parameter of the distribution
    const bool log_mode,      // calculate the logarithm of the value, if log_mode=true
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability density function of Cauchy distribution with the a and b parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathProbabilityDensityCauchy(
    const double x,           // value of random variable
    const double a,           // mean parameter of the distribution
    const double b,           // scale parameter of the distribution
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability density function of Cauchy distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false. Analog of the [dcauchy\(\)](#) in R.

```
bool MathProbabilityDensityCauchy(
    const double& x[],        // array with the values of random variable
    const double a,           // mean parameter of the distribution
    const double b,           // scale parameter of the distribution
    const bool log_mode,      // flag to calculate the logarithm of the value, if log_mode=true
    double& result[]          // array for values of the probability density function
);
```

Calculates the value of the probability density function of Cauchy distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false.

```
bool MathProbabilityDensityCauchy(
    const double& x[],        // array with the values of random variable
    const double a,           // mean parameter of the distribution
    const double b,           // scale parameter of the distribution
    double& result[]          // array for values of the probability density function
);
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

a

[in] mean parameter of the distribution.

b

[in] scale parameter of the distribution.

log_mode

[in] Flag to calculate the logarithm of the value. If `log_mode=true`, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

MathCumulativeDistributionCauchy

Calculates the probability distribution function of Cauchy distribution with the a and b parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionCauchy(
    const double x,           // value of random variable
    const double a,           // mean parameter of the distribution
    const double b,           // scale parameter of the distribution
    const bool tail,          // flag of calculation, if true, then the probability
    const bool log_mode,      // flag to calculate the logarithm of the value, if 1
    int& error_code           // variable to store the error code
);
```

Calculates the probability distribution function of Cauchy distribution with the a and b parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionCauchy(
    const double x,           // value of random variable
    const double a,           // mean parameter of the distribution
    const double b,           // scale parameter of the distribution
    int& error_code           // variable to store the error code
);
```

Calculates the probability distribution function of Cauchy distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false.

```
bool MathCumulativeDistributionCauchy(
    const double& x[],        // array with the values of random variable
    const double a,           // mean parameter of the distribution
    const double b,           // scale parameter of the distribution
    const bool tail,          // flag of calculation, if true, then the probability
    const bool log_mode,      // flag to calculate the logarithm of the value, if 1
    double& result[]          // array for values of the probability function
);
```

Calculates the probability distribution function of Cauchy distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false. Analog of the [plogis\(\)](#) in R.

```
bool MathCumulativeDistributionCauchy(
    const double& x[],        // array with the values of random variable
    const double a,           // mean parameter of the distribution
    const double b,           // scale parameter of the distribution
    double& result[]          // array for values of the probability function
);
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

a

[in] mean parameter of the distribution.

b

[in] scale parameter of the distribution.

tail

[in] Flag of calculation. If true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

MathQuantileCauchy

For the specified *probability*, the function calculates the value of inverse Cauchy distribution function with the a and b parameters. In case of error it returns [NaN](#).

```
double MathQuantileCauchy(
    const double probability, // probability value of random variable occurrence
    const double a,          // mean parameter of the distribution
    const double b,          // scale parameter of the distribution
    const bool tail,         // flag of calculation, if false, then calculation is
    const bool log_mode,     // flag of calculation, if log_mode=true, calculation
    int& error_code          // variable to store the error code
);
```

For the specified *probability*, the function calculates the value of inverse Cauchy distribution function with the a and b parameters. In case of error it returns [NaN](#).

```
double MathQuantileCauchy(
    const double probability, // probability value of random variable occurrence
    const double a,          // mean parameter of the distribution
    const double b,          // scale parameter of the distribution
    int& error_code          // variable to store the error code
);
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse Cauchy distribution function with the a and b parameters. In case of error it returns false. Analog of the [qcauchy\(\)](#) in R.

```
double MathQuantileCauchy(
    const double& probability[], // array with probability values of random variable
    const double a,              // mean parameter of the distribution
    const double b,              // scale parameter of the distribution
    const bool tail,             // flag of calculation, if false, then calculation is
    const bool log_mode,         // flag of calculation, if log_mode=true, calculation
    double& result[]            // array with values of quantiles
);
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse Cauchy distribution function with the a and b parameters. In case of error it returns false.

```
bool MathQuantileCauchy(
    const double& probability[], // array with probability values of random variable
    const double a,              // mean parameter of the distribution
    const double b,              // scale parameter of the distribution
    double& result[]            // array with values of quantiles
);
```

Parameters

probability

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

a

[in] mean parameter of the distribution.

b

[in] scale parameter of the distribution.

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

MathRandomCauchy

Generates a pseudorandom variable distributed according to the law of Cauchy distribution with the *a* and *b* parameters. In case of error it returns [NaN](#).

```
double MathRandomCauchy(  
    const double a,           // mean parameter of the distribution  
    const double b,           // scale parameter of the distribution  
    int& error_code           // variable to store the error code  
);
```

Generates pseudorandom variables distributed according to the law of Cauchy distribution with the *a* and *b* parameters. In case of error it returns false. Analog of the [rcauchy\(\)](#) in R.

```
bool MathRandomCauchy(  
    const double a,           // mean parameter of the distribution  
    const double b,           // scale parameter of the distribution  
    const int data_count,     // amount of required data  
    double& result[]          // array with values of pseudorandom variables  
);
```

Parameters

a

[in] mean parameter of the distribution.

b

[in] scale parameter of the distribution.

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

MathMomentsCauchy

Calculates the theoretical numerical values of the first 4 moments of the Cauchy distribution with the *a* and *b* parameters.

```
double MathMomentsCauchy(  
    const double a,           // mean parameter of the distribution  
    const double b,           // scale parameter of the distribution  
    double& mean,             // variable for the mean  
    double& variance,         // variable for the variance  
    double& skewness,         // variable for the skewness  
    double& kurtosis,         // variable for the kurtosis  
    int& error_code           // variable for the error code  
);
```

Parameters

a
[in] mean parameter of the distribution.

b
[in] scale parameter of the distribution.

mean
[out] Variable to get the mean value.

variance
[out] Variable to get the variance.

skewness
[out] Variable to get the skewness.

kurtosis
[out] Variable to get the kurtosis.

error_code
[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

Uniform distribution

This section contains functions for working with uniform distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the uniform law. The uniform distribution is defined by the following formula:

$$f_{Uniform}(x|a,b)=\frac{1}{b-a}$$

where:

- x – value of the random variable
- a – parameter of the distribution (lower bound)
- b – parameter of the distribution (upper bound)

In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityUniform	Calculates the probability density function of the uniform distribution
MathCumulativeDistributionUniform	Calculates the value of the uniform probability distribution function
MathQuantileUniform	Calculates the value of the inverse uniform distribution function for the specified probability
MathRandomUniform	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the uniform law

MathMomentsUniform

Calculates the theoretical numerical values of the first 4 moments of the uniform distribution

Example:

```
#include <Graphics\Graphic.mqh>
#include <Math\Stat\Uniform.mqh>
#include <Math\Stat\Math.mqh>
#property script_show_inputs
//--- input parameters
input double a_par=0;      // distribution parameter a (lower bound)
input double b_par=10;     // distribution parameter b (upper bound)
//+-----+
//| Script program start function |
//+-----+
void OnStart()
{
    //--- hide the price chart
    ChartSetInteger(0,CHART_SHOW,false);
    //--- initialize the random number generator
    MathSrand(GetTickCount());
    //--- generate a sample of the random variable
    long chart=0;
    string name="GraphicNormal";
    int n=1000000;          // the number of values in the sample
    int ncells=51;          // the number of intervals in the histogram
    double x[];             // centers of the histogram intervals
    double y[];             // the number of values from the sample falling within the int
    double data[];          // sample of random values
    double max,min;         // the maximum and minimum values in the sample
    //--- obtain a sample from the uniform distribution
    MathRandomUniform(a_par,b_par,n,data);
    //--- calculate the data to plot the histogram
    CalculateHistogramArray(data,x,y,max,min,ncells);
    //--- obtain the sequence boundaries and the step for plotting the theoretical curve
    double step;
    GetMaxMinStepValues(max,min,step);
    step=MathMin(step,(max-min)/ncells);
    //--- obtain the theoretically calculated data at the interval of [min,max]
    double x2[];
    double y2[];
    MathSequence(min,max,step,x2);
    MathProbabilityDensityUniform(x2,a_par,b_par,false,y2);
    //--- set the scale
    double theor_max=y2[ArrayMaximum(y2)];
    double sample_max=y[ArrayMaximum(y)];
    double k=sample_max/theor_max;
    for(int i=0; i<ncells; i++)
```

```

        y[i]/=k;
//--- output charts
        CGraphic graphic;
        if(ObjectFind(chart,name)<0)

//--- calculate the absolute range of the sequence to obtain the precision of normalization
    double range=MathAbs(maxv-minv);
    int degree=(int)MathRound(MathLog10(range));
//--- normalize the maximum and minimum values to the specified precision
    maxv=NormalizeDouble(maxv, degree);
    minv=NormalizeDouble(minv, degree);
//--- sequence generation step is also set based on the specified precision
    stepv=NormalizeDouble(MathPow(10, -degree), degree);
    if((maxv-minv)/stepv<10)
        stepv/=10.;
}
```

MathProbabilityDensityUniform

Calculates the value of the probability density function of uniform distribution with the a and b parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathProbabilityDensityUniform(
    const double x,           // value of random variable
    const double a,           // distribution parameter a (lower bound)
    const double b,           // distribution parameter b (upper bound)
    const bool log_mode,      // calculate the logarithm of the value, if log_mode=true
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability density function of uniform distribution with the a and b parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathProbabilityDensityUniform(
    const double x,           // value of random variable
    const double a,           // distribution parameter a (lower bound)
    const double b,           // distribution parameter b (upper bound)
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability density function of uniform distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false. Analog of the [dunif\(\)](#) in R.

```
bool MathProbabilityDensityUniform(
    const double& x[],        // array with the values of random variable
    const double a,           // distribution parameter a (lower bound)
    const double b,           // distribution parameter b (upper bound)
    const bool log_mode,      // flag to calculate the logarithm of the value, if log_mode=true
    double& result[]         // array for values of the probability density function
);
```

Calculates the value of the probability density function of uniform distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false.

```
bool MathProbabilityDensityUniform(
    const double& x[],        // array with the values of random variable
    const double a,           // distribution parameter a (lower bound)
    const double b,           // distribution parameter b (upper bound)
    double& result[]         // array for values of the probability density function
);
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

a

[in] Distribution parameter a (lower bound).

b

[in] Distribution parameter b (upper bound).

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

MathCumulativeDistributionUniform

Calculates the probability distribution function of uniform distribution with the a and b parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionUniform(
    const double x,           // value of random variable
    const double a,           // distribution parameter a (lower bound)
    const double b,           // distribution parameter b (upper bound)
    const bool tail,          // flag of calculation, if true, then the probability
    const bool log_mode,      // flag to calculate the logarithm of the value, if 1
    int& error_code           // variable to store the error code
);
```

Calculates the probability distribution function of uniform distribution with the a and b parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionUniform(
    const double x,           // value of random variable
    const double a,           // distribution parameter a (lower bound)
    const double b,           // distribution parameter b (upper bound)
    int& error_code           // variable to store the error code
);
```

Calculates the probability distribution function of uniform distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false.

```
bool MathCumulativeDistributionUniform(
    const double& x[],        // array with the values of random variable
    const double a,           // distribution parameter a (lower bound)
    const double b,           // distribution parameter b (upper bound)
    const bool tail,          // flag of calculation, if true, then the probability
    const bool log_mode,      // flag to calculate the logarithm of the value, if 1
    double& result[]          // array for values of the probability function
);
```

Calculates the probability distribution function of uniform distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false. Analog of the [punif\(\)](#) in R.

```
bool MathCumulativeDistributionUniform(
    const double& x[],        // array with the values of random variable
    const double a,           // distribution parameter a (lower bound)
    const double b,           // distribution parameter b (upper bound)
    double& result[]          // array for values of the probability function
);
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

a

[in] Distribution parameter a (lower bound).

b

[in] Distribution parameter b (upper bound).

tail

[in] Flag of calculation. If true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

MathQuantileUniform

For the specified *probability*, the function calculates the value of inverse uniform distribution function with the a and b parameters. In case of error it returns [NaN](#).

```
double MathQuantileUniform(
    const double probability, // probability value of random variable occurrence
    const double a,           // distribution parameter a (lower bound)
    const double b,           // distribution parameter b (upper bound)
    const bool tail,          // flag of calculation, if false, then calculation is
    const bool log_mode,      // flag of calculation, if log_mode=true, calculation
    int& error_code           // variable to store the error code
);
```

For the specified *probability*, the function calculates the value of inverse uniform distribution function with the a and b parameters. In case of error it returns [NaN](#).

```
double MathQuantileUniform(
    const double probability, // probability value of random variable occurrence
    const double a,           // distribution parameter a (lower bound)
    const double b,           // distribution parameter b (upper bound)
    int& error_code           // variable to store the error code
);
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse uniform distribution function with the a and b parameters. In case of error it returns false. Analog of the [qcauschy\(\)](#) in R.

```
double MathQuantileUniform(
    const double& probability[], // array with probability values of random variable
    const double a,              // distribution parameter a (lower bound)
    const double b,              // distribution parameter b (upper bound)
    const bool tail,             // flag of calculation, if false, then calculation is
    const bool log_mode,         // flag of calculation, if log_mode=true, calculation
    double& result[]             // array with values of quantiles
);
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse uniform distribution function with the a and b parameters. In case of error it returns false.

```
bool MathQuantileUniform(
    const double& probability[], // array with probability values of random variable
    const double a,              // distribution parameter a (lower bound)
    const double b,              // distribution parameter b (upper bound)
    double& result[]             // array with values of quantiles
);
```

Parameters

probability

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

a

[in] Distribution parameter a (lower bound).

b

[in] Distribution parameter b (upper bound).

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

MathRandomUniform

Generates a pseudorandom variable distributed according to the law of uniform distribution with the *a* and *b* parameters. In case of error it returns [NaN](#).

```
double MathRandomUniform(  
    const double a,           // distribution parameter a (lower bound)  
    const double b,           // distribution parameter b (upper bound)  
    int& error_code           // variable to store the error code  
);
```

Generates pseudorandom variables distributed according to the law of uniform distribution with the *a* and *b* parameters. In case of error it returns false. Analog of the [runif\(\)](#) in R.

```
bool MathRandomUniform(  
    const double a,           // distribution parameter a (lower bound)  
    const double b,           // distribution parameter b (upper bound)  
    const int data_count,     // amount of required data  
    double& result[]          // array with values of pseudorandom variables  
);
```

Parameters

a

[in] Distribution parameter *a* (lower bound).

b

[in] Distribution parameter *b* (upper bound).

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

MathMomentsUniform

Calculates the theoretical numerical values of the first 4 moments of the uniform distribution with the a and b parameters.

```
double MathMomentsUniform(  
    const double a,           // distribution parameter a (lower bound)  
    const double b,           // distribution parameter b (upper bound)  
    double& mean,             // variable for the mean  
    double& variance,         // variable for the variance  
    double& skewness,         // variable for the skewness  
    double& kurtosis,         // variable for the kurtosis  
    int& error_code           // variable for the error code  
);
```

Parameters

a

[in] Distribution parameter a (lower bound).

b

[in] Distribution parameter b (upper bound).

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

Weibull distribution

This section contains functions for working with Weibull distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the Weibull law. The Weibull distribution is defined by the following formula:

$$f_{\text{Weibull}}\left(x|a,b\right)=\frac{a}{b}\left(\frac{x}{b}\right)^{a-1}e^{-\left(\frac{x}{b}\right)^a}$$

where:

- x – value of the random variable
- a – parameter of the distribution (shape)
- b – parameter of the distribution (scale)

In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityWeibull	Calculates the probability density function of the Weibull distribution
MathCumulativeDistributionWeibull	Calculates the value of the Weibull probability distribution function
MathQuantileWeibull	Calculates the value of the inverse Weibull distribution function for the specified probability
MathRandomWeibull	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the Weibull law

MathMomentsWeibull

Calculates the theoretical numerical values of the first 4 moments of the Weibull distribution

Example:

```
#include <Graphics\Graphic.mqh>
#include <Math\Stat\Weibull.mqh>
#include <Math\Stat\Math.mqh>
#property script_show_inputs
//--- input parameters
input double a_par=1;      // parameter of the distribution (shape)
input double b_par=5;      // parameter of the distribution (scale)
//+-----+
//| Script program start function |
//+-----+
void OnStart()
{
    //--- hide the price chart
    ChartSetInteger(0,CHART_SHOW,false);
    //--- initialize the random number generator
    MathSrand(GetTickCount());
    //--- generate a sample of the random variable
    long chart=0;
    string name="GraphicNormal";
    int n=1000000;          // the number of values in the sample
    int ncells=51;          // the number of intervals in the histogram
    double x[];             // centers of the histogram intervals
    double y[];             // the number of values from the sample falling within the intervals
    double data[];          // sample of random values
    double max,min;         // the maximum and minimum values in the sample
    //--- obtain a sample from the Weibull distribution
    MathRandomWeibull(a_par,b_par,n,data);
    //--- calculate the data to plot the histogram
    CalculateHistogramArray(data,x,y,max,min,ncells);
    //--- obtain the sequence boundaries and the step for plotting the theoretical curve
    double step;
    GetMaxMinStepValues(max,min,step);
    step=MathMin(step,(max-min)/ncells);
    //--- obtain the theoretically calculated data at the interval of [min,max]
    double x2[];
    double y2[];
    MathSequence(min,max,step,x2);
    MathProbabilityDensityWeibull(x2,a_par,b_par,false,y2);
    //--- set the scale
    double theor_max=y2[ArrayMaximum(y2)];
    double sample_max=y[ArrayMaximum(y)];
    double k=sample_max/theor_max;
    for(int i=0; i<ncells; i++)
```

```

        y[i]/=k;
//--- output charts
CGraphic graphic;

    maxv=NormalizeDouble(maxv,degree);
    minv=NormalizeDouble(minv,degree);
    //--- sequence generation step is also set based on the specified precision
    stepv=NormalizeDouble(MathPow(10,-degree),degree);
    if ((maxv-minv)/stepv<10)
        stepv/=10.;
}
```

MathProbabilityDensityWeibull

Calculates the value of the probability density function of Weibull distribution with the a and b parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathProbabilityDensityWeibull(
    const double x,           // value of random variable
    const double a,           // parameter of the distribution (shape)
    const double b,           // parameter of the distribution (scale)
    const bool log_mode,      // calculate the logarithm of the value, if log_mode=true
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability density function of Weibull distribution with the a and b parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathProbabilityDensityWeibull(
    const double x,           // value of random variable
    const double a,           // parameter of the distribution (shape)
    const double b,           // parameter of the distribution (scale)
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability density function of Weibull distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false. Analog of the [dweibull\(\)](#) in R.

```
bool MathProbabilityDensityWeibull(
    const double& x[],        // array with the values of random variable
    const double a,           // parameter of the distribution (shape)
    const double b,           // parameter of the distribution (scale)
    const bool log_mode,      // flag to calculate the logarithm of the value, if log_mode=true
    double& result[]         // array for values of the probability density function
);
```

Calculates the value of the probability density function of Weibull distribution with the a and b parameters for an array of random variables x[]. In case of error it returns false.

```
bool MathProbabilityDensityWeibull(
    const double& x[],        // array with the values of random variable
    const double a,           // parameter of the distribution (shape)
    const double b,           // parameter of the distribution (scale)
    double& result[]         // array for values of the probability density function
);
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

a

[in] Parameter of the distribution (scale).

b

[in] Parameter of the distribution (shape).

log_mode

[in] Flag to calculate the logarithm of the value. If `log_mode=true`, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

MathCumulativeDistributionWeibull

Calculates the value of the Weibull distribution function with the a and b parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionWeibull(
    const double x,           // value of random variable
    const double a,           // parameter of the distribution (shape)
    const double b,           // parameter of the distribution (scale)
    const bool tail,          // flag of calculation, if true, then the probability
    const bool log_mode,      // flag to calculate the logarithm of the value, if 1
    int& error_code           // variable to store the error code
);
```

Calculates the value of the Weibull distribution function with the a and b parameters for a random variable x. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionWeibull(
    const double x,           // value of random variable
    const double a,           // parameter of the distribution (shape)
    const double b,           // parameter of the distribution (scale)
    int& error_code           // variable to store the error code
);
```

Calculates the value of the Weibull distribution function with the a and b parameters for an array of random variables x[]. In case of error it returns false. Analog of the [pweibull\(\)](#) in R.

```
bool MathCumulativeDistributionWeibull(
    const double& x[],        // array with the values of random variable
    const double a,           // parameter of the distribution (shape)
    const double b,           // parameter of the distribution (scale)
    const bool tail,          // flag of calculation, if true, then the probability
    const bool log_mode,      // flag to calculate the logarithm of the value, if 1
    double& result[]          // array for values of the probability function
);
```

Calculates the value of the Weibull distribution function with the a and b parameters for an array of random variables x[]. In case of error it returns false.

```
bool MathCumulativeDistributionWeibull(
    const double& x[],        // array with the values of random variable
    const double a,           // parameter of the distribution (shape)
    const double b,           // parameter of the distribution (scale)
    double& result[]          // array for values of the probability function
);
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

a

[in] Parameter of the distribution (scale).

b

[in] Parameter of the distribution (shape).

tail

[in] Flag of calculation. If true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

MathQuantileWeibull

For the specified *probability*, the function calculates the value of inverse Weibull distribution function with the a and b parameters. In case of error it returns [NaN](#).

```
double MathQuantileWeibull(
    const double probability, // probability value of random variable occurrence
    const double a,          // parameter of the distribution (shape)
    const double b,          // parameter of the distribution (scale)
    const bool tail,         // flag of calculation, if false, then calculation is
    const bool log_mode,     // flag of calculation, if log_mode=true, calculation
    int& error_code          // variable to store the error code
);
```

For the specified *probability*, the function calculates the value of inverse Weibull distribution function with the a and b parameters. In case of error it returns [NaN](#).

```
double MathQuantileWeibull(
    const double probability, // probability value of random variable occurrence
    const double a,          // parameter of the distribution (shape)
    const double b,          // parameter of the distribution (scale)
    int& error_code          // variable to store the error code
);
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse Weibull distribution function with the a and b parameters. In case of error it returns false. Analog of the [qweibull\(\)](#) in R.

```
double MathQuantileWeibull(
    const double& probability[], // array with probability values of random variable
    const double a,             // parameter of the distribution (shape)
    const double b,             // parameter of the distribution (scale)
    const bool tail,            // flag of calculation, if false, then calculation is
    const bool log_mode,        // flag of calculation, if log_mode=true, calculation
    double& result[]            // array with values of quantiles
);
```

For the specified *probability[]* array of probability values, the function calculates the value of inverse Weibull distribution function with the a and b parameters. In case of error it returns false.

```
bool MathQuantileWeibull(
    const double& probability[], // array with probability values of random variable
    const double a,             // parameter of the distribution (shape)
    const double b,             // parameter of the distribution (scale)
    double& result[]            // array with values of quantiles
);
```

Parameters

probability

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

a

[in] Parameter of the distribution (scale).

b

[in] Parameter of the distribution (shape).

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

MathRandomWeibull

Generates a pseudorandom variable distributed according to the law of Weibull distribution with the *a* and *b* parameters. In case of error it returns [NaN](#).

```
double MathRandomWeibull(  
    const double a,           // parameter of the distribution (shape)  
    const double b,           // parameter of the distribution (scale)  
    int& error_code           // variable to store the error code  
);
```

Generates pseudorandom variables distributed according to the law of Weibull distribution with the *a* and *b* parameters. In case of error it returns false. Analog of the [rweibull\(\)](#) in R.

```
bool MathRandomWeibull(  
    const double a,           // parameter of the distribution (shape)  
    const double b,           // parameter of the distribution (scale)  
    const int data_count,     // amount of required data  
    double& result[]          // array with values of pseudorandom variables  
);
```

Parameters

a

[in] Parameter of the distribution (scale).

b

[in] Parameter of the distribution (shape).

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

MathMomentsWeibull

Calculates the theoretical numerical values of the first 4 moments of the Weibull distribution with the *a* and *b* parameters.

```
double MathMomentsWeibull(  
    const double a,           // parameter of the distribution (shape)  
    const double b,           // parameter of the distribution (scale)  
    double& mean,             // variable for the mean  
    double& variance,         // variable for the variance  
    double& skewness,         // variable for the skewness  
    double& kurtosis,         // variable for the kurtosis  
    int& error_code           // variable for the error code  
);
```

Parameters

a

[in] Parameter of the distribution (scale).

b

[in] Parameter of the distribution (shape).

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

Binomial distribution

This section contains functions for working with binomial distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the binomial law. The binomial distribution is defined by the following formula:

$$f_{\text{Binomial}}(x|n, p) = \binom{n}{x} p^x (1 - p)^{n-x}$$

where:

- x – value of the random variable
- n – number of tests
- p – probability of success for each test

In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityBinomial	Calculates the probability density function of the binomial distribution
MathCumulativeDistributionBinomial	Calculates the value of the binomial probability distribution function
MathQuantileBinomial	Calculates the value of the inverse binomial distribution function for the specified probability
MathRandomBinomial	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the binomial law

MathMomentsBinomial

Calculates the theoretical numerical values of the first 4 moments of the binomial distribution

Example:

```
#include <Graphics\Graphic.mqh>
#include <Math\Stat\Binomial.mqh>
#include <Math\Stat\Math.mqh>
#property script_show_inputs
//--- input parameters
input double n_par=40;          // the number of tests
input double p_par=0.75;        // probability of success for each test
//+-----+
//| Script program start function |
//+-----+
void OnStart()
{
//--- hide the price chart
    ChartSetInteger(0,CHART_SHOW,false);
//--- initialize the random number generator
    MathSrand(GetTickCount());
//--- generate a sample of the random variable
    long chart=0;
    string name="GraphicNormal";
    int n=1000000;          // the number of values in the sample
    int ncells=20;          // the number of intervals in the histogram
    double x[];             // centers of the histogram intervals
    double y[];             // the number of values from the sample falling within the interval
    double data[];          // sample of random values
    double max,min;         // the maximum and minimum values in the sample
//--- obtain a sample from the binomial distribution
    MathRandomBinomial(n_par,p_par,n,data);
//--- calculate the data to plot the histogram
    CalculateHistogramArray(data,x,y,max,min,ncells);
//--- obtain the theoretically calculated data at the interval of [min,max]
    double x2[];
    double y2[];
    MathSequence(0,n_par,1,x2);
    MathProbabilityDensityBinomial(x2,n_par,p_par,false,y2);
//--- set the scale
    double theor_max=y2[ArrayMaximum(y2)];
    double sample_max=y[ArrayMaximum(y)];
    double k=sample_max/theor_max;
    for(int i=0; i<ncells; i++)
        y[i]/=k;
//--- output charts
    CGraphic graphic;
    if(ObjectFind(chart,name)<0)
```

```

        graphic.Create(chart,name,0,0,0,780,380);
    else
        graphic.Attach(chart,name);
    graphic.BackgroundMain(StringFormat("Binomial distributionn n=%G p=%G",n_par,p_par));
    graphic.BackgroundMainSize(16);
    //--- plot all curves
    graphic.CurveAdd(x,y,CURVE_HISTOGRAM,"Sample").HistogramWidth(6);
    //--- and now plot the theoretical curve of the distribution density
    graphic.CurveAdd(x2,y2,CURVE_LINES,"Theory").LinesSmooth(true);
    graphic.CurvePlotAll();
    //--- plot all curves
    graphic.Update();
}
//+-----+
//| Calculate frequencies for data set |
//+-----+
bool CalculateHistogramArray(const double &data[],double &intervals[],double &frequency[],
                           double &maxv,double &minv,const int cells=10)
{
    if(cells<=1) return (false);
    int size=ArraySize(data);
    if(size<cells*10) return (false);
    minv=data[ArrayMinimum(data)];
    maxv=data[ArrayMaximum(data)];
    double range=maxv-minv;
    double width=range/cells;
    if(width==0) return false;
    ArrayResize(intervals,cells);
    ArrayResize(frequency,cells);
    //--- define the interval centers
    for(int i=0; i<cells; i++)
    {
        intervals[i]=minv+(i+0.5)*width;
        frequency[i]=0;
    }
    //--- fill the frequencies of falling within the interval
    for(int i=0; i<size; i++)
    {
        int ind=int((data[i]-minv)/width);
        if(ind>=cells) ind=cells-1;
        frequency[ind]++;
    }
    return (true);
}

```

MathProbabilityDensityBinomial

Calculates the value of the probability mass function of binomial distribution with the *n* and *p* parameters for a random variable *x*. In case of error it returns [NaN](#).

```
double MathProbabilityDensityBinomial(
    const double x,           // value of random variable
    const double n,           // parameter of the distribution (number of tests)
    const double p,           // parameter of the distribution (probability of event)
    const bool log_mode,      // calculate the logarithm of the value, if log_mode=true
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability mass function of binomial distribution with the *n* and *p* parameters for a random variable *x*. In case of error it returns [NaN](#).

```
double MathProbabilityDensityBinomial(
    const double x,           // value of random variable
    const double n,           // parameter of the distribution (number of tests)
    const double p,           // parameter of the distribution (probability of event)
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability mass function of binomial distribution with the *n* and *p* parameters for an array of random variables *x[]*. In case of error it returns false. Analog of the [dbinom\(\)](#) in R.

```
bool MathProbabilityDensityBinomial(
    const double& x[],        // array with the values of random variable
    const double n,           // parameter of the distribution (number of tests)
    const double p,           // parameter of the distribution (probability of event)
    const bool log_mode,      // flag to calculate the logarithm of the value, if log_mode=true
    double& result[]          // array for values of the probability density function
);
```

Calculates the value of the probability mass function of binomial distribution with the *n* and *p* parameters for an array of random variables *x[]*. In case of error it returns false.

```
bool MathProbabilityDensityBinomial(
    const double& x[],        // array with the values of random variable
    const double n,           // parameter of the distribution (number of tests)
    const double p,           // parameter of the distribution (probability of event)
    double& result[]          // array for values of the probability density function
);
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

n

[in] Parameter of the distribution (number of tests).

p

[in] Parameter of the distribution (probability of event occurrence in one test).

log_mode

[in] Flag to calculate the logarithm of the value. If `log_mode=true`, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

MathCumulativeDistributionBinomial

Calculates the value of the probability distribution function for binomial law with the n and p parameters for a random variable x . In case of error it returns [NaN](#).

```
double MathCumulativeDistributionBinomial(
    const double x,           // value of random variable
    const double n,           // parameter of the distribution (number of tests)
    const double p,           // parameter of the distribution (probability of event)
    const bool tail,          // flag of calculation, if true, then the probability
    const bool log_mode,      // flag to calculate the logarithm of the value, if 1
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability distribution function for binomial law with the n and p parameters for a random variable x . In case of error it returns [NaN](#).

```
double MathCumulativeDistributionBinomial(
    const double x,           // value of random variable
    const double n,           // parameter of the distribution (number of tests)
    const double p,           // parameter of the distribution (probability of event)
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability distribution function for binomial law with the n and p parameters for an array of random variables $x[]$. In case of error it returns false. Analog of the [pweibull\(\)](#) in R.

```
bool MathCumulativeDistributionBinomial(
    const double& x[],        // array with the values of random variable
    const double n,           // parameter of the distribution (number of tests)
    const double p,           // parameter of the distribution (probability of event)
    const bool tail,          // flag of calculation, if true, then the probability
    const bool log_mode,      // flag to calculate the logarithm of the value, if 1
    double& result[]          // array for values of the probability function
);
```

Calculates the value of the probability distribution function for binomial law with the n and p parameters for an array of random variables $x[]$. In case of error it returns false.

```
bool MathCumulativeDistributionBinomial(
    const double& x[],        // array with the values of random variable
    const double n,           // parameter of the distribution (number of tests)
    const double p,           // parameter of the distribution (probability of event)
    double& result[]          // array for values of the probability function
);
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

n

[in] Parameter of the distribution (number of tests).

p

[in] Parameter of the distribution (probability of event occurrence in one test).

tail

[in] Flag of calculation. If true, then the probability of random variable not exceeding *x* is calculated.

log_mode

[in] Flag to calculate the logarithm of the value. If *log_mode*=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

MathQuantileBinomial

For the specified *probability*, the function calculates the inverse value of distribution function for binomial law with the *n* and *p* parameters. In case of error it returns [NaN](#).

```
double MathQuantileBinomial(
    const double probability, // probability value of random variable occurrence
    const double n,          // parameter of the distribution (number of tests)
    const double p,          // parameter of the distribution (probability of event)
    const bool tail,         // flag of calculation, if false, then calculation is for the head
    const bool log_mode,     // flag of calculation, if log_mode=true, calculation is for the log-likelihood
    int& error_code          // variable to store the error code
);
```

For the specified *probability*, the function calculates the inverse value of distribution function for binomial law with the *n* and *p* parameters. In case of error it returns [NaN](#).

```
double MathQuantileBinomial(
    const double probability, // probability value of random variable occurrence
    const double n,          // parameter of the distribution (number of tests)
    const double p,          // parameter of the distribution (probability of event)
    int& error_code          // variable to store the error code
);
```

For the specified *probability[]* array of probability values, the function calculates the inverse value of distribution function for binomial law with the *n* and *p* parameters. In case of error it returns false. Analog of the [qbinom\(\)](#) in R.

```
double MathQuantileBinomial(
    const double& probability[], // array with probability values of random variable
    const double n,             // parameter of the distribution (number of tests)
    const double p,             // parameter of the distribution (probability of event)
    const bool tail,            // flag of calculation, if false, then calculation is for the head
    const bool log_mode,        // flag of calculation, if log_mode=true, calculation is for the log-likelihood
    double& result[]            // array with values of quantiles
);
```

For the specified *probability[]* array of probability values, the function calculates the inverse value of distribution function for binomial law with the *n* and *p* parameters. In case of error it returns false.

```
bool MathQuantileBinomial(
    const double& probability[], // array with probability values of random variable
    const double n,             // parameter of the distribution (number of tests)
    const double p,             // parameter of the distribution (probability of event)
    double& result[]            // array with values of quantiles
);
```

Parameters

probability

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

n

[in] Parameter of the distribution (number of tests).

p

[in] Parameter of the distribution (probability of event occurrence in one test).

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

MathRandomBinomial

Generates a pseudorandom variable distributed according to the law of binomial distribution with the n and p parameters. In case of error it returns [NaN](#).

```
double MathRandomBinomial (
    const double n,           // parameter of the distribution (number of tests)
    const double p,           // parameter of the distribution (probability of event)
    int& error_code           // variable to store the error code
);
```

Generates pseudorandom variables distributed according to the law of binomial distribution with the n and p parameters. In case of error it returns false. Analog of the [rweibull\(\)](#) in R.

```
bool MathRandomBinomial (
    const double n,           // parameter of the distribution (number of tests)
    const double p,           // parameter of the distribution (probability of event)
    const int data_count,     // amount of required data
    double& result[]          // array with values of pseudorandom variables
);
```

Parameters

n

[in] Parameter of the distribution (number of tests).

p

[in] Parameter of the distribution (probability of event occurrence in one test).

$error_code$

[out] Variable to store the error code.

$data_count$

[out] Amount of required data.

$result[]$

[out] Array to obtain the values of pseudorandom variables.

MathMomentsBinomial

Calculates the theoretical numerical values of the first 4 moments of the binomial distribution with the *n* and *p* parameters.

```
double MathMomentsBinomial(  
    const double n,           // parameter of the distribution (number of tests)  
    const double p,           // parameter of the distribution (probability of event occurrence)  
    double& mean,             // variable for the mean  
    double& variance,         // variable for the variance  
    double& skewness,         // variable for the skewness  
    double& kurtosis,         // variable for the kurtosis  
    int& error_code           // variable for the error code  
);
```

Parameters

n

[in] Parameter of the distribution (number of tests).

p

[in] Parameter of the distribution (probability of event occurrence in one test).

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

Negative binomial distribution

This section contains functions for working with negative binomial distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the negative binomial law. The negative binomial distribution is defined by the following formula:

$$f_{\text{NegativeBinomial}}(x|r,p) = \frac{\Gamma(r+x)}{\Gamma(r)\Gamma(x+1)} p^r (1-p)^x$$

where:

- x – value of the random variable
- r – number of successful tests
- p – probability of success

In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityNegativeBinomial	Calculates the probability density function of the negative binomial distribution
MathCumulativeDistributionNegativeBinomial	Calculates the value of the negative binomial probability distribution function
MathQuantileNegativeBinomial	Calculates the value of the inverse negative binomial distribution function for the specified probability
MathRandomNegativeBinomial	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the negative binomial law

MathMomentsNegativeBinomial

Calculates the theoretical numerical values of the first 4 moments of the negative binomial distribution

Example:

```
#include <Graphics\Graphic.mqh>
#include <Math\Stat\NegativeBinomial.mqh>
#include <Math\Stat\Math.mqh>
#property script_show_inputs
//--- input parameters
input double n_par=40;           // the number of tests
input double p_par=0.75;         // probability of success for each test
//+-----+
//| Script program start function |
//+-----+
void OnStart()
{
//--- hide the price chart
    ChartSetInteger(0,CHART_SHOW,false);
//--- initialize the random number generator
    MathSrand(GetTickCount());
//--- generate a sample of the random variable
    long chart=0;
    string name="GraphicNormal";
    int n=1000000;           // the number of values in the sample
    int ncells=19;           // the number of intervals in the histogram
    double x[];              // centers of the histogram intervals
    double y[];              // the number of values from the sample falling within the int
    double data[];           // sample of random values
    double max,min;          // the maximum and minimum values in the sample
//--- obtain a sample from the negative binomial distribution
    MathRandomNegativeBinomial(n_par,p_par,n,data);
//--- calculate the data to plot the histogram
    CalculateHistogramArray(data,x,y,max,min,ncells);
//--- obtain the theoretically calculated data at the interval of [min,max]
    double x2[];
    double y2[];
    MathSequence(0,n_par,1,x2);
    MathProbabilityDensityNegativeBinomial(x2,n_par,p_par,false,y2);
//--- set the scale
    double theor_max=y2[ArrayMaximum(y2)];
    double sample_max=y[ArrayMaximum(y)];
    double k=sample_max/theor_max;
    for(int i=0; i<ncells; i++)
        y[i]/=k;
//--- output charts
    CGraphic graphic;
```

```

    if (ObjectFind(chart,name)<0)
        graphic.Create(chart,name,0,0,0,780,380);
    else
        graphic.Attach(chart,name);
    graphic.BackgroundMain(StringFormat("Negative Binomial distributionn n=%G p=%G",n,p));
    graphic.BackgroundMainSize(16);
//--- plot all curves
    graphic.CurveAdd(x,y,CURVE_HISTOGRAM,"Sample").HistogramWidth(6);
//--- and now plot the theoretical curve of the distribution density
    graphic.CurveAdd(x2,y2,CURVE_LINES,"Theory").LinesSmooth(true);
    graphic.CurvePlotAll();
//--- plot all curves
    graphic.Update();
}
//+-----+
//| Calculate frequencies for data set |
//+-----+
bool CalculateHistogramArray(const double &data[],double &intervals[],double &frequency[],
                           double &maxv,double &minv,const int cells=10)
{
    if(cells<=1) return (false);
    int size=ArraySize(data);
    if(size<cells*10) return (false);
    minv=data[ArrayMinimum(data)];
    maxv=data[ArrayMaximum(data)];
    double range=maxv-minv;
    double width=range/cells;
    if(width==0) return false;
    ArrayResize(intervals,cells);
    ArrayResize(frequency,cells);
//--- define the interval centers
    for(int i=0; i<cells; i++)
    {
        intervals[i]=minv+(i+0.5)*width;
        frequency[i]=0;
    }
//--- fill the frequencies of falling within the interval
    for(int i=0; i<size; i++)
    {
        int ind=int((data[i]-minv)/width);
        if(ind>=cells) ind=cells-1;
        frequency[ind]++;
    }
    return (true);
}

```

MathProbabilityDensityNegativeBinomial

Calculates the value of the probability mass function of negative binomial distribution with the *r* and *p* parameters for a random variable *x*. In case of error it returns [NaN](#).

```
double MathProbabilityDensityNegativeBinomial(
    const double x,           // value of random variable (integer)
    const double r,           // number of successful tests
    const double p,           // probability of success
    const bool log_mode,      // calculate the logarithm of the value, if log_mode=true
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability mass function of negative binomial distribution with the *r* and *p* parameters for a random variable *x*. In case of error it returns [NaN](#).

```
double MathProbabilityDensityNegativeBinomial(
    const double x,           // value of random variable (integer)
    const double r,           // number of successful tests
    const double p,           // probability of success
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability mass function of negative binomial distribution with the *r* and *p* parameters for an array of random variables *x[]*. In case of error it returns false. Analog of the [dnbinom\(\)](#) in R.

```
bool MathProbabilityDensityNegativeBinomial(
    const double& x[],        // array with the values of random variable
    const double r,           // number of successful tests
    const double p,           // probability of success
    const bool log_mode,      // flag to calculate the logarithm of the value, if log_mode=true
    double& result[]         // array for values of the probability density function
);
```

Calculates the value of the probability mass function of negative binomial distribution with the *r* and *p* parameters for an array of random variables *x[]*. In case of error it returns false.

```
bool MathProbabilityDensityNegativeBinomial(
    const double& x[],        // array with the values of random variable
    const double r,           // number of successful tests
    const double p,           // probability of success
    double& result[]         // array for values of the probability density function
);
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

r

[in] Number of successful tests

p

[in] Probability of success.

log_mode

[in] Flag to calculate the logarithm of the value. If `log_mode=true`, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

MathCumulativeDistributionNegativeBinomial

Calculates the value of the probability distribution function for negative binomial law with the *r* and *p* parameters for a random variable *x*. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionNegativeBinomial(
    const double x,           // value of random variable (integer)
    const double r,           // number of successful tests
    const double p,           // probability of success
    const bool tail,          // flag of calculation, if true, then the probability
    const bool log_mode,      // flag to calculate the logarithm of the value, if 1
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability distribution function for negative binomial law with the *r* and *p* parameters for a random variable *x*. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionNegativeBinomial(
    const double x,           // value of random variable (integer)
    const double r,           // number of successful tests
    const double p,           // probability of success
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability distribution function for negative binomial law with the *r* and *p* parameters for an array of random variables *x[]*. In case of error it returns false. Analog of the [pweibull\(\)](#) in R.

```
bool MathCumulativeDistributionNegativeBinomial(
    const double& x[],        // array with the values of random variable
    const double r,           // number of successful tests
    const double p,           // probability of success
    const bool tail,          // flag of calculation, if true, then the probability
    const bool log_mode,      // flag to calculate the logarithm of the value, if 1
    double& result[]         // array for values of the probability function
);
```

Calculates the value of the probability distribution function for negative binomial law with the *r* and *p* parameters for an array of random variables *x[]*. In case of error it returns false.

```
bool MathCumulativeDistributionNegativeBinomial(
    const double& x[],        // array with the values of random variable
    const double r,           // number of successful tests
    const double p,           // probability of success
    double& result[]         // array for values of the probability function
);
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

r

[in] Number of successful tests.

p

[in] Probability of success.

tail

[in] Flag of calculation, if true, then the probability of random variable not exceeding *x* is calculated.

log_mode

[in] Flag to calculate the logarithm of the value, if *log_mode*=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

MathQuantileNegativeBinomial

For the specified *probability*, the function calculates the inverse value of distribution function for negative binomial law with the *r* and *p* parameters. In case of error it returns [NaN](#).

```
double MathQuantileNegativeBinomial(
    const double probability, // probability value of random variable occurrence
    const double r,          // number of successful tests
    const double p,          // probability of success
    const bool tail,         // flag of calculation, if false, then calculation is
    const bool log_mode,     // flag of calculation, if log_mode=true, calculation
    int& error_code          // variable to store the error code
);
```

For the specified *probability*, the function calculates the inverse value of distribution function for negative binomial law with the *r* and *p* parameters. In case of error it returns [NaN](#).

```
double MathQuantileNegativeBinomial(
    const double probability, // probability value of random variable occurrence
    const double r,          // number of successful tests
    const double p,          // probability of success
    int& error_code          // variable to store the error code
);
```

For the specified *probability[]* array of probability values, the function calculates the inverse value of distribution function for negative binomial law with the *r* and *p* parameters. In case of error it returns false. Analog of the [qnbinom\(\)](#) in R.

```
double MathQuantileNegativeBinomial(
    const double& probability[], // array with probability values of random variable
    const double r,             // number of successful tests
    const double p,             // probability of success
    const bool tail,            // flag of calculation, if false, then calculation is
    const bool log_mode,        // flag of calculation, if log_mode=true, calculation
    double& result[]            // array with values of quantiles
);
```

For the specified *probability[]* array of probability values, the function calculates the inverse value of distribution function for negative binomial law with the *r* and *p* parameters. In case of error it returns false.

```
bool MathQuantileNegativeBinomial(
    const double& probability[], // array with probability values of random variable
    const double r,             // number of successful tests
    const double p,             // probability of success
    double& result[]            // array with values of quantiles
);
```

Parameters

probability

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

r

[in] Number of successful tests.

p

[in] Probability of success.

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

MathRandomNegativeBinomial

Generates a pseudorandom variable distributed according to the law of negative binomial distribution with the *r* and *p* parameters. In case of error it returns [NaN](#).

```
double MathRandomNegativeBinomial(  
    const double r,           // number of successful tests  
    const double p,           // probability of success  
    int& error_code           // variable to store the error code  
);
```

Generates pseudorandom variables distributed according to the law of negative binomial distribution with the *r* and *p* parameters. In case of error it returns false. Analog of the [rweibull\(\)](#) in R.

```
bool MathRandomNegativeBinomial(  
    const double r,           // number of successful tests  
    const double p,           // probability of success  
    const int data_count,     // amount of required data  
    double& result[]          // array with values of pseudorandom variables  
);
```

Parameters

r

[in] Number of successful tests.

p

[in] Probability of success.

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

MathMomentsNegativeBinomial

Calculates the theoretical numerical values of the first 4 moments of the negative binomial distribution with the *r* and *p* parameters.

```
double MathMomentsNegativeBinomial(  
    const double r,           // number of successful tests  
    const double p,           // probability of success  
    double& mean,             // variable for the mean  
    double& variance,         // variable for the variance  
    double& skewness,         // variable for the skewness  
    double& kurtosis,         // variable for the kurtosis  
    int& error_code          // variable for the error code  
);
```

Parameters

r

[in] Number of successful tests.

p

[in] Probability of success.

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

Geometric distribution

This section contains functions for working with geometric distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the geometric law. The geometric distribution is defined by the following formula:

$$f_{\text{Geometric}}(x|p) = p(1-p)^x$$

where:

- x – value of the random variable (integer)
- p – probability of event occurrence in one test

In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
<u>MathProbabilityDensityGeometric</u>	Calculates the probability density function of the geometric distribution
<u>MathCumulativeDistributionGeometric</u>	Calculates the value of the geometric probability distribution function
<u>MathQuantileGeometric</u>	Calculates the value of the inverse geometric distribution function for the specified probability
<u>MathRandomGeometric</u>	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the geometric law
<u>MathMomentsGeometric</u>	Calculates the theoretical numerical values of the first 4 moments of the geometric distribution

Example:

```

#include <Graphics\Graphic.mqh>
#include <Math\Stat\Geometric.mqh>
#include <Math\Stat\Math.mqh>
#property script_show_inputs
//--- input parameters
input double p_par=0.2;      // probability of event occurrence in one test
//+-----+
//| Script program start function |
//+-----+
void OnStart()
{
//--- hide the price chart
    ChartSetInteger(0, CHART_SHOW, false);
//--- initialize the random number generator
    MathSrand(GetTickCount());
//--- generate a sample of the random variable
    long chart=0;
    string name="GraphicNormal";
    int n=1000000;      // the number of values in the sample
    int ncells=47;      // the number of intervals in the histogram
    double x[];         // centers of the histogram intervals
    double y[];         // the number of values from the sample falling within the int
    double data[];      // sample of random values
    double max,min;     // the maximum and minimum values in the sample
//--- obtain a sample from the geometric distribution
    MathRandomGeometric(p_par,n,data);
//--- calculate the data to plot the histogram
    CalculateHistogramArray(data,x,y,max,min,ncells);
//--- obtain the sequence boundaries and the step for plotting the theoretical curve
    double step;
    GetMaxMinStepValues(max,min,step);
    PrintFormat("max=%G min=%G",max,min);
//--- obtain the theoretically calculated data at the interval of [min,max]
    double x2[];
    double y2[];
    MathSequence(0,ncells,1,x2);
    MathProbabilityDensityGeometric(x2,p_par,false,y2);
//--- set the scale
    double theor_max=y2[ArrayMaximum(y2)];
    double sample_max=y[ArrayMaximum(y)];
    double k=sample_max/theor_max;
    for(int i=0; i<ncells; i++)
        y[i]/=k;
//--- output charts
    CGraphic graphic;
    if(ObjectFind(chart,name)<0)
        graphic.Create(chart,name,0,0,0,780,380);

```

```

else
    graphic.Attach(chart,name);

    minv=NormalizeDouble(minv,degree);
    //-- sequence generation step is also set based on the specified precision
    stepv=NormalizeDouble(MathPow(10,-degree),degree);
    if((maxv-minv)/stepv<10)
        stepv/=10.;
}
```

MathProbabilityDensityGeometric

Calculates the value of the probability mass function of geometric distribution with the p parameter for a random variable x . In case of error it returns [NaN](#).

```
double MathProbabilityDensityGeometric(
    const double x,           // value of random variable (integer)
    const double p,           // parameter of the distribution (probability of event)
    const bool log_mode,      // calculate the logarithm of the value, if log_mode=true
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability mass function of geometric distribution with the p parameter for a random variable x . In case of error it returns [NaN](#).

```
double MathProbabilityDensityGeometric(
    const double x,           // value of random variable (integer)
    const double p,           // parameter of the distribution (probability of event)
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability mass function of geometric distribution with the p parameter for an array of random variables $x[]$. In case of error it returns false. Analog of the [dgeom\(\)](#) in R.

```
bool MathProbabilityDensityGeometric(
    const double& x[],        // array with the values of random variable
    const double p,           // parameter of the distribution (probability of event)
    const bool log_mode,      // flag to calculate the logarithm of the value, if log_mode=true
    double& result[]          // array for values of the probability density function
);
```

Calculates the value of the probability mass function of geometric distribution with the p parameter for an array of random variables $x[]$. In case of error it returns false.

```
bool MathProbabilityDensityGeometric(
    const double& x[],        // array with the values of random variable
    const double p,           // parameter of the distribution (probability of event)
    double& result[]          // array for values of the probability density function
);
```

Parameters

x

[in] Value of random variable.

$x[]$

[in] Array with the values of random variable.

p

[in] Parameter of the distribution (probability of event occurrence in one test).

\log_mode

[in] Flag to calculate the logarithm of the value. If `log_mode=true`, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

MathCumulativeDistributionGeometric

Calculates the value of the probability distribution function for geometric law with the *p* parameter for a random variable *x*. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionGeometric(
    const double x,           // value of random variable (integer)
    const double p,           // parameter of the distribution (probability of event)
    const bool tail,          // flag of calculation, if true, then the probability
    const bool log_mode,      // flag to calculate the logarithm of the value, if 1
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability distribution function for geometric law with the *p* parameter for a random variable *x*. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionGeometric(
    const double x,           // value of random variable (integer)
    const double p,           // parameter of the distribution (probability of event)
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability distribution function for geometric law with the *p* parameter for an array of random variables *x[]*. In case of error it returns false. Analog of the [pgeom\(\)](#) in R.

```
bool MathCumulativeDistributionGeometric(
    const double& x[],        // array with the values of random variable
    const double p,           // parameter of the distribution (probability of event)
    const bool tail,          // flag of calculation, if true, then the probability
    const bool log_mode,      // flag to calculate the logarithm of the value, if 1
    double& result[]          // array for values of the probability function
);
```

Calculates the value of the probability distribution function for geometric law with the *p* parameter for an array of random variables *x[]*. In case of error it returns false.

```
bool MathCumulativeDistributionGeometric(
    const double& x[],        // array with the values of random variable
    const double p,           // parameter of the distribution (probability of event)
    double& result[]          // array for values of the probability function
);
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

p

[in] Parameter of the distribution (probability of event occurrence in one test).

tail

[in] Flag of calculation, if tail=true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value, if log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability function.

MathQuantileGeometric

For the specified *probability*, the function calculates the inverse value of distribution function for geometric law with the *p* parameter. In case of error it returns [NaN](#).

```
double MathQuantileGeometric(
    const double probability, // probability value of random variable occurrence
    const double p,          // parameter of the distribution (probability of event)
    const bool tail,         // flag of calculation, if false, then calculation is for left tail
    const bool log_mode,     // flag of calculation, if log_mode=true, calculation is for log scale
    int& error_code          // variable to store the error code
);
```

For the specified *probability*, the function calculates the inverse value of distribution function for geometric law with the *p* parameter. In case of error it returns [NaN](#).

```
double MathQuantileGeometric(
    const double probability, // probability value of random variable occurrence
    const double p,          // parameter of the distribution (probability of event)
    int& error_code          // variable to store the error code
);
```

For the specified *probability[]* array of probability values, the function calculates the inverse value of distribution function for geometric law with the *p* parameter. In case of error it returns false. Analog of the [qgeom\(\)](#) in R.

```
double MathQuantileGeometric(
    const double& probability[], // array with probability values of random variable
    const double p,             // parameter of the distribution (probability of event)
    const bool tail,            // flag of calculation, if false, then calculation is for left tail
    const bool log_mode,        // flag of calculation, if log_mode=true, calculation is for log scale
    double& result[]            // array with values of quantiles
);
```

For the specified *probability[]* array of probability values, the function calculates the inverse value of distribution function for geometric law with the *p* parameter. In case of error it returns false.

```
bool MathQuantileGeometric(
    const double& probability[], // array with probability values of random variable
    const double p,             // parameter of the distribution (probability of event)
    double& result[]            // array with values of quantiles
);
```

Parameters

probability

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

p

[in] Parameter of the distribution (probability of event occurrence in one test).

tail

[in] Flag of calculation, if false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

MathRandomGeometric

Generates a pseudorandom variable distributed according to the law of geometric distribution with the p parameter. In case of error it returns [NaN](#).

```
double MathRandomGeometric(  
    const double p,           // parameter of the distribution (probability of event occurrence)  
    int& error_code           // variable to store the error code  
);
```

Generates pseudorandom variables distributed according to the law of geometric distribution with the p parameter. In case of error it returns false. Analog of the [rgeom\(\)](#) in R.

```
bool MathRandomGeometric(  
    const double p,           // parameter of the distribution (probability of event occurrence)  
    const int data_count,     // amount of required data  
    double& result[]          // array with values of pseudorandom variables  
);
```

Parameters

p

[in] Parameter of the distribution (probability of event occurrence in one test).

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

MathMomentsGeometric

Calculates the theoretical numerical values of the first 4 moments of the geometric distribution with the p parameter.

```
double MathMomentsGeometric(  
    const double p,           // parameter of the distribution (probability of event occurrence in one test)  
    double& mean,             // variable for the mean  
    double& variance,         // variable for the variance  
    double& skewness,         // variable for the skewness  
    double& kurtosis,         // variable for the kurtosis  
    int& error_code           // variable for the error code  
);
```

Parameters

p

[in] Parameter of the distribution (probability of event occurrence in one test).

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

Hypergeometric distribution

This section contains functions for working with hypergeometric distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the hypergeometric law. The hypergeometric distribution is defined by the following formula:

$$f_{Hypergeometric}(x | m, k, n) = \frac{\binom{k}{x} \binom{m-k}{n-x}}{\binom{m}{n}}$$

where:

- x — value of the random variable (integer)
- m — total number of objects
- k — number of objects with the desired characteristic
- n — number of object draws

In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityHypergeometric	Calculates the probability density function of the hypergeometric distribution
MathCumulativeDistributionHypergeometric	Calculates the value of the hypergeometric probability distribution function
MathQuantileHypergeometric	Calculates the value of the inverse hypergeometric distribution function for the specified probability

<u>MathRandomHypergeometric</u>	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the hypergeometric law
<u>MathMomentsHypergeometric</u>	Calculates the theoretical numerical values of the first 4 moments of the hypergeometric distribution

Example:

```

#include <Graphics\Graphic.mqh>
#include <Math\Stat\Hypergeometric.mqh>
#include <Math\Stat\Math.mqh>
#property script_show_inputs
//--- input parameters
input double m_par=60;      // the total number of objects
input double k_par=30;      // the number of objects with the desired characteristic
input double n_par=30;      // the number of object draws
//+-----+
//| Script program start function |
//+-----+
void OnStart()
{
//--- hide the price chart

}

```

MathProbabilityDensityHypergeometric

Calculates the value of the probability mass function of hypergeometric distribution with the m , k and n parameters for a random variable x . In case of error it returns [NaN](#).

```
double MathProbabilityDensityHypergeometric(
    const double x,           // value of random variable (integer)
    const double m,           // total number of objects (integer)
    const double k,           // number of objects with the desired characteristic
    const double n,           // number of object draws (integer)
    const bool log_mode,      // calculate the logarithm of the value, if log_mode=true
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability mass function of hypergeometric distribution with the m , k and n parameters for a random variable x . In case of error it returns [NaN](#).

```
double MathProbabilityDensityHypergeometric(
    const double x,           // value of random variable (integer)
    const double m,           // total number of objects (integer)
    const double k,           // number of objects with the desired characteristic
    const double n,           // number of object draws (integer)
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability mass function of hypergeometric distribution with the m , k and n parameters for an array of random variables $x[]$. In case of error it returns false. Analog of the [dhyper\(\)](#) in R.

```
bool MathProbabilityDensityHypergeometric(
    const double& x[],        // array with the values of random variable
    const double m,           // total number of objects (integer)
    const double k,           // number of objects with the desired characteristic
    const double n,           // number of object draws (integer)
    const bool log_mode,      // flag to calculate the logarithm of the value, if log_mode=true
    double& result[]         // array for values of the probability density function
);
```

Calculates the value of the probability mass function of hypergeometric distribution with the m , k and n parameters for an array of random variables $x[]$. In case of error it returns false.

```
bool MathProbabilityDensityHypergeometric(
    const double& x[],        // array with the values of random variable
    const double m,           // total number of objects (integer)
    const double k,           // number of objects with the desired characteristic
    const double n,           // number of object draws (integer)
    double& result[]         // array for values of the probability density function
);
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

m

[in] Total number of objects (integer).

k

[in] Number of objects with the desired characteristic (integer).

n

[in] Number of object draws (integer).

log_mode

[in] Flag to calculate the logarithm of the value. If log_mode=true, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

MathCumulativeDistributionHypergeometric

Calculates the value of the probability distribution function for hypergeometric law with the m , k and n parameters for a random variable x . In case of error it returns [NaN](#).

```
double MathCumulativeDistributionHypergeometric(
    const double x,           // value of random variable (integer)
    const double m,           // total number of objects (integer)
    const double k,           // number of objects with the desired characteristic
    const double n,           // number of object draws (integer)
    const bool tail,          // flag of calculation, if true, then the probability
    const bool log_mode,      // flag to calculate the logarithm of the value, if 1
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability distribution function for hypergeometric law with the m , k and n parameters for a random variable x . In case of error it returns [NaN](#).

```
double MathCumulativeDistributionHypergeometric(
    const double x,           // value of random variable (integer)
    const double m,           // total number of objects (integer)
    const double k,           // number of objects with the desired characteristic
    const double n,           // number of object draws (integer)
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability distribution function for hypergeometric law with the m , k and n parameters for an array of random variables $x[]$. In case of error it returns false. Analog of the [dhyper\(\)](#) in R.

```
bool MathCumulativeDistributionHypergeometric(
    const double& x[],        // array with the values of random variable
    const double m,           // total number of objects (integer)
    const double k,           // number of objects with the desired characteristic
    const double n,           // number of object draws (integer)
    const bool tail,          // flag of calculation, if true, then the probability
    const bool log_mode,      // flag to calculate the logarithm of the value, if 1
    double& result[]         // array for values of the distribution function
);
```

Calculates the value of the probability distribution function for hypergeometric law with the m , k and n parameters for an array of random variables $x[]$. In case of error it returns false.

```
bool MathCumulativeDistributionHypergeometric(
    const double& x[],        // array with the values of random variable
    const double m,           // total number of objects (integer)
    const double k,           // number of objects with the desired characteristic
    const double n,           // number of object draws (integer)
    double& result[]         // array for values of the distribution function
);
```

Parameters*x*

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

m

[in] Total number of objects (integer).

k

[in] Number of objects with the desired characteristic (integer).

n

[in] Number of object draws (integer).

tail

[in] Flag of calculation, if true, then the probability of random variable not exceeding *x* is calculated.

log_mode

[in] Flag to calculate the logarithm of the value, if *log_mode*=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the distribution function.

MathQuantileHypergeometric

For the specified *probability*, the function calculates the inverse value of distribution function for hypergeometric law with the *m*, *k* and *n* parameters. In case of error it returns [NaN](#).

```
double MathQuantileHypergeometric(
    const double probability, // probability value of random variable occurrence
    const double m,          // total number of objects (integer)
    const double k,          // number of objects with the desired characteristic
    const double n,          // number of object draws (integer)
    const bool tail,         // flag of calculation, if false, then calculation is
    const bool log_mode,     // flag of calculation, if log_mode=true, calculation
    int& error_code          // variable to store the error code
);
```

For the specified *probability*, the function calculates the inverse value of distribution function for hypergeometric law with the *m*, *k* and *n* parameters. In case of error it returns [NaN](#).

```
double MathQuantileHypergeometric(
    const double probability, // probability value of random variable occurrence
    const double m,          // total number of objects (integer)
    const double k,          // number of objects with the desired characteristic
    const double n,          // number of object draws (integer)
    int& error_code          // variable to store the error code
);
```

For the specified *probability[]* array of probability values, the function calculates the inverse value of distribution function for hypergeometric law with the *m*, *k* and *n* parameters. In case of error it returns false. Analog of the [ghyper\(\)](#) in R.

```
double MathQuantileHypergeometric(
    const double& probability[], // array with probability values of random variable
    const double m,             // total number of objects (integer)
    const double k,             // number of objects with the desired characteristic
    const double n,             // number of object draws (integer)
    const bool tail,            // flag of calculation, if false, then calculation is
    const bool log_mode,        // flag of calculation, if log_mode=true, calculation
    double& result[]            // array with values of quantiles
);
```

For the specified *probability[]* array of probability values, the function calculates the inverse value of distribution function for hypergeometric law with the *m*, *k* and *n* parameters. In case of error it returns false.

```
bool MathQuantileHypergeometric(
    const double& probability[], // array with probability values of random variable
    const double m,             // total number of objects (integer)
    const double k,             // number of objects with the desired characteristic
    const double n,             // number of object draws (integer)
    double& result[]            // array with values of quantiles
);
```

```
);
```

Parameters*probability*

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

m

[in] Total number of objects (integer).

k

[in] Number of objects with the desired characteristic (integer).

n

[in] Number of object draws (integer).

tail

[in] Flag of calculation, if tail=false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

MathRandomHypergeometric

Generates a pseudorandom variable distributed according to the law of hypergeometric distribution with the *m*, *n* and *k* parameters. In case of error it returns [NaN](#).

```
double MathRandomHypergeometric(  
    const double m,           // total number of objects (integer)  
    const double k,           // number of objects with the desired characteristic  
    const double n,           // number of object draws (integer)  
    int& error_code           // variable to store the error code  
);
```

Generates pseudorandom variables distributed according to the law of hypergeometric distribution with the *m*, *n* and *k* parameters. In case of error it returns false. Analog of the [rgeom\(\)](#) in R.

```
bool MathRandomHypergeometric(  
    const double m,           // total number of objects (integer)  
    const double k,           // number of objects with the desired characteristic  
    const double n,           // number of object draws (integer)  
    const int data_count,     // amount of required data  
    double& result[]          // array with values of pseudorandom variables  
);
```

Parameters

m

[in] Total number of objects (integer).

k

[in] Number of objects with the desired characteristic (integer).

n

[in] Number of object draws (integer).

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

MathMomentsHypergeometric

Calculates the theoretical numerical values of the first 4 moments of the hypergeometric distribution with the m, n and k parameters.

```
double MathMomentsHypergeometric(  
    const double m,           // total number of objects (integer)  
    const double k,           // number of objects with the desired characteristic  
    const double n,           // number of object draws (integer)  
    double& mean,             // variable for the mean  
    double& variance,         // variable for the variance  
    double& skewness,         // variable for the skewness  
    double& kurtosis,         // variable for the kurtosis  
    int& error_code           // variable for the error code  
);
```

Parameters

m

[in] Total number of objects (integer).

k

[in] Number of objects with the desired characteristic (integer).

n

[in] Number of object draws (integer).

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

Poisson distribution

This section contains functions for working with Poisson distribution. They allow to calculate density, probability, quantiles and to generate pseudo-random numbers distributed according to the Poisson law. The Poisson distribution is defined by the following formula:

$$f_{Poisson}(x|\lambda) = \frac{\lambda^x}{x!} e^{-\lambda}$$

where:

- x – value of the random variable
- λ – parameter of the distribution (mean)

In addition to the calculation of the individual random variables, the library also implements the ability to work with arrays of random variables.

Function	Description
MathProbabilityDensityPoisson	Calculates the probability density function of the Poisson distribution
MathCumulativeDistributionPoisson	Calculates the value of the Poisson probability distribution function
MathQuantilePoisson	Calculates the value of the inverse Poisson distribution function for the specified probability
MathRandomPoisson	Generates a pseudorandom variable/array of pseudorandom variables distributed according to the Poisson law
MathMomentsPoisson	Calculates the theoretical numerical values of the first 4 moments of the Poisson distribution

Example:

```

#include <Graphics\Graphic.mqh>
#include <Math\Stat\Poisson.mqh>
#include <Math\Stat\Math.mqh>
#property script_show_inputs
//--- input parameters
input double lambda_par=10;      // parameter of the distribution (mean)
//+-----+
//| Script program start function |
//+-----+
void OnStart()

    if((maxv-minv)/stepv<10)
        stepv/=10.;
}
```

MathProbabilityDensityPoisson

Calculates the value of the probability mass function of Poisson distribution with the lambda parameter for a random variable x. In case of error it returns [NaN](#).

```
double MathProbabilityDensityPoisson(
    const double x,           // value of random variable (integer)
    const double lambda,      // parameter of the distribution (mean)
    const bool log_mode,      // calculate the logarithm of the value, if log_mode=true
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability mass function of Poisson distribution with the lambda parameter for a random variable x. In case of error it returns [NaN](#).

```
double MathProbabilityDensityPoisson(
    const double x,           // value of random variable (integer)
    const double lambda,      // parameter of the distribution (mean)
    int& error_code           // variable to store the error code
);
```

Calculates the value of the probability mass function of Poisson distribution with the lambda parameter for an array of random variables x[]. In case of error it returns false. Analog of the [dhyper\(\)](#) in R.

```
bool MathProbabilityDensityPoisson(
    const double& x[],        // array with the values of random variable
    const double lambda,      // parameter of the distribution (mean)
    const bool log_mode,      // flag to calculate the logarithm of the value, if log_mode=true
    double& result[]         // array for values of the probability density function
);
```

Calculates the value of the probability mass function of Poisson distribution with the lambda parameter for an array of random variables x[]. In case of error it returns false.

```
bool MathProbabilityDensityPoisson(
    const double& x[],        // array with the values of random variable
    const double lambda,      // parameter of the distribution (mean)
    double& result[]         // array for values of the probability density function
);
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

lambda

[in] Parameter of the distribution (mean).

log_mode

[in] Flag to calculate the logarithm of the value. If `log_mode=true`, then the natural logarithm of the probability density is returned.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the probability density function.

MathCumulativeDistributionPoisson

Calculates the value of the Poisson distribution function with the lambda parameter for a random variable x. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionPoisson(
    const double x,           // value of random variable (integer)
    const double lambda,      // parameter of the distribution (mean)
    const bool tail,          // flag of calculation, if true, then the probability
    const bool log_mode,      // flag to calculate the logarithm of the value, if 1
    int& error_code           // variable to store the error code
);
```

Calculates the value of the Poisson distribution function with the lambda parameter for a random variable x. In case of error it returns [NaN](#).

```
double MathCumulativeDistributionPoisson(
    const double x,           // value of random variable (integer)
    const double lambda,      // parameter of the distribution (mean)
    int& error_code           // variable to store the error code
);
```

Calculates the value of the Poisson distribution function with the lambda parameter for an array of random variables x[]. In case of error it returns false. Analog of the [dhyper\(\)](#) in R.

```
bool MathCumulativeDistributionPoisson(
    const double& x[],        // array with the values of random variable
    const double lambda,      // parameter of the distribution (mean)
    const bool tail,          // flag of calculation, if true, then the probability
    const bool log_mode,      // flag to calculate the logarithm of the value, if 1
    double& result[]          // array for values of the distribution function
);
```

Calculates the value of the Poisson distribution function with the lambda parameter for an array of random variables x[]. In case of error it returns false.

```
bool MathCumulativeDistributionPoisson(
    const double& x[],        // array with the values of random variable
    const double lambda,      // parameter of the distribution (mean)
    double& result[]          // array for values of the distribution function
);
```

Parameters

x

[in] Value of random variable.

x[]

[in] Array with the values of random variable.

lambda

[in] Parameter of the distribution (mean).

tail

[in] Flag of calculation, if true, then the probability of random variable not exceeding x is calculated.

log_mode

[in] Flag to calculate the logarithm of the value, if log_mode=true, then the natural logarithm of the probability is calculated.

error_code

[out] Variable to store the error code.

result[]

[out] Array for values of the distribution function.

MathQuantilePoisson

For the specified *probability*, the function calculates the inverse value of Poisson distribution function with the lambda parameter. In case of error it returns [NaN](#).

```
double MathQuantilePoisson(
    const double probability, // probability value of random variable occurrence
    const double lambda,     // parameter of the distribution (mean)
    const bool tail,         // flag of calculation, if false, then calculation is
    const bool log_mode,     // flag of calculation, if log_mode=true, calculation
    int& error_code          // variable to store the error code
);
```

For the specified *probability*, the function calculates the inverse value of Poisson distribution function with the lambda parameter. In case of error it returns [NaN](#).

```
double MathQuantilePoisson(
    const double probability, // probability value of random variable occurrence
    const double lambda,     // parameter of the distribution (mean)
    int& error_code          // variable to store the error code
);
```

For the specified *probability[]* array of probability values, the function calculates the inverse value of Poisson distribution function with the lambda parameter. In case of error it returns false. Analog of the [ghyper\(\)](#) in R.

```
double MathQuantilePoisson(
    const double& probability[], // array with probability values of random variable
    const double lambda,        // parameter of the distribution (mean)
    const bool tail,            // flag of calculation, if false, then calculation is
    const bool log_mode,        // flag of calculation, if log_mode=true, calculation
    double& result[]            // array with values of quantiles
);
```

For the specified *probability[]* array of probability values, the function calculates the inverse value of Poisson distribution function with the lambda parameter. In case of error it returns false.

```
bool MathQuantilePoisson(
    const double& probability[], // array with probability values of random variable
    const double lambda,        // parameter of the distribution (mean)
    double& result[]            // array with values of quantiles
);
```

Parameters

probability

[in] Probability value of random variable.

probability[]

[in] Array with probability values of random variable.

lambda

[in] Parameter of the distribution (mean).

tail

[in] Flag of calculation, if tail=false, then calculation is performed for 1.0-probability.

log_mode

[in] Flag of calculation, if log_mode=true, calculation is performed for Exp(probability).

error_code

[out] Variable to get the error code.

result[]

[out] Array with values of quantiles.

MathRandomPoisson

Generates a pseudorandom variable distributed according to the law of Poisson distribution with the lambda parameter. In case of error it returns [NaN](#).

```
double MathRandomPoisson(  
    const double lambda,          // parameter of the distribution (mean)  
    int& error_code               // variable to store the error code  
);
```

Generates pseudorandom variables distributed according to the law of Poisson distribution with the lambda parameter. In case of error it returns false. Analog of the [rgeom\(\)](#) in R.

```
bool MathRandomPoisson(  
    const double lambda,          // parameter of the distribution (mean)  
    const int data_count,         // amount of required data  
    double& result[]             // array with values of pseudorandom variables  
);
```

Parameters

lambda

[in] Parameter of the distribution (mean).

error_code

[out] Variable to store the error code.

data_count

[out] Amount of required data.

result[]

[out] Array to obtain the values of pseudorandom variables.

MathMomentsPoisson

Calculates the theoretical numerical values of the first 4 moments of the Poisson distribution with the lambda parameter.

```
double MathMomentsPoisson(  
    const double lambda,      // parameter of the distribution (mean)  
    double& mean,             // variable for the mean  
    double& variance,         // variable for the variance  
    double& skewness,         // variable for the skewness  
    double& kurtosis,         // variable for the kurtosis  
    int& error_code           // variable for the error code  
);
```

Parameters

lambda

[in] Parameter of the distribution (mean).

mean

[out] Variable to get the mean value.

variance

[out] Variable to get the variance.

skewness

[out] Variable to get the skewness.

kurtosis

[out] Variable to get the kurtosis.

error_code

[out] Variable to get the error code.

Return Value

Returns true if calculation of the moments has been successful, otherwise false.

Subfunctions

Group of functions that perform basic mathematical operations: calculation of the gamma function, beta function, factorial, exponential, logarithms with different bases, square root, etc.

They provide the ability to process both individual numeric values (real and integer) and arrays of such values (with output of the results to a separate or the original array).

Function	Description
<u>MathRandomNonZero</u>	Returns a random number with a floating point in the range from 0.0 to 1.0.
<u>MathMoments</u>	Calculates the first 4 moments of array elements: mean, variance, skewness, kurtosis.
<u>MathPowInt</u>	Raises a number to the specified integer power.
<u>MathFactorial</u>	Calculates the factorial of the specified integer.
<u>MathTrunc</u>	Calculates the integer part of the specified number or array elements.
<u>MathRound</u>	Rounds a number or an array of numbers to the specified number of decimal places.
<u>MathArctan2</u>	Calculates the angle, the tangent of which is equal to the ratio of the two specified numbers in the range of $[-\pi, \pi]$.
<u>MathGamma</u>	Calculates the value of the gamma function.
<u>MathGammaLog</u>	Calculates the logarithm of the gamma function.
<u>MathBeta</u>	Calculates the value of the beta function.
<u>MathBetaLog</u>	Calculates the logarithm of the beta function.
<u>MathBetaIncomplete</u>	Calculates the value of the incomplete beta function.
<u>MathGammaIncomplete</u>	Calculates the value of the incomplete gamma function.
<u>MathBinomialCoefficient</u>	Calculates the binomial coefficient.
<u>MathBinomialCoefficientLog</u>	Calculates the logarithm of the binomial coefficient.
<u>MathHypergeometric2F2</u>	Calculates the value of the hypergeometric function.
<u>MathSequence</u>	Generates a sequence based on values: the first element, the last element, the step of the sequence.

<u>MathSequenceByCount</u>	Generates a sequence based on values: the first element, the last element, the number of elements in the sequence.
<u>MathReplicate</u>	Generates a repeating sequence of values.
<u>MathReverse</u>	Generates an array of values with reverse order of elements.
<u>MathIdentical</u>	Compares two arrays of values and returns true if all elements match.
<u>MathUnique</u>	Generates an array with unique values only.
<u>MathQuickSortAscending</u>	Function for sorting in ascending order.
<u>MathQuickSortDescending</u>	Function for sorting in descending order.
<u>MathQuickSort</u>	Function for sorting.
<u>MathOrder</u>	Generates an array with permutation according to order of the array elements after sorting.
<u>MathBitwiseNot</u>	Calculates the result of bitwise NOT operation for array elements.
<u>MathBitwiseAnd</u>	Calculates the result of bitwise AND operation for elements of arrays.
<u>MathBitwiseOr</u>	Calculates the result of bitwise OR operation for elements of arrays.
<u>MathBitwiseXor</u>	Calculates the result of bitwise XOR operation for elements of arrays.
<u>MathBitwiseShiftL</u>	Calculates the result of bitwise SHL operation for array elements.
<u>MathBitwiseShiftR</u>	Calculates the result of bitwise SHR operation for array elements.
<u>MathCumulativeSum</u>	Generates an array with the cumulative sums.
<u>MathCumulativeProduct</u>	Generates an array with the cumulative products.
<u>MathCumulativeMin</u>	Generates an array with the cumulative minima.
<u>MathCumulativeMax</u>	Generates an array with the cumulative maxima.
<u>MathSin</u>	Calculates the values of the sin(x) function for array elements.
<u>MathCos</u>	Calculates the values of the cos(x) function for array elements.

<u>MathTan</u>	Calculates the values of the $\tan(x)$ function for array elements.
<u>MathArcsin</u>	Calculates the values of the $\arcsin(x)$ function for array elements.
<u>MathArccos</u>	Calculates the values of the $\arccos(x)$ function for array elements.
<u>MathArctan</u>	Calculates the values of the $\arctan(x)$ function for array elements.
<u>MathSinPi</u>	Calculates the values of the $\sin(\pi \cdot x)$ function for array elements.
<u>MathCosPi</u>	Calculates the values of the $\cos(\pi \cdot x)$ function for array elements.
<u>MathTanPi</u>	Calculates the values of the $\tan(\pi \cdot x)$ function for array elements.
<u>MathAbs</u>	Calculates the absolute values of array elements.
<u>MathCeil</u>	Returns the nearest larger integers for array elements.
<u>MathFloor</u>	Returns the nearest smaller integers for array elements.
<u>MathSqrt</u>	Calculates the square roots of array elements.
<u>MathExp</u>	Calculates the values of the $\exp(x)$ function for array elements.
<u>MathPow</u>	Calculates the values of the $\text{pow}(x, \text{power})$ function for array elements.
<u>MathLog</u>	Calculates the values of the $\log(x)$ function for array elements.
<u>MathLog2</u>	Calculates the logarithm to the base 2 for the array elements.
<u>MathLog10</u>	Calculates the logarithm to the base 10 for the array elements.
<u>MathDifference</u>	Generates an array with element differences of $y[i] = x[i + \text{lag}] - x[i]$.
<u>MathSample</u>	Generates a random sample from the array elements.
<u>MathTukeySummary</u>	Calculates the Tukey's five-number summary for the array elements.
<u>MathRange</u>	Calculates the minima and maxima of array elements.

<u>MathMin</u>	Returns the minimum value of all array elements.
<u>MathMax</u>	Returns the maximum value of all array elements.
<u>MathSum</u>	Returns the sum of array elements.
<u>MathProduct</u>	Returns the product of array elements.
<u>MathStandardDeviation</u>	Calculates the standard deviation of array elements.
<u>MathAverageDeviation</u>	Calculates the average absolute deviation of array elements.
<u>MathMedian</u>	Calculates the median value of array elements.
<u>MathMean</u>	Calculates the mean values of array elements.
<u>MathVariance</u>	Calculates the variance of the array elements.
<u>MathSkewness</u>	Calculates the skewness of the array elements.
<u>MathKurtosis</u>	Calculates the kurtosis of the array elements.
<u>MathLog1p</u>	Calculates the values of the $\log(1+x)$ function for array elements.
<u>MathExpml</u>	Calculates the values of the $\exp(x)-1$ function for array elements.
<u>MathSinh</u>	Calculates the values of the $\sinh(x)$ function for array elements.
<u>MathCosh</u>	Calculates the values of the $\cosh(x)$ function for array elements.
<u>MathTanh</u>	Calculates the values of the $\tanh(x)$ function for array elements.
<u>MathArcsinh</u>	Calculates the values of the $\operatorname{arsinh}(x)$ function for array elements.
<u>MathArccosh</u>	Calculates the values of the $\operatorname{arcosh}(x)$ function for array elements.
<u>MathArctanh</u>	Calculates the values of the $\operatorname{arctanh}(x)$ function for array elements.
<u>MathSignif</u>	Rounds a value to the specified number of digits in the mantissa.
<u>MathRank</u>	Calculates the ranks of array elements.
<u>MathCorrelationPearson</u>	Calculates the Pearson's correlation coefficient.
<u>MathCorrelationSpearman</u>	Calculates the Spearman's correlation coefficient.

<u>MathCorrelationKendall</u>	Calculates the Kendall's correlation coefficient.
<u>MathQuantile</u>	Calculates sample quantiles corresponding to the specified probabilities.
<u>MathProbabilityDensityEmpirical</u>	Calculates the empirical probability density function for random values.
<u>MathCumulativeDistributionEmpirical</u>	Calculates the empirical cumulative distribution function for random values.

MathRandomNonZero

Returns a random number with a floating point in the range from 0.0 to 1.0.

```
double MathRandomNonZero()
```

Return Value

Random number with a floating point in the range from 0.0 to 1.0.

MathMoments

Calculates the first 4 moments of array elements: mean, variance, skewness, kurtosis.

```
bool MathMoments (
    const double& array[],           // array of values
    double& mean,                   // variable for the mean
    double& variance,               // variable for the variance
    double& skewness,               // variable for the skewness
    double& kurtosis,               // variable for the kurtosis
    const int start=0,               // initial index
    const int count=WHOLE_ARRAY     // the number of elements
)
```

Parameters

array[]

[in] Array of values.

mean

[out] Variable for the mean (1st moment).

variance

[out] Variable for the variance (2nd moment).

skewness

[out] Variable for the skewness (3rd moment).

kurtosis

[out] Variable for the kurtosis (4th moment).

start=0

[in] Initial index for calculation.

count=WHOLE_ARRAY

[in] The number of elements for calculation.

Return Value

Returns true if the moments have been calculated successfully, otherwise false.

MathPowInt

Raises a number to the specified integer power.

```
double MathPowInt(  
    const double x,      // value of the number  
    const int    power   // power to raise to  
)
```

Parameters

x

[in] Double-precision floating-point number to be raised to the power.

power

[in] Integer specifying the power.

Return Value

The number *x*, raised to the specified power.

MathFactorial

Calculates the factorial of the specified integer.

```
double MathFactorial(  
    const int n    // value of the number  
)
```

Parameters

n

[in] Integer number, the factorial of which is to be calculated.

Return Value

The factorial of the number.

MathTrunc

Calculates the integer part of the specified number or array elements.

Version for working with a double-precision floating-point number:

```
double MathTrunc(  
    const double x           // value of the number  
)
```

Return Value

The integer part of the specified number.

Version for working with an array of double-precision floating-point numbers. The results are output to a new array:

```
bool MathTrunc(  
    const double& array[],    // array of values  
    double& result[]         // array of results  
)
```

Return Value

Returns true if successful, otherwise false.

Version for working with an array of double-precision floating-point numbers. The results are output to the original array:

```
bool MathTrunc(  
    double& array[]          // array of values  
)
```

Return Value

Returns true if successful, otherwise false.

Parameters

x

[in] Double-precision floating-point number, the integer part of which is to be obtained.

array[]

[in] Array of double-precision floating-point numbers, the integer parts of which are to be obtained.

array[]

[out] Array of output values.

result[]

[out] Array of output values.

MathRound

Rounds a double-precision floating-point number or an array of such numbers to the specified number of decimal places.

Version for rounding a double-precision floating-point number to the specified number of decimal places:

```
double MathRound(  
    const double x,           // value of the number  
    const int digits          // the number of decimal places  
)
```

Return Value

A number nearest to the *x* parameter, with the number of decimal places equal to *digits*.

Version for rounding an array of double-precision floating-point numbers to the specified number of decimal places. The results are output to a new array.

```
bool MathRound(  
    const double& array[],    // array of values  
    int digits,              // the number of decimal places  
    double& result[]         // array of results  
)
```

Return Value

Returns true if successful, otherwise false.

Version for rounding an array of double-precision floating-point numbers to the specified number of decimal places. The results are output to the original array.

```
bool MathRound(  
    double& array[],          // array of values  
    int digits                // the number of decimal places  
)
```

Return Value

Returns true if successful, otherwise false.

Parameters

x

[in] Double-precision floating-point number to be rounded.

digits

[in] The number of decimal places in the returned value.

array[]

[in] Array of double-precision floating-point numbers to be rounded.

array[]

[out] Array of output values.

```
result[]
```

[out] Array of output values.

MathArctan2

Returns the arctangent of the quotient of two arguments (x, y).

Version for working with the ratio of the two specified numbers (x, y):

```
double MathArctan2(
    const double    y,          // Y coordinate
    const double    x          // X coordinate
)
```

Return Value

Angle θ , measured in radians, so that $-\pi \leq \theta \leq \pi$ and $\tan(\theta) = y$ or x , where (x, y) is a point in a Cartesian coordinate system.

Version for working with the ratio of the element pairs from the x and y arrays:

```
bool MathArctan2(
    const double&    x[],        // array of x values
    const double&    y[],        // array of y values
    double&          result[]    // array of results
)
```

Return Value

Returns true if successful, otherwise false.

Parameters

y

[in] The Y coordinate of the point.

x

[in] The X coordinate of the point.

x[]

[in] Array of X coordinates of the points.

y[]

[in] Array of Y coordinates of the points.

result[]

[out] Array to output the results

Notes

Please note the following.

- For (x, y) in the quadrant 1, the return value will be: $0 < \theta < \pi/2$.
- For (x, y) in the quadrant 2, the return value will be: $\pi/2 < \theta \leq \pi$.
- For (x, y) in the quadrant 3, the return value will be: $-\pi < \theta < -\pi/2$.
- For (x, y) in the quadrant 4, the return value will be: $-\pi/2 < \theta < 0$.

The return value for the points outside these quadrants is indicated below.

- If y is 0 and x is not negative, then $\theta = 0$.
- If y is 0 and x is negative, then $\theta = \pi$.
- If y is a positive number, and x is 0, then $\theta = \pi/2$.
- If y is negative and x is 0, then $\theta = -\pi/2$.
- If y is 0 and x is 0, then $\theta = -\pi/2$.

If the value of the x or y parameter is NaN, or if the values of the x and y parameters are equal to the value PositiveInfinity or NegativeInfinity, the method returns the NaN value.

MathGamma

Calculates the value of the gamma function for the real argument x .

```
double MathGamma(  
    const double x      // argument of the function  
)
```

Parameters

x

[in] The real argument of the function.

Return Value

The value of the gamma function.

MathGammaLog

Calculates the logarithm of the gamma function for the real argument x.

```
double MathGammaLog(  
    const double x    // argument of the function  
)
```

Parameters

x

[in] The real argument of the function.

Return Value

Logarithm of the function.

MathBeta

Calculates the value of the beta function for the real arguments a and b.

```
double MathBeta(  
    const double a,      // the first argument of the function  
    const double b      // the second argument of the function  
)
```

Parameters

a

[in] The a argument of the function.

b

[in] The b argument of the function.

Return Value

Value of the function.

MathBetaLog

Calculates the logarithm of the beta function for the real arguments a and b.

```
double MathBetaLog(  
    const double a,      // the first argument of the function  
    const double b      // the second argument of the function  
)
```

Parameters

a

[in] The a argument of the function.

b

[in] The b argument of the function.

Return Value

Logarithm of the function.

MathBetaIncomplete

Calculates the value of the incomplete beta function.

```
double MathBetaIncomplete(  
    const double x,      // argument of the function  
    const double p,      // the first parameter of the function  
    const double q       // the second parameter of the function  
)
```

Parameters

x

[in] The argument of the function.

p

[in] The first parameter of the beta function, must be >0.0.

q

[in] The second parameter of the beta function, must be >0.0.

Return Value

Value of the function.

MathGammaIncomplete

Calculates the value of the incomplete gamma function.

```
double MathGammaIncomplete (  
    double x,           // argument of the function  
    double alpha        // parameter of the function  
)
```

Parameters

x

[in] The argument of the function.

alpha

[in] The parameter of the incomplete gamma function.

Return Value

Value of the function.

MathBinomialCoefficient

Calculates the binomial coefficient: $C(n,k)=n!/(k!(n-k)!)$.

```
long MathBinomialCoefficient(  
    const int n,          // the total number of elements  
    const int k           // the number of elements in combination  
)
```

Parameters

n

[in] The number of elements.

k

[in] The number of elements for each combination.

Return Value

The number of combinations of N choose K.

MathBinomialCoefficientLog

Calculates the logarithm of the binomial coefficient: $\text{Log}(C(n,k)) = \text{Log}(n! / (k! * (n-k)!))$

Version for integer arguments:

```
double MathBinomialCoefficientLog(  
    const int    n,          // the total number of elements  
    const int    k          // the number of elements in combination  
)
```

Version for real arguments:

```
double MathBinomialCoefficientLog(  
    const double n,          // the total number of elements  
    const double k          // the number of elements in combination  
)
```

Parameters

n

[in] The number of elements.

k

[in] The number of elements for each combination.

Return Value

The logarithm of $C(n,k)$.

MathHypergeometric2F2

Calculates the value of the Hypergeometric_2F2 (a, b, c, d, z) function using the Taylor's method.

```
double MathHypergeometric2F2(  
    const double a,      // the first parameter of the function  
    const double b,      // the second parameter of the function  
    const double c,      // the third parameter of the function  
    const double d,      // the fourth parameter of the function  
    const double z       // the fifth parameter of the function  
)
```

Parameters

a

[in] The first parameter of the function.

b

[in] The second parameter of the function.

c

[in] The third parameter of the function.

d

[in] The fourth parameter of the function.

z

[in] The fifth parameter of the function.

Return Value

Value of the function.

MathSequence

Generates a sequence of values based on the following values: the first element, the last element, the step of the sequence.

Version for working with real values:

```
bool MathSequence(  
    const double from,      // initial value  
    const double to,        // final value  
    const double step,      // step  
    double& result[]        // array of results  
)
```

Version for working with integer values:

```
bool MathSequence(  
    const int from,         // initial value  
    const int to,           // final value  
    const int step,         // step  
    int& result[]           // array of results  
)
```

Parameters

from

[in] The first value of the sequence

to

[in] The last value of the sequence

step

[in] The step of the sequence.

result[]

[out] Array to output the sequence.

Return Value

Returns true if successful, otherwise false.

MathSequenceByCount

Generates a sequence of values based on the following values: the first element, the last element, the number of elements in the sequence.

Version for working with real values:

```
bool MathSequenceByCount (
    const double from,      // initial value
    const double to,        // final value
    const int count,        // count
    double& result[]        // array of results
)
```

Version for working with integer values:

```
bool MathSequenceByCount (
    const int from,         // initial value
    const int to,           // final value
    const int count,        // count
    int& result[]           // array of results
)
```

Parameters

from

[in] The first value of the sequence.

to

[in] The last value of the sequence.

count

[in] The number of elements in the sequence.

result[]

[out] Array to output the sequence.

Return Value

Returns true if successful, otherwise false.

MathReplicate

Generates a repeating sequence of values.

Version for working with real values:

```
bool MathReplicate(  
    const double& array[],    // array of values  
    const int     count,      // number of repetitions  
    double&       result[]    // array of results  
)
```

Version for working with integer values:

```
bool MathReplicate(  
    const int&    array[],    // array of values  
    const int     count,      // number of repetitions  
    int&          result[]    // array of results  
)
```

Parameters

array[]

[in] Array for generating a sequence.

count

[in] The number of the array repetitions in the sequence.

result[]

[out] Array to output the sequence.

Return Value

Returns true if successful, otherwise false.

MathReverse

Generates an array of values with reverse order of elements.

Version for working with real values and with output of the results to a new array:

```
bool MathReverse (
    const double& array[],      // array of values
    double& result[]           // array of results
)
```

Version for working with integer values and with output of the results to a new array:

```
bool MathReverse (
    const int& array[],         // array of values
    int& result[]              // array of results
)
```

Version for working with real values and with output of the results to the original array.

```
bool MathReverse (
    double& array[]            // array of values
)
```

Version for working with integer values and with output of the results to the original array:

```
bool MathReverse (
    int& array[]               // array of values
)
```

Parameters

array[]
[in] Array of values.

array[]
[out] Output array with the reverse order of values.

result[]
[out] Output array with the reverse order of values.

Return Value

Returns true if successful, otherwise false.

MathIdentical

Compares two arrays of values and returns true if all elements match.

Version for working with arrays of real values:

```
bool MathIdentical(  
    const double& array1[],    // the first array of values  
    const double& array2[]    // the second array of values  
)
```

Version for working with arrays of integer values:

```
bool MathIdentical(  
    const int& array1[],      // the first array of values  
    const int& array2[]      // the second array of values  
)
```

Parameters

array1[]

[in] The first array to compare.

array2[]

[in] The second array to compare.

Return Value

Returns true if the arrays are equal, otherwise false.

MathUnique

Generates an array with unique values only.

Version for working with real values:

```
bool MathUnique(  
    const double& array[], // array of values  
    double& result[] // array of results  
)
```

Version for working with integer values:

```
bool MathUnique(  
    const int& array[], // array of values  
    int& result[] // array of results  
)
```

Parameters

array[]

[in] The source array.

result[]

[out] Array to output the unique values.

Return Value

Returns true if successful, otherwise false.

MathQuickSortAscending

The function for the simultaneous ascending sorting of the `array[]` and `indices[]` arrays using the QuickSort algorithm.

```
void MathQuickSortAscending(  
    double& array[],    // array of values  
    int& indices[],    // array of indexes  
    int first,          // initial value  
    int last            // final value  
)
```

Parameters

array[]

[in][out] Array to be sorted.

indices[]

[in][out] Array to store the indexes of the original array.

first

[in] Index of the element to start sorting from.

last

[in] Index of the element to stop sorting at.

MathQuickSortDescending

The function for the simultaneous descending sorting of the `array[]` and `indices[]` arrays using the QuickSort algorithm.

```
void MathQuickSortDescending(  
    double& array[],    // array of values  
    int& indices[],    // array of indexes  
    int first,          // initial value  
    int last            // final value  
)
```

Parameters

array[]

[in][out] Array to be sorted.

indices[]

[in][out] Array to store the indexes of the original array.

first

[in] Index of the element to start sorting from.

last

[in] Index of the element to stop sorting at.

MathQuickSort

The function for the simultaneous sorting of the `array[]` and `indices[]` arrays using the QuickSort algorithm.

```
void MathQuickSort(  
    double& array[], // array of values  
    int& indices[], // array of indexes  
    int first, // initial value  
    int last, // final value  
    int mode // direction  
)
```

Parameters

array[]

[in][out] Array to be sorted.

indices[]

[in][out] Array to store the indexes of the original array.

first

[in] Index of the element to start sorting from.

last

[in] Index of the element to stop sorting at.

mode

[in] Direction of sorting (>0 ascending; otherwise, descending).

MathOrder

Generates an integer array with permutation according to order of the array elements after sorting.

Version for working with an array of real values:

```
bool MathOrder(  
    const double& array[], // array of values  
    int& result[] // array of results  
)
```

Version for working with an array of integer values:

```
bool MathOrder(  
    const int& array[], // array of values  
    int& result[] // array of results  
)
```

Parameters

array[]

[in] Array of values.

result[]

[out] Array to output the sorted indexes.

Return Value

Returns true if successful, otherwise false.

MathBitwiseNot

Calculates the result of bitwise NOT operation for array elements.

Version with output of the results to a new array:

```
bool MathBitwiseNot(  
    const int& array[], // array of values  
    int& result[] // array of results  
)
```

Version with output of the results to the original array:

```
bool MathBitwiseNot(  
    int& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

array[]
[out] Array of output values.

result[]
[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

MathBitwiseAnd

Calculates the result of bitwise AND operation for specified arrays.

```
bool MathBitwiseAnd(  
    const int& array1[], // the first array of values  
    const int& array2[], // the second array of values  
    int& result[] // array of results  
)
```

Parameters

array1[]

[in] The first array of values.

array2[]

[in] The second array of values.

result[]

[out] Array to output the results.

Return Value

Returns true if successful, otherwise false.

MathBitwiseOr

Calculates the result of bitwise OR operation for specified arrays.

```
bool MathBitwiseOr(  
    const int& array1[], // the first array of values  
    const int& array2[], // the second array of values  
    int& result[] // array of results  
)
```

Parameters

array1[]

[in] The first array of values.

array2[]

[in] The second array of values.

result[]

[out] Array to output the results.

Return Value

Returns true if successful, otherwise false.

MathBitwiseXor

Calculates the result of bitwise XOR operation for specified arrays.

```
bool MathBitwiseXor(  
    const int& array1[], // the first array of values  
    const int& array2[], // the second array of values  
    int& result[] // array of results  
)
```

Parameters

array1[]

[in] The first array of values.

array2[]

[in] The second array of values.

result[]

[out] Array to output the results.

Return Value

Returns true if successful, otherwise false.

MathBitwiseShiftL

Calculates the result of bitwise SHL (bitwise shift left) operation for array elements.

Version with output of the results to a new array:

```
bool MathBitwiseShiftL(  
    const int& array[],    // array of values  
    const int  n,          // shift value  
    int&       result[]    // array of results  
)
```

Version with output of the results to the original array:

```
bool MathBitwiseShiftL(  
    int&       array[],    // array of values  
    const int  n           // shift value  
)
```

Parameters

array[]

[in] Array of values.

n

[in] The number of bits to shift.

array[]

[out] Array of output values.

result[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

MathBitwiseShiftR

Calculates the result of bitwise SHR (bitwise shift right) operation for array elements.

Version with output of the results to a new array:

```
bool MathBitwiseShiftR(  
    const int& array[],    // array of values  
    const int  n,          // shift value  
    int&       result[]    // array of results  
)
```

Version with output of the results to the original array:

```
bool MathBitwiseShiftR(  
    int&       array[],    // array of values  
    const int  n           // shift value  
)
```

Parameters

array[]

[in] Array of values.

n

[in] The number of bits to shift.

array[]

[out] Array of output values.

result[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

MathCumulativeSum

Generates an array with the cumulative sums.

Version with output of the results to a new array:

```
bool MathCumulativeSum(  
    const double& array[], // array of values  
    double& result[] // array of results  
)
```

Version with output of the results to the original array:

```
bool MathCumulativeSum(  
    double& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

array[]
[out] Array of output values.

result[]
[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

MathCumulativeProduct

Generates an array with the cumulative products.

Version with output of the results to a new array:

```
bool MathCumulativeProduct(  
    const double& array[], // array of values  
    double& result[] // array of results  
)
```

Version with output of the results to the original array:

```
bool MathCumulativeProduct(  
    double& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

result[]
[out] Array of output values.

array[]
[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

MathCumulativeMin

Generates an array with the cumulative minima.

Version with output of the results to a new array:

```
bool MathCumulativeMin(  
    const double& array[], // array of values  
    double& result[] // array of results  
)
```

Version with output of the results to the original array:

```
bool MathCumulativeMin(  
    double& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

result[]
[out] Array of output values.

array[]
[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

MathCumulativeMax

Generates an array with the cumulative maxima.

Version with output of the results to a new array:

```
bool MathCumulativeMax(  
    const double& array[], // array of values  
    double& result[] // array of results  
)
```

Version with output of the results to the original array:

```
bool MathCumulativeMax(  
    double& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

result[]
[out] Array of output values.

array[]
[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

MathSin

Calculates the values of the $\sin(x)$ function for array elements.

Version with output of the results to a new array:

```
bool MathSin(  
    const double& array[], // array of values  
    double& result[] // array of results  
)
```

Version with output of the results to the original array:

```
bool MathSin(  
    double& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

result[]
[out] Array of output values.

array[]
[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

MathCos

Calculates the values of the $\cos(x)$ function for array elements.

Version with output of the results to a new array:

```
bool MathCos (
    const double& array[], // array of values
    double& result[] // array of results
)
```

Version with output of the results to the original array:

```
bool MathCos (
    double& array[] // array of values
)
```

Parameters

array[]
[in] Array of values.

result[]
[out] Array of output values.

array[]
[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

MathTan

Calculates the values of the $\tan(x)$ function for array elements.

Version with output of the results to a new array:

```
bool MathTan(  
    const double& array[], // array of values  
    double& result[] // array of results  
)
```

Version with output of the results to the original array:

```
bool MathTan(  
    double& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

result[]
[out] Array of output values.

array[]
[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

MathArcsin

Calculates the values of the arcsin(x) function for array elements.

Version with output of the results to a new array:

```
bool MathArcsin(  
    const double& array[], // array of values  
    double& result[] // array of results  
)
```

Version with output of the results to the original array:

```
bool MathArcsin(  
    double& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

result[]
[out] Array of output values.

array[]
[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

MathArccos

Calculates the values of the $\arccos(x)$ function for array elements.

Version with output of the results to a new array:

```
bool MathArccos (
    const double&   array[],    // array of values
    double&         result[]    // array of results
)
```

Version with output of the results to the original array:

```
bool MathArccos (
    double&         array[]     // array of values
)
```

Parameters

array[]
[in] Array of values.

result[]
[out] Array of output values.

array[]
[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

MathArctan

Calculates the values of the $\arctan(x)$ function for array elements.

Version with output of the results to a new array:

```
bool MathArctan(  
    const double& array[], // array of values  
    double& result[] // array of results  
)
```

Version with output of the results to the original array:

```
bool MathArctan(  
    double& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

result[]
[out] Array of output values.

array[]
[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

MathSinPi

Calculates the values of the $\sin(\pi \cdot x)$ function for array elements.

Version with output of the results to a new array:

```
bool MathSinPi(  
    const double& array[], // array of values  
    double& result[] // array of results  
)
```

Version with output of the results to the original array:

```
bool MathSinPi(  
    double& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

result[]
[out] Array of output values.

array[]
[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

MathCosPi

Calculates the values of the $\cos(\pi \cdot x)$ function for array elements.

Version with output of the results to a new array:

```
bool MathCosPi(  
    const double& array[], // array of values  
    double& result[] // array of results  
)
```

Version with output of the results to the original array:

```
bool MathCosPi(  
    double& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

result[]
[out] Array of output values.

array[]
[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

MathTanPi

Calculates the values of the $\tan(\pi \cdot x)$ function for array elements.

Version with output of the result to a new array:

```
bool MathTanPi(  
    const double& array[], // array of values  
    double& result[] // array of results  
)
```

Version with output of the result to the original array:

```
bool MathTanPi(  
    double& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

result[]
[out] Array of output values.

array[]
[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

MathAbs

Calculates the absolute values of array elements.

Version with output of the results to a new array:

```
bool MathAbs (
    const double& array[], // array of values
    double& result[] // array of results
)
```

Version with output of the results to the original array:

```
bool MathAbs (
    double& array[] // array of values
)
```

Parameters

array[]
[in] Array of values.

result[]
[out] Array of output values.

array[]
[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

MathCeil

Returns the nearest larger integers for array elements.

Version with output of the results to a new array:

```
bool MathCeil(  
    const double& array[], // array of values  
    double& result[] // array of results  
)
```

Version with output of the results to the original array:

```
bool MathCeil(  
    double& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

result[]
[out] Array of output values.

array[]
[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

MathFloor

Returns the nearest smaller integers for array elements.

Version with output of the results to a new array:

```
bool MathFloor(  
    const double& array[], // array of values  
    double& result[] // array of results  
)
```

Version with output of the results to the original array:

```
bool MathFloor(  
    double& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

result[]
[out] Array of output values.

array[]
[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

MathSqrt

Calculates the square roots of array elements.

Version with output of the results to a new array:

```
bool MathSqrt(  
    const double& array[], // array of values  
    double& result[] // array of results  
)
```

Version with output of the results to the original array:

```
bool MathSqrt(  
    double& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

result[]
[out] Array of output values.

array[]
[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

MathExp

Calculates the values of the $\exp(x)$ function for array elements.

Version with output of the results to a new array:

```
bool MathExp(  
    const double& array[], // array of values  
    double& result[] // array of results  
)
```

Version with output of the results to the original array:

```
bool MathExp(  
    double& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

result[]
[out] Array of output values.

array[]
[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

MathPow

Calculates the values of the pow(x, power) function for array elements.

Version with output of the results to a new array:

```
bool MathPow(  
    const double& array[],    // array of values  
    const double power,      // power  
    double& result[]         // array of results  
)
```

Version with output of the results to the original array:

```
bool MathPow(  
    double& array[],          // array of values  
    const double power        // power  
)
```

Parameters

array[]

[in] Array of values.

result[]

[out] Array of output values.

array[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

MathLog

Calculates the values of the $\log(x)$ function for array elements.

Version for calculating the natural logarithm with output of the results to a new array.

```
bool MathLog(  
    const double& array[],      // array of values  
    double& result[]           // array of results  
)
```

Version for calculating the natural logarithm with output of the results to the original array.

```
bool MathLog(  
    double& array[]            // array of values  
)
```

Version for calculating the logarithm to a specified base with output of the results to a new array.

```
bool MathLog(  
    const double& array[],      // array of values  
    const double base,          // base of the logarithm  
    double& result[]           // array of results  
)
```

Version for calculating the logarithm to a specified base with output of the results to the original array.

```
bool MathLog(  
    double& array[],            // array of values  
    const double base           // base of the logarithm  
)
```

Parameters

array[]

[in] Array of values.

base

[in] The base of the logarithm.

array[]

[out] Array of output values.

result[]

[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

MathLog2

Calculates the logarithm to the base 2 for the array elements.

Version with output of the results to a new array:

```
bool MathLog2(  
    const double& array[], // array of values  
    double& result[] // array of results  
)
```

Version with output of the results to the original array:

```
bool MathLog2(  
    double& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

result[]
[out] Array of output values.

array[]
[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

MathLog10

Calculates the logarithm to the base 10 for the array elements.

Version with output of the results to a new array:

```
bool MathLog10(  
    const double& array[], // array of values  
    double& result[] // array of results  
)
```

Version with output of the results to the original array:

```
bool MathLog10(  
    double& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

result[]
[out] Array of output values.

array[]
[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

MathLog1p

Calculates the values of the $\log(1+x)$ function for array elements.

Version with output of the results to a new array:

```
bool MathLog1p(  
    const double& array[], // array of values  
    double& result[] // array of results  
)
```

Version with output of the results to the original array:

```
bool MathLog1p(  
    double& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

result[]
[out] Array of output values.

array[]
[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

MathDifference

Generates an array with element differences of $y[i]=x[i+lag]-x[i]$.

Version for a single generation of an array of real values:

```
bool MathDifference(
    const double &array[], // array of values
    const int    lag,      // lag
    double       &result[] // array of results
)
```

Version for a single generation of an array of integer values:

```
bool MathDifference(
    const int    &array[], // array of values
    const int    lag,      // lag
    int          &result[] // array of results
)
```

Version for iterated generation of an array of real values (the number of iterations is set in the input parameters):

```
bool MathDifference(
    const double &array[], // array of values
    const int    lag,      // lag
    const int    differences, // number of iterations
    double       &result[] // array of results
)
```

Version for iterated generation of an array of integer values (the number of iterations is set in the input parameters):

```
bool MathDifference(
    const int&    array[], // array of values
    const int    lag,      // lag
    const int    differences, // number of iterations
    int&         result[] // array of results
)
```

Parameters

array[]
[in] Array of values.

lag
[in] Lag parameter.

differences
[in] The number of iterations.

result[]

[out] Array to output the results.

Return Value

Returns true if successful, otherwise false.

MathSample

Generates a random sample from the array elements.

Version for working with an array of real values:

```
bool MathSample(  
    const double& array[],           // array of values  
    const int     count,             // count  
    double&       result[]          // array of results  
)
```

Version for working with an array of integer values:

```
bool MathSample(  
    const int&    array[],           // array of values  
    const int     count,             // count  
    int&          result[]          // array of results  
)
```

Version for working with an array of real values. It is possible to obtain a sample with replacement:

```
bool MathSample(  
    const double& array[],           // array of values  
    const int     count,             // count  
    const bool    replace,           // flag  
    double&       result[]          // array of results  
)
```

Version for working with an array of integer values. It is possible to obtain a sample with replacement:

```
bool MathSample(  
    const int&    array[],           // array of values  
    const int     count,             // count  
    const bool    replace,           // flag  
    int&          result[]          // array of results  
)
```

Version for working with an array of real values, for which the probabilities of sampling are defined.

```
bool MathSample(  
    const double& array[],           // array of values  
    double&       probabilities[],  // array of probabilities  
    const int     count,             // count  
    double&       result[]          // array of results  
)
```

Version for working with an array of integer values, for which the probabilities of sampling are defined.

```

bool MathSample(
    const int&    array[],           // array of values
    double&       probabilities[],   // array of probabilities
    const int     count,             // count
    int&          result[]           // array of results
)

```

Version for working with an array of real values, for which the probabilities of sampling are defined. It is possible to obtain a sample with replacement:

```

bool MathSample(
    const double& array[],           // array of values
    double&       probabilities[],   // array of probabilities
    const int     count,             // count
    const bool    replace,           // flag
    double&       result[]           // array of results
)

```

Version for working with an array of integer values, for which the probabilities of sampling are defined. It is possible to obtain a sample with replacement:

```

bool MathSample(
    const int&    array[],           // array of values
    double&       probabilities[],   // array of probabilities
    const int     count,             // count
    const bool    replace,           // flag
    int&          result[]           // array of results
)

```

Parameters

array[]

[in] Array of integer values.

probabilities[]

[in] Array of probabilities for sampling the elements.

count

[in] The number of elements.

replace

[in] Parameter that allows sampling with replacement.

result[]

[out] Array to output the results.

Return Value

Returns true if successful, otherwise false.

Note

The `replace=true` argument allows performing random sampling of the elements with replacement back to the original sequence.

MathTukeySummary

Calculates the Tukey's five-number summary (minimum, lower quartile, median, upper quartile, maximum) for the array elements.

```
bool MathTukeySummary(  
    const double& array[],           // array of values  
    const bool    removeNAN,        // flag  
    double&       minimum,          // minimum value  
    double&       lower_hinge,      // lower quartile  
    double&       median,           // median value  
    double&       upper_hinge,      // upper quartile  
    double&       maximum           // maximum value  
)
```

Parameters

array[]

[in] Array of real values.

removeNAN

[in] Flag that indicates if non-numeric values are to be removed.

minimum

[out] Variable to store the minimum value.

lower_hinge

[out] Variable to store the lower quartile.

median

[out] Variable to store the median value.

upper_hinge

[out] Variable to store the upper quartile.

maximum

[out] Variable to store the maximum value.

Return Value

Returns true if successful, otherwise false.

MathRange

Calculates the minima and maxima of array elements.

```
bool MathRange(  
    const double& array[], // array of values  
    double& min,           // minimum value  
    double& max            // maximum value  
)
```

Parameters

array[]
[in] Array of values.

min
[out] Variable to store the minimum value.

max
[out] Variable to store the maximum value.

Return Value

Returns true if successful, otherwise false.

MathMin

Returns the minimum value of all array elements.

```
double MathMin(  
    const double& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

Return Value

The minimum value.

MathMax

Returns the maximum value of all array elements.

```
double MathMax(  
    const double& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

Return Value

The maximum value.

MathSum

Returns the sum of array elements.

```
double MathSum(  
    const double& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

Return Value

The sum of the elements.

MathProduct

Returns the product of array elements.

```
double MathProduct(  
    const double& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

Return Value

The product of the elements.

MathStandardDeviation

Calculates the standard deviation of array elements.

```
double MathStandardDeviation(  
    const double& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

Return Value

Standard deviation.

MathAverageDeviation

The function calculates the average absolute deviation of array elements.

```
double MathAverageDeviation(  
    const double& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

Return Value

The average absolute deviation of array elements.

MathMedian

Calculates the median value of array elements.

```
double MathMedian(  
    double& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

Return Value

The median value.

MathMean

Calculates the mean values of array elements.

```
double MathMean(  
    const double& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

Return Value

The mean value.

MathVariance

The function calculates the variance (second moment) of array elements.

```
double MathVariance(  
    const double& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

Return Value

Value of the variance.

MathSkewness

The function calculates the skewness (third moment) of array elements.

```
double MathSkewness(  
    const double& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

Return Value

Skewness.

MathKurtosis

The function calculates the kurtosis (fourth moment) of array elements.

```
double MathKurtosis(  
    const double& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

Return Value

Kurtosis.

MathExpm1

Calculates the values of the $\exp(x)-1$ function for array elements.

Version with output of the results to a new array:

```
bool MathExpm1 (
    const double& array[], // array of values
    double& result[] // array of results
)
```

Version with output of the results to the original array:

```
bool MathExpm1 (
    double& array[] // array of values
)
```

Parameters

array[]
[in] Array of values.

result[]
[out] Array of output values.

array[]
[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

MathSinh

Calculates the values of the $\sinh(x)$ function for array elements.

Version with output of the results to a new array:

```
bool MathSinh(  
    const double& array[], // array of values  
    double& result[] // array of results  
)
```

Version with output of the results to the original array:

```
bool MathSinh(  
    double& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

result[]
[out] Array of output values.

array[]
[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

MathCosh

Calculates the values of the cosh(x) function for array elements.

Version with output of the results to a new array:

```
bool MathCosh(  
    const double& array[], // array of values  
    double& result[] // array of results  
)
```

Version with output of the results to the original array:

```
bool MathCosh(  
    double& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

result[]
[out] Array of output values.

array[]
[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

MathTanh

Calculates the values of the $\tanh(x)$ function for array elements.

Version with output of the results to a new array:

```
bool MathTanh(  
    const double& array[], // array of values  
    double& result[] // array of results  
)
```

Version with output of the results to the original array:

```
bool MathTanh(  
    double& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

result[]
[out] Array of output values.

array[]
[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

MathArcsinh

Calculates the values of the $\operatorname{arsinh}(x)$ function for array elements.

Version with output of the results to a new array:

```
bool MathArcsinh(  
    const double& array[], // array of values  
    double& result[] // array of results  
)
```

Version with output of the results to the original array:

```
bool MathArcsinh(  
    double& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

result[]
[out] Array of output values.

array[]
[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

MathArccosh

Calculates the values of the arccosh(x) function for array elements.

Version with output of the results to a new array:

```
bool MathArccosh(  
    const double& array[], // array of values  
    double& result[] // array of results  
)
```

Version with output of the results to the original array:

```
bool MathArccosh(  
    double& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

result[]
[out] Array of output values.

array[]
[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

MathArctanh

Calculates the values of the $\operatorname{arctanh}(x)$ function for array elements.

Version with output of the results to a new array:

```
bool MathArctanh(  
    const double& array[], // array of values  
    double& result[] // array of results  
)
```

Version with output of the results to the original array:

```
bool MathArctanh(  
    double& array[] // array of values  
)
```

Parameters

array[]
[in] Array of values.

result[]
[out] Array of output values.

array[]
[out] Array of output values.

Return Value

Returns true if successful, otherwise false.

MathSignif

Rounds a value to the specified number of digits in the mantissa.

Version for working with a real value:

```
double MathSignif(  
    const double x,           // value  
    const int    digits       // number of decimal places  
)
```

Return Value

The rounded value.

Version for working with an array of real values and with output of the results to a separate array:

```
bool MathSignif(  
    const double& array[],    // array of values  
    int          digits,      // number of decimal places  
    double       result[]     // array of results  
)
```

Return Value

Returns true if successful, otherwise false.

Version for working with an array of real values and with output of the results to the original array:

```
bool MathSignif(  
    double&       array[],    // array of values  
    int          digits       // number of decimal places  
)
```

Return Value

Returns true if successful, otherwise false.

Parameters

x

[in] Real value to be rounded.

digits

[in] Number of decimal places.

array[]

[in] Array of real values.

array[]

[out] Array of output values.

result[]

[out] Array of output values.

MathRank

Calculates the ranks of array elements.

Version for working with an array of real values:

```
bool MathRank(  
    const double& array[], // array of values  
    double& rank[] // array of ranks  
)
```

Version for working with an array of integer values:

```
bool MathRank(  
    const int& array[], // array of values  
    double& rank[] // array of ranks  
)
```

Parameters

array[]

[in] Array of values.

rank[]

[out] Array to output the ranks.

Return Value

Returns true if successful, otherwise false.

MathCorrelationPearson

Calculates the Pearson's correlation coefficient.

Version for working with arrays of real values:

```
bool MathCorrelationPearson(  
    const double& array1[], // the first array of values  
    const double& array2[], // the second array of values  
    double& r               // correlation coefficient  
)
```

Version for working with arrays of integer values:

```
bool MathCorrelationPearson(  
    const int& array1[], // the first array of values  
    const int& array2[], // the second array of values  
    double& r            // correlation coefficient  
)
```

Parameters

array1[]

[in] The first array of values.

array2[]

[in] The second array of values.

r

[out] Variable to store the correlation coefficient.

Return Value

Returns true if successful, otherwise false.

MathCorrelationSpearman

Calculates the Spearman's correlation coefficient.

Version for working with arrays of real values:

```
bool MathCorrelationSpearman(  
    const double& array1[], // the first array of values  
    const double& array2[], // the second array of values  
    double& r               // correlation coefficient  
)
```

Version for working with arrays of integer values:

```
bool MathCorrelationSpearman(  
    const int& array1[], // the first array of values  
    const int& array2[], // the second array of values  
    double& r           // correlation coefficient  
)
```

Parameters

array1[]

[in] The first array of values.

array2[]

[in] The second array of values.

r

[out] Variable to store the correlation coefficient.

Return Value

Returns true if successful, otherwise false.

MathCorrelationKendall

Calculates the Kendall's correlation coefficient.

Version for working with arrays of real values:

```
bool MathCorrelationKendall(  
    const double& array1[], // the first array of values  
    const double& array2[], // the second array of values  
    double& tau           // correlation coefficient  
)
```

Version for working with arrays of integer values:

```
bool MathCorrelationKendall(  
    const int& array1[], // the first array of values  
    const int& array2[], // the second array of values  
    double& tau          // correlation coefficient  
)
```

Parameters

array1[]

[in] The first array of values.

array2[]

[in] The second array of values.

tau

[out] Variable to store the correlation coefficient.

Return Value

Returns true if successful, otherwise false.

MathQuantile

Calculates sample quantiles corresponding to the specified probabilities: $Q[i](p) = (1 - \text{gamma}) * x[j] + \text{gamma} * x[j+1]$

```
bool MathQuantile(  
    const double& array[],      // array of values  
    const double& probs[],      // array of probabilities  
    double& quantile[]          // array to output the quantiles  
)
```

Parameters

array[]

[in] Array of values.

probs[]

[in] Array of probabilities.

quantile[]

[out] Array to output the quantiles.

Return Value

Returns true if successful, otherwise false.

MathProbabilityDensityEmpirical

The function calculates the empirical probability density function (pdf) for random values from an array.

```
bool MathProbabilityDensityEmpirical(  
    const double& array[], // array of random values  
    const int count, // the number of pairs  
    double& x[], // array of x values  
    double& pdf[] // array of pdf values  
)
```

Parameters

array[]

[in] Array of random values.

count

[in] The number of (x, pdf(x)) pairs.

x[]

[out] Array to output the x values.

pdf[]

[out] Array to output the pdf(x) values.

Return Value

Returns true if successful, otherwise false.

MathCumulativeDistributionEmpirical

The function calculates the empirical cumulative distribution function (cdf) for random values from an array.

```
bool MathCumulativeDistributionEmpirical(  
    const double& array[], // array of random values  
    const int count, // the number of pairs  
    double& x[], // array of x values  
    double& cdf[] // array of cdf values  
)
```

Parameters

array[]

[in] Array of random values.

count

[in] The number of (x, cdf(x)) pairs.

x[]

[out] Array to output the x values.

cdf[]

[out] Array to output the cdf(x) values.

Return Value

Returns true if successful, otherwise false.

Fuzzy is a library for working with fuzzy logic

Fuzzy logic is a synthesis of the traditional Aristotelian logic when truth is marked as a linguistic variable. Fuzzy logic, equivalent to classical logic, has its own fuzzy logic operations on fuzzy sets defined. There are the same operations for fuzzy sets as well as for ordinary sets, only their calculation is by far more difficult. We should also note that the composition of fuzzy sets constitutes as a fuzzy set.

The main principles of fuzzy logic, setting it apart from classical logic, are the maximum proximity to the reflection of reality and a high level of subjectivity, which can lead to significant errors in calculations.

Fuzzy model (or system) is a mathematical model whose calculation is based on fuzzy logic. Construction of such models is applicable when the subject of study has a weak formalization and its exact mathematical description is too complex or unknown. The quality of these models' output values (error model) directly depends only on the Expert Advisor, which set up this model. The best option to minimize errors is to draw the most complete and comprehensive model and subsequently adjust it with machine learning on a large training set.

The progress of a model construction can be divided into three main stages:

1. Definition of input and output characteristics of a model.
2. Building a knowledge base.
3. Selecting one of the methods of fuzzy inference ([Mamdani](#) or [Sugeno](#)).

The first stage directly effects the consequent two and determines the future operation of the model. A knowledge base or, as sometimes called, [rule](#) base is a set of fuzzy rules type: "if, then" that define the relationship between inputs and outputs of the examined object. The number of rules in the system is not limited and is also determined by the Expert Advisor. The generalized format of fuzzy rules is as follows:

If rule condition, then rule conclusion.

Rule condition describes the current state of the object, and rule conclusion — how this condition affects the object. General view of conditions and conclusions cannot be selected because they are determined by a fuzzy inference.

Each rule in the system has its weight — this characteristic defines the importance of a rule in the model. Weighting factors are assigned to a rule within range [0, 1]. In many examples with fuzzy models, which can be found in the relevant literature, weight data is not specified, but it does not mean that it is not present. In fact, in such case for each rule from the database, the weight is fixed and equals unity. There can be two types of terms and conclusions for each rule:

1. simple — includes one [fuzzy variable](#);
2. complex — includes several fuzzy variables.

Depending on the created knowledge base, the system of fuzzy inference is determined for a model. Fuzzy logical inference is a receipt of conclusion in form of a fuzzy set corresponding to the current value of the inputs with use of knowledge base and fuzzy operations. The two main types of fuzzy inference are Mamdani and Sugeno.

Membership functions

A **membership function** is a function that allows to calculate the membership degree of a random element of the universal set to a fuzzy set. Consequently, the domain of a membership function should be within the range [0, 1].

In most cases, the membership function is continuous and monotonic.

Classes of membership functions	Description
<u>CConstantMembershipFunction</u>	Class for implementing a membership function as a straight line in parallel with the coordinate axis
<u>CCompositeMembershipFunction</u>	Class for implementing a composition of membership functions
<u>CDifferencTwoSigmoidalMembershipFunction</u>	Class for implementing the membership function in the form of a difference between two sigmoid functions with the A1, A2, C1 and C2 parameters
<u>CGeneralizedBellShapedMembershipFunction</u>	Class for implementing a generalized bell-shaped membership function with A, B and C parameters
<u>CNormalCombinationMembershipFunction</u>	Class for implementing a two-sided Gaussian membership function with the B1, B2, Sigma1 and Sigma2 parameters
<u>CNormalMembershipFunction</u>	Class for implementing a symmetrical Gaussian membership function with the B and Sigma parameters
<u>CP_ShapedMembershipFunction</u>	Class for implementing a pi-shaped membership function with the A, B, C and D parameters
<u>CProductTwoSigmoidalMembershipFunction</u>	Class for implementing the membership function in the form of a product of two sigmoid functions with the A1, A2, C1 and C2 parameters
<u>CS_ShapedMembershipFunction</u>	Class for implementing an S-like membership function with the A and B parameters
<u>CTrapezoidMembershipFunction</u>	Class for implementing a trapezoidal membership function with the X1, X2, X3 and X4 parameters
<u>CTriangularMembershipFunction</u>	Class for implementing a triangle membership function with the X1, X2 and X3 parameters
<u>CSigmoidalMembershipFunction</u>	Class for implementing a sigmoid membership function with the A and C parameters

<u>CZ_ShapedMembershipFunction</u>	Class for implementing a z-like membership function with the A and B parameters.
<u>IMembershipFunction</u>	Basic class for all membership function classes.

CConstantMembershipFunction

Class for implementing a membership function as a straight line in parallel with the coordinate axis.

Description

The function is described by the equation:

$y(x)=c$

Therefore, the membership degree for the function is the same along the entire numerical axis and is equal to the parameter specified in the constructor.

A [sample code](#) for plotting a chart is displayed below.

Declaration

```
class CConstantMembershipFunction : public IMembershipFunction
```

Title

```
#include <Math\Fuzzy\membershipfunction.mqh>
```

Inheritance hierarchy

- [CObject](#)
- [IMembershipFunction](#)
- CConstantMembershipFunction

Class methods

Class method	Description
GetValue	Calculates the value of the membership function by a specified argument.

Methods inherited from class CObject

Prev, Prev, Next, Next, [Save](#), [Load](#), [Type](#), [Compare](#)

Example

```
//+-----+
//|                                     ConstantMembershipFunction.mq5 |

graphic.YAxis().Max(1.1);
graphic.YAxis().DefaultStep(0.2);
//--- plot
```

```
graphic.CurvePlotAll();  
graphic.Update();  
}
```

GetValue

Calculates the value of the membership function by a specified argument.

```
double GetValue(  
    const double x    // membership function argument  
)
```

Parameters

x

[in] Membership function argument.

Return Value

Membership function value.

CCompositeMembershipFunction

Class for implementing a composition of membership functions.

Description

Composition of membership functions is a combination of two or more membership functions using a specified operator.

A [sample code](#) for plotting a chart is displayed below.

Declaration

```
class CCompositeMembershipFuncion : public IMembershipFunction
```

Title

```
#include <Math\Fuzzy\membershipfunction.mqh>
```

Inheritance hierarchy

- [CObject](#)
- [IMembershipFunction](#)
- CCompositeMembershipFunction

Class methods

Class method	Description
CompositionType	Sets the composition operator.
MembershipFunctions	Gets the list of membership functions.
GetValue	Calculates the value of the membership function by a specified argument.

Methods inherited from class CObject

//--- sets the Y-axis properties
graphic.YAxis().AutoScale(false);
graphic.YAxis().Min(0.0);
graphic.YAxis().Max(1.1);
graphic.YAxis().DefaultStep(0.2);
//--- plot
```

```
graphic.CurvePlotAll();  
graphic.Update();  
}
```

CompositionType

Sets the composition operator.

```
void CompositionType(  
    MfCompositionType value    // operator type  
)
```

Parameters

value

[in] Composition operator type.

Note

The following operator types are available:

- MinMF (minimum of functions)
- MaxMF (maximum of functions)
- ProdMF (product of functions)
- SumMF (sum of functions)

MembershipFunctions

Gets the list of membership functions included into a composition.

```
CList* MembershipFunctions(  
    void    // list of membership functions  
)
```

Return Value

List of membership functions.

GetValue

Calculates the value of the membership function by a specified argument.

```
double GetValue(  
    const x    // membership function argument  
)
```

Parameters

x

[in] Membership function argument.

Return Value

Membership function value.

CDifferencTwoSigmoidalMembershipFunction

Class for implementing the membership function in the form of a difference between two sigmoid functions with the A1, A2, C1 and C2 parameters.

Description

The function is based on a sigmoid curve. It allows creating membership functions with the values equal to 1 beginning with an argument value. Such functions are suitable if you need to set such linguistic terms as "short" or "long".

A [sample code](#) for plotting a chart is displayed below.

Declaration

```
class CDifferencTwoSigmoidalMembershipFunction : public IMembershipFunction
```

Title

```
#include <Math\Fuzzy\membershipfunction.mqh>
```

Inheritance hierarchy

[CObject](#)

[IMembershipFunction](#)

CDifferencTwoSigmoidalMembershipFunction

Class methods

Class method	Description
A1	Gets and sets the first membership function slope ratio.

A2	Gets and sets the second membership function slope ratio.
C1	Gets and sets the first membership function inflection coordinate parameter.
C2	Gets and sets the second membership function inflection coordinate parameter.
GetValue	Calculates the value of the membership function by a specified argument.

graphic.YAxis().DefaultStep(0.2);
//--- plot
graphic.CurvePlotAll();
graphic.Update();
}
```

A1 (Get method)

Gets the first membership function slope ratio.

```
double A1()
```

Return Value

Slope ratio value.

A1 (Set method)

Sets the first membership function slope ratio.

```
void A1(
    const double a1    // slope ratio value
)
```

Parameters

a1

[in] Slope ratio value.

A2 (Get method)

Gets the second membership function slope ratio.

```
double A2()
```

Return Value

Slope ratio value.

A2 (Set method)

Sets the second membership function slope ratio.

```
void A2(
```

```
const double a2      // slope ratio value  
)
```

Parameters

a2

[in] Slope ratio value.

C1 (Get method)

Gets the first membership function inflection coordinate parameter.

```
double C1()
```

Return Value

Inflection coordinate value.

C1 (Set method)

Sets the first membership function inflection coordinate parameter.

```
void C1(  
    const double c1      // inflection coordinate value  
)
```

Parameters

c1

[in] Inflection coordinate value.

C2 (Get method)

Gets the second membership function inflection coordinate parameter.

```
double C2()
```

Return Value

Inflection coordinate value.

C2 (Set method)

Sets the second membership function inflection coordinate parameter.

```
void C2(  
    const double c2      // inflection coordinate value  
)
```

Parameters

c2

[in] Inflection coordinate value.

GetValue

Calculates the value of the membership function by a specified argument.

```
double GetValue (  
    const double x      // membership function argument  
)
```

Parameters

x

[in] Membership function argument.

Return Value

Membership function value.

CGeneralizedBellShapedMembershipFunction

Class for implementing a generalized bell-shaped membership function with A, B and C parameters.

Description

Generalized bell-shaped membership function shape is similar to Gaussian functions. The function is smooth and takes non-zero values along the entire definition area.

A [sample code](#) for plotting a chart is displayed below.

Declaration

```
class CGeneralizedBellShapedMembershipFuncion : public IMembershipFunction
```

Title

```
#include <Math\Fuzzy\membershipfunction.mqh>
```

```

```
//--- sets the Y-axis properties
graphic.YAxis().AutoScale(false);
graphic.YAxis().Min(0.0);
graphic.YAxis().Max(1.1);
graphic.YAxis().DefaultStep(0.2);
//--- plot
graphic.CurvePlotAll();
graphic.Update();
}
```

A (Get method)

Gets the membership function concentration ratio.

```
double A()
```

Return Value

Concentration ratio value.

A (Set method)

Sets the membership function concentration ratio.

```
void A(
    const double a    // concentration ratio value
)
```

Parameters

a

[in] Membership function concentration ratio.

B (Get method)

Gets the membership function slope ratio.

```
double B()
```

Return Value

Slope ratio value.

B (Set method)

Sets the membership function slope ratio.

```
void B(
    const double b    // slope ratio value
)
```

```
)
```

Parameters

b

[in] Membership function slope ratio.

C (Get method)

Gets the membership function maximum coordinate.

```
double C()
```

Return Value

Membership function maximum coordinate.

C (Set method)

Sets the membership function maximum coordinate.

```
void C(  
    const double c    // maximum coordinate value  
)
```

Parameters

c

[in] Membership function maximum coordinate.

GetValue

Calculates the value of the membership function by a specified argument.

```
double GetValue(  
    const x    // membership function argument  
)
```

Parameters

x

[in] Membership function argument.

Return Value

Membership function value.

CNormalCombinationMembershipFunction

Class for implementing a two-sided Gaussian membership function with the B1, B2, Sigma1 and Sigma2 parameters.

Description

The two-sided Gaussian membership function is formed using Gaussian distribution. It allows setting asymmetrical membership functions. The function is smooth and takes non-zero values along the entire definition area.

A [sample code](#) for plotting a chart is displayed below.

Declaration

```
class CNormalCombinationMembershipFunction : public IMembershipFunction
```

Title

```
#include <Math\Fuzzy\membershipfunction.mqh>
```

Inheritance hierarchy

graphic.Update();
}
```

B1 (Get method)

Gets the value of the first membership function center.

```
double B1()
```

Return Value

Value of the first membership function center.

B1 (Set method)

Sets the value of the first membership function center.

```
void B1(
    const double b1    // first center value
)
```

Parameters

b

[in] Value of the first membership function center.

B2 (Get method)

Gets the value of the second membership function center.

```
double B2()
```

Return Value

The value of the second membership function center.

B2 (Set method)

Sets the value of the second membership function center.

```
void B2(  
    const double b2      // second center value  
)
```

Parameters

b2

[in] Value of the second membership function center.

Sigma1 (Get method)

Gets the first parameter of the membership function curvature.

```
double Sigma1()
```

Return Value

The value of the first parameter of the membership function curvature.

Sigma1 (Set method)

Sets the value of the first parameter of the membership function curvature.

```
void Sigma1(  
    const double sigma1  // first curvature parameter value  
)
```

Parameters

sigma1

[in] The first parameter of the membership function curvature.

Sigma2 (Get method)

Gets the second parameter of the membership function curvature.

```
double Sigma2()
```

Return Value

The value of the second parameter of the membership function curvature.

Sigma2 (Set method)

Sets the value of the second parameter of the membership function curvature.

```
void Sigma2(  

```

```
const double sigma2 // second curvature parameter value
)
```

Parameters

sigma2

[in] The second curvature parameter of the membership function.

GetValue

Calculates the value of the membership function by a specified argument.

```
double GetValue (
    const x // membership function argument
)
```

Parameters

x

[in] Membership function argument.

Return Value

Membership function value.

CNormalMembershipFunction

Class for implementing a symmetrical Gaussian membership function with the B and Sigma parameters.

Description

The symmetrical Gaussian membership function is formed using Gaussian distribution. The function is smooth and takes non-zero values along the entire definition area.

A [sample code](#) for plotting a chart is displayed below.

Declaration

```
class CNormalMembershipFunction : public IMembershipFunction
```

Title

```

//--- sets the Y-axis properties
graphic.YAxis().AutoScale(false);
```

```
graphic.YAxis().Min(0.0);  
graphic.YAxis().Max(1.1);  
graphic.YAxis().DefaultStep(0.2);  
/-- plot  
graphic.CurvePlotAll();  
graphic.Update();  
}
```

B (Get method)

Gets the membership function center.

```
double B()
```

Return Value

The value of the membership function center.

B (Set method)

Sets the value of the membership function center.

```
void B(  
    const double b    // function center value  
)
```

Parameters

b

[in] Value of the membership function center.

Sigma (Get method)

Gets the parameter of the membership function curvature.

```
double Sigma()
```

Return Value

The value of the membership function curvature parameter.

Sigma (Set method)

Sets the value of the membership function curvature parameter.

```
void Sigma(  
    const double sigma    // curvature parameter value  
)
```

Parameters

sigma

[in] Membership function curvature parameter.

GetValue

Calculates the value of the membership function by a specified argument.

```
double GetValue(  
    const double x    // argument  
)
```

Parameters

x

[in] Membership function argument.

Return Value

Membership function value.

CP_ShapedMembershipFunction

Class for implementing a pi-shaped membership function with the A, B, C and D parameters.

Description

The pi-shaped membership function has the form of a curvilinear trapezoid. The function is used to set asymmetric membership functions with a smooth transition from pessimistic to optimistic fuzzy number assessment.

A [sample code](#) for plotting a chart is displayed below.

Declaration

```
class CP_ShapedMembershipFunction : public IMembershipFunction
```

Title

```
#include <Math\Fuzzy\membershipfunction.mqh>
```

Inheritance hierarchy

- [CObject](#)
 - [IMembershipFunction](#)

}
```

A (Get method)

Gets the parameter of the fuzzy set beginning.

```
double A()
```

Return Value

Parameter of the fuzzy set beginning.

A (Set method)

Sets the parameter of the fuzzy set beginning.

```
void A(
    const double a    // parameter of the fuzzy set beginning
)
```

Parameters

a

[in] Parameter of the fuzzy set beginning.

B (Get method)

Gets the first parameter of the fuzzy set core.

```
double B()
```

Return Value

The first parameter of the fuzzy set core.

B (Set method)

Sets the first parameter of the fuzzy set core.

```
void B(
    const double b    // value of the fuzzy set core first parameter
)
```

Parameters

b

[in] The first parameter of the fuzzy set core.

C (Get method)

Gets the second parameter of the fuzzy set core.

```
double C()
```

Return Value

The second parameter of the fuzzy set core.

C (Set method)

Sets the second parameter of the fuzzy set core.

```
void C(  
    const double c    // value of the fuzzy set core second parameter  
)
```

Parameters

c

[in] The second parameter of the fuzzy set core.

D (Get method)

Gets the parameter of the fuzzy set end.

```
double D()
```

Return Value

Value of the fuzzy set end parameter.

D (Set method)

Sets the parameter of the fuzzy set end.

```
void D(  
    const double d    // value of the fuzzy set end parameter  
)
```

Parameters

d

[in] Value of the fuzzy set end parameter.

GetValue

Calculates the value of the membership function by a specified argument.

```
double GetValue(  
    const double x  
)
```

Parameters

x

[in] membership function argument

Return Value

membership function value

CProductTwoSigmoidalMembershipFunction

Class for implementing the membership function in the form of a product of two sigmoid functions with the A1, A2, C1 and C2 parameters.

Description

A product of two sigmoid membership functions is applied for setting smooth asymmetric functions. It allows creating membership functions with the values equal to 1 beginning with an argument value. Such functions are suitable if you need to set such linguistic terms as "short" or "long".

A [sample code](#) for plotting a chart is displayed below.

Declaration

```
class CProductTwoSigmoidalMembershipFunction : public IMembershipFunction
```

Title

```
#include <Math\Fuzzy\membershipfunction.mqh>
```

Inheritance hierarchy

[CObject](#)
[IMembershipFunction](#)

graphic.YAxis().Max(1.1);
graphic.YAxis().DefaultStep(0.2);
//--- plot
graphic.CurvePlotAll();
graphic.Update();
}
```

A1 (Get method)

Gets the first membership function slope ratio.

```
double A1()
```

Return Value

The first membership function slope ratio.

A1 (Set method)

Sets the first membership function slope ratio.

```
void A1(
    const double a1    // the first membership function slope ratio
)
```

Parameters

a1

[in] The first membership function slope ratio.

A2 (Get method)

Gets the second membership function slope ratio.

```
double A2()
```

Return Value

The second membership function slope ratio.

A2 (Set method)

Sets the second membership function slope ratio.

```
void A2(  
    const double a2      // the second membership function slope ratio  
)
```

Parameters

a2

[in] The second membership function slope ratio.

C1 (Get method)

Gets the first membership function inflection coordinate parameter.

```
double C1()
```

Return Value

The first membership function inflection coordinate.

C1 (Set method)

Sets the first membership function inflection coordinate.

```
void C1(  
    const double c1      // the first membership function inflection coordinate  
)
```

Parameters

c1

[in] The first membership function inflection coordinate.

C2 (Get method)

Gets the second membership function inflection coordinate parameter.

```
double C2()
```

Return Value

The second membership function inflection coordinate.

C2 (Set method)

Sets the second membership function inflection coordinate.

```
void C2(  
    const double c2      // the second membership function inflection coordinate  
)
```

Parameters

c2

[in] The second membership function inflection coordinate.

GetValue

Calculates the value of the membership function by a specified argument.

```
double GetValue (
    const x      // membership function argument
)
```

Parameters

x

[in] Membership function argument.

Return Value

Membership function value.

CS_ShapedMembershipFunction

Class for implementing an S-like membership function with the A and B parameters.

Description

The function sets an S-like two-parameter membership function. This is a non-decreasing function that takes values from 0 to 1. The A and B parameters define the interval, within which the function increases in non-linear trajectory from 0 to 1.

The function represents fuzzy sets of "very high" type (i.e. non-decreasing membership functions with saturation are set).

A [sample code](#) for plotting a chart is displayed below.

Declaration

```
class CS_ShapedMembershipFunction : public IMembershipFunction
```

Title

```
#include <Math\Fuzzy\membershipfunction.mqh>
```

Inheritance hierarchy

- [CObject](#)
- [IMembershipFunction](#)
- CS_ShapedMembershipFunction

Class methods

Class method	Description
A	Gets and sets the parameter of the increasing interval start.

<u>B</u>	Gets and sets the first parameter of the fuzzy set core.
<u>GetValue</u>	Calculates the value of the membership function by a specified argument.

Methods inherited from class CObject

Prev, Prev, Next, Next, [Save](#), [Load](#), [Type](#), [Compare](#)

Example

```

graphic.YAxis().Min(0.0);
graphic.YAxis().Max(1.1);
graphic.YAxis().DefaultStep(0.2);
//--- plot
graphic.CurvePlotAll();
graphic.Update();
}
```

A (Get method)

Gets the parameter of the increasing interval start.

```
double A()
```

Return Value

Increasing interval start parameter.

A (Set method)

Sets the parameter of the increasing interval start.

```
void A(
    const double a    // increasing interval start parameter
)
```

Parameters

a

[in] Increasing interval start parameter.

B (Get method)

Gets the first parameter of the fuzzy set core.

```
double B()
```

Return Value

The first parameter of the fuzzy set core.

B (Set method)

Sets the first parameter of the fuzzy set core.

```
void B(
    const double b    // the first parameter of the fuzzy set core
)
```

Parameters

b

[in] The first parameter of the fuzzy set core.

GetValue

Calculates the value of the membership function by a specified argument.

```
double GetValue (
    const x      // membership function argument
)
```

Parameters

x

[in] Membership function argument.

Return Value

Membership function value.

CSigmoidalMembershipFunction

Class for implementing a sigmoid membership function with the A and C parameters.

Description

The sigmoid function is applied when setting monotonous membership functions. It allows creating membership functions with the values equal to 1 beginning with an argument value. Such functions are suitable if you need to set such linguistic terms as "short" or "long".

A [sample code](#) for plotting a chart is displayed below.

Declaration

```
class CSigmoidalMembershipFuncion : public IMembershipFunction
```

Title

```
#include <Math\Fuzzy\membershipfunction.mqh>
```

Inheritance hierarchy

- [CObject](#)
- [IMembershipFunction](#)
- CSigmoidalMembershipFunction

Class methods

Class method	Description
A	Gets and sets the membership function slope ratio.
C	Gets and sets the membership function inflection coordinate parameter.

}
```

A (Get method)

Gets the membership function slope ratio.

```
double A()
```

Return Value

The membership function slope ratio.

A (Set method)

Sets the membership function slope ratio.

```
void A(  
    const double a    // the first membership function slope ratio  
)
```

Parameters

a

[in] Membership function slope ratio.

C (Get method)

Gets the membership function inflection coordinate parameter.

```
double C()
```

Return Value

Membership function inflection coordinate.

C (Set method)

Sets the membership function inflection coordinate.

```
void C(  
    const double c    // membership function inflection coordinate  
)
```

Parameters

c

[in] The membership function inflection coordinate.

GetValue

Calculates the value of the membership function by a specified argument.

```
double GetValue(  
    const x      // membership function argument  
)
```

Parameters

x

[in] Membership function argument.

Return Value

Membership function value.

CTrapezoidMembershipFunction

Class for implementing a trapezoidal membership function with the X1, X2, X3 and X4 parameters.

Description

The function is formed using piecewise linear approximation. This is a generalization of the triangular function allowing you to assign a fuzzy set core as an interval. Such a membership function makes it possible to conveniently interpret optimistic/pessimistic assessments.

The function is used to set asymmetric membership functions of the variables with their most critical values defined within a certain interval.

A [sample code](#) for plotting a chart is displayed below.

Declaration

```
class CTrapezoidMembershipFunction : public IMembershipFunction
```

Title

```
#include <Math\Fuzzy\membershipfunction.mqh>
```

Inheritance hierarchy

[CObject](#)
[IMembershipFunction](#)
CTrapezoidMembershipFunction

Class methods

Class method	Description
X1	Gets and sets the value of the first point on the X axis.

X2	Gets and sets the value of the second point on the X axis.
X3	Gets and sets the value of the third point on the X axis.
X4	Gets and sets the value of the fourth point on the X axis.
GetValue	Calculates the value of the membership function by a specified argument.

graphic.Update();
}
```

X1 (Get method)

Gets the value of the first point on the X axis.

```
double X1()
```

Return Value

The value of the first point on the X axis.

X1 (Set method)

Sets the value of the first point on the X axis.

```
void X1(
    const double x1    // value of the first point on the X axis
)
```

Parameters

x1

[in] The value of the first point on the X axis.

X2 (Get method)

Gets the value of the second point on the X axis.

```
double X2()
```

Return Value

The value of the second point on the X axis.

X2 (Set method)

Sets the value of the second point on the X axis.

```
void X2(
```

```
const double x2      // value of the second point on the X axis
)
```

Parameters

x2

[in] The value of the second point on the X axis.

X3 (Get method)

Gets the value of the third point on the X axis.

```
double X3()
```

Return Value

The value of the third point on the X axis.

X3 (Set method)

Sets the value of the third point on the X axis.

```
void X3(
    const double x3      // value of the third point on the X axis
)
```

Parameters

x3

[in] The value of the third point on the X axis.

X4 (Get method)

Gets the value of the fourth point on the X axis.

```
double X4()
```

Return Value

The value of the fourth point on the X axis.

X4 (Set method)

Sets the value of the fourth point on the X axis.

```
void X4(
    const double x4      // value of the fourth point on the X axis
)
```

Parameters

x4

[in] The value of the fourth point on the X axis.

GetValue

Calculates the value of the membership function by a specified argument.

```
double GetValue(  
    const x      // membership function argument  
)
```

Parameters

x

[in] Membership function argument.

Return Value

Membership function value.

CTriangularMembershipFunction

Class for implementing a triangle membership function with the X1, X2 and X3 parameters.

Description

The function sets a membership function in the form of a triangle. This is a simple and most frequently applied membership function.

A [sample code](#) for plotting a chart is displayed below.

Declaration

```
class CTriangularMembershipFunction : public IMembershipFunction
```

Title

```
#include <Math\Fuzzy\membershipfunction.mqh>
```

Inheritance hierarchy

CObject

}
```

X1 (Get method)

Gets the value of the first point on the X axis.

```
double X1()
```

Return Value

The value of the first point on the X axis.

X1 (Set method)

Sets the value of the first point on the X axis.

```
void X1(  
    const double x1    // value of the first point on the X axis  
)
```

Parameters

x1

[in] The value of the first point on the X axis.

X2 (Get method)

Gets the value of the second point on the X axis.

```
double X2()
```

Return Value

The value of the second point on the X axis.

X2 (Set method)

Sets the value of the second point on the X axis.

```
void X2(  
    const double x2    // value of the second point on the X axis  
)
```

Parameters

x2

[in] The value of the second point on the X axis.

X3 (Get method)

Gets the value of the third point on the X axis.

```
double X3 ()
```

Return Value

The value of the third point on the X axis.

X3 (Set method)

Sets the value of the third point on the X axis.

```
void X3 (
    const double x3      // value of the third point on the X axis
)
```

Parameters

x3

[in] The value of the third point on the X axis.

ToNormalMF

Converts a triangle membership function into a Gaussian one.

```
CNormalMembershipFunction* ToNormalMF ()
```

Return Value

The pointer to a [Gaussian membership function](#).

GetValue

Calculates the value of the membership function by a specified argument.

```
double GetValue (
    const x      // membership function argument
)
```

Parameters

x

[in] Membership function argument.

Return Value

Membership function value.

CZ_ShapedMembershipFunction

Class for implementing a z-like membership function with the A and B parameters.

Description

The function sets a z-like two-parameter membership function. This is a non-increasing membership function that takes values from 1 to 0. The function parameters define an interval, within which the function decreases in non-linear trajectory from 1 to 0.

The function represents fuzzy sets of "very low" type. In other words, it sets non-increasing membership functions with saturation.

A [sample code](#) for plotting a chart is displayed below.

Declaration

```
class CZ_ShapedMembershipFunction : public IMembershipFunction
```

Title

```
#include <Math\Fuzzy\membershipfunction.mqh>
```

Inheritance hierarchy

graphic.Update();
}
```

A (Get method)

Gets the parameter of the decreasing interval start.

```
double A()
```

Return Value

Decreasing interval start parameter.

A (Set method)

Sets the parameter of the decreasing interval start.

```
void A(
    const double a    // decreasing interval start parameter
)
```

Parameters

a

[in] Decreasing interval start parameter.

B (Get method)

Gets the parameter of the decreasing interval end.

```
double B()
```

Return Value

Decreasing interval end parameter.

B (Set method)

Sets the parameter of the decreasing interval end.

```
void B(
    const double b    // decreasing interval end parameter
)
```

Parameters

b

[in] Decreasing interval end parameter.

GetValue

Calculates the value of the membership function by a specified argument.

```
double GetValue (  
    const x      // membership function argument  
)
```

Parameters

x

[in] Membership function argument.

Return Value

Membership function value.

IMembershipFunction

```

Parameters

x
[in] Membership function argument.

Return Value

Membership function value.

Fuzzy systems rules

A **fuzzy system** (fuzzy logical inference system) is a receipt of conclusion in the form of a fuzzy set corresponding to the current values of the inputs with the use of a set of **fuzzy rules** and fuzzy operations.

The **fuzzy rules** determine the relationship between inputs and outputs of an examined object. Amount of rules in the system is unlimited. The generalized format of fuzzy rules is as follows:

if rule condition, then rule conclusion.

Rule condition describes the current state of the object. *Rule conclusion* describes how the condition affects the object.

Class of rules for fuzzy systems	Description
<u>CMamdaniFuzzyRule</u>	Class for implementing a fuzzy logic rule for the Mamdani algorithm
<u>CSugenoFuzzyRule</u>	Class for implementing a fuzzy logic rule for the Sugeno algorithm
<u>CSingleCondition</u>	The class sets a fuzzy condition expressed by "Fuzzy variable – Fuzzy term" pair.
<u>CConditions</u>	Class defines a set of fuzzy conditions connected to each other by an operator.
<u>CGenericFuzzyRule</u>	Base class for implementing the both types of fuzzy rules.

CMamdaniFuzzyRule

Mamdani-type fuzzy inference – one of the two basic types of fuzzy systems. Output variable values are set using fuzzy terms.

Description

Fuzzy logic rule for the Mamdani algorithm can be described as follows:

$$if(X_1 \text{ is } a_1) \wedge (X_2 \text{ is } a_2) \wedge \dots \wedge (X_n \text{ is } a_n) \text{ then } (Y \text{ is } d)(W)$$

where:

- X = (X1, X2, X3 ... Xn) – vector of input variables;
- Y – output variable;
- a = (a1, a2, a3 ... an) – vector of input variable values;
- d – output variable value;
- W – rule weight.

Declaration

```
class CMamdaniFuzzyRule : public CGenericFuzzyRule
```

Title

```
#include <Math\Fuzzy\fuzzyrule.mqh>
```

Inheritance hierarchy

Class methods

Class method	Description
Conclusion	Gets and sets the Mamdani fuzzy rule conclusion
Weight	Gets and sets the Mamdani fuzzy rule weight

[Condition](#), [Condition](#), [CreateCondition](#), [CreateCondition](#), [CreateCondition](#)

Conclusion (Get method)

Gets the Mamdani fuzzy rule conclusion

```
CSingleConditon* Conclusion()
```

Return Value

Conclusion of a Mamdani fuzzy rule.

Conclusion (Set method)

Sets the Mamdani fuzzy rule conclusion.

```
void Conclusion(  
    CSingleConditon* value    // conclusion of a Mamdani fuzzy rule  
)
```

Parameters

value

[in] Conclusion of a Mamdani fuzzy rule.

Weight (Get method)

Gets the Mamdani fuzzy rule weight.

```
double Weight()
```

Return Value

Mamdani fuzzy rule weight.

Weight (Set method)

Sets the Mamdani fuzzy rule weight.

```
void Weight(  
    const double value    // weight of a Mamdani fuzzy rule  
)
```

Parameters

value

[in] Weight of a Mamdani fuzzy rule.

CSugenoFuzzyRule

Sugeno-type fuzzy inference – one of the two basic types of fuzzy systems. Output variable values are set as a linear combination of input variables.

Description

Unlike the Mamdani rule, an input variable value is set by a linear function from entries rather than by a fuzzy term. Fuzzy logic rule for the Sugeno algorithm can be described as follows:

$$if(X_1 \text{ is } a_1) \wedge (X_2 \text{ is } a_2) \wedge \dots \wedge (X_n \text{ is } a_n) \text{ then } (Y = b_0 + b_1 \cdot X_1 + b_2 \cdot X_2 + \dots + b_n \cdot X_n)(W)$$

where:

- X = (X1, X2, X3 ... Xn) – vector of input variables;
- Y – output variable;
- a = (a1, a2, a3 ... an) – vector of input variable values;
- b = (b1, b2, b3 ... bn) – free term ratio in the linear function for an output value
- W – rule weight.

Declaration

```
class CSugenoFuzzyRule : public CGenericFuzzyRule
```

Title

```
#include <Math\Fuzzy\fuzzyrule.mqh>
```

Conclusion (Get method)

Gets the Sugeno fuzzy rule conclusion.

```
CSingleConditon* Conclusion()
```

Return Value

Sugeno fuzzy rule conclusion.

Conclusion (Set method)

Sets the Sugeno fuzzy rule conclusion.

```
void Conclusion(  
    CSingleCondition* value    // conclusion of a Sugeno fuzzy rule  
)
```

Parameters

value

[in] Conclusion of a Sugeno fuzzy rule.

CSingleCondition

The class sets a fuzzy condition expressed by "Fuzzy variable – Fuzzy term" pair.

Description

According to a fuzzy condition, one variable corresponds to one term. A fuzzy condition can be described by the following expression: X is a ,

where:

- X is a fuzzy variable;
- a is a fuzzy variable value (fuzzy term).

Declaration

```
class CSingleCondition : public ICondition
```

Title

```

Class methods

Class method	Description
Not	Gets and sets the flag indicating whether it is necessary to apply negation to this condition.
Term	Gets and sets a fuzzy term for this condition.
Var	Gets and sets a fuzzy variable for this condition.

Methods inherited from class CObject

Prev, Prev, Next, Next, [Save](#), [Load](#), [Type](#), [Compare](#)

Not (Get method)

Gets the flag indicating whether it is necessary to apply negation to this condition.

```
bool Not()
```

Return Value

The flag value.

Not (Set method)

Sets the flag indicating whether it is necessary to apply negation to this condition.

```
void Not(  
    bool not      // flag value  
)
```

Parameters

not

[in] Flag value.

Term (Get method)

Gets a fuzzy term for the given condition.

```
INamedValue* Term()
```

Return Value

A fuzzy term for the given condition.

Term (Set method)

Sets a fuzzy term for the given condition.

```
void Term(  
    INamedValue*& value      // fuzzy term for the given condition  
)
```

Parameters

value

[in] A fuzzy term for the given condition.

Var (Get method)

Gets a fuzzy variable for the given condition.

```
INamedVariable* Var()
```

Return Value

A fuzzy variable for the given condition.

Var (Set method)

Sets a fuzzy variable for the given condition

```
void Var(  
    INamedVariable*& value    // a fuzzy variable for the given condition  
)
```

Parameters

value

[in] fuzzy variable.

CConditions

Class defines a set of fuzzy conditions connected to each other by an operator.

Description

A set of fuzzy conditions connected to each other by an operator may be described as follows:

$$(X_1 \text{ is } a_1) \wedge (X_2 \text{ is } a_2) \wedge \dots \wedge (X_n \text{ is } a_n)$$

where:

- $X = (X_1, X_2, X_3 \dots X_n)$ – vector of input variables;
- $a = (a_1, a_2, a_3 \dots a_n)$ – vector of input variable values.

In this example, the *and* operator is used. Besides, the *or* operator is available in this class.

Declaration

```
class CConditions : public ICondition
```

Title

```
#include <Math\Fuzzy\fuzzyrule.mqh>
```

CConditions

Class methods

Class method	Description
<u>ConditionsList</u>	Gets the list of all conditions
<u>Not</u>	Gets and sets the flag indicating whether it is necessary to apply negation to these conditions
<u>Op</u>	Gets and sets a type of the conditions bundle operator.

Methods inherited from class CObject

Prev, Prev, Next, Next, [Save](#), [Load](#), [Type](#), [Compare](#)

ConditionsList

Gets the list of all conditions.

```
CList* ConditionsList()
```

Return Value

List of all conditions.

Not (Get method)

Gets the flag indicating whether it is necessary to apply negation to these conditions.

```
bool Not()
```

Return Value

The flag value.

Not (Set method)

Sets the flag indicating whether it is necessary to apply negation to these conditions

```
void Not(  
    bool not    // flag value  
)
```

Parameters

not

[in] Flag value.

Op (Get method)

Gets a type of the conditions bundle operator. The *and* and *or* operators are available.

```
OperatorType Op()
```

Return Value

Type of the conditions bundle operator.

Op (Set method)

Set the conditions bundle operator. The *and* and *or* operators are available.

```
void Op(  
    OperatorType op    // type of the conditions bundle operator  
)
```

Parameters

op

[in] Type of the conditions bundle operator.

CGenericFuzzyRule

Base class for both types of fuzzy rules.

Declaration

```
class CGenericFuzzyRule : public IParsableRule
```

Title

```
#include <Math\Fuzzy\fuzzyrule.mqh>
```

Inheritance hierarchy

CObject

CMamdaniFuzzyRule, CSugenoFuzzyRule

Class methods

Class method	Description
<u>Conclusion</u>	Gets and sets the fuzzy rule conclusion
<u>Condition</u>	Gets and sets the 'if' condition (set of conditions) for a fuzzy rule
<u>CreateCondition</u>	Creates a condition for a fuzzy rule by specified parameters

Methods inherited from class CObject

Prev, Prev, Next, Next, [Save](#), [Load](#), [Type](#), [Compare](#)

Conclusion (Get method)

Gets the conclusion of a fuzzy rule.

```
CSingleConditon* Conclusion()
```

Return Value

Conclusion of a fuzzy rule.

Conclusion (Set method)

Sets the fuzzy rule conclusion.

```
virtual void Conclusion(
    CSingleConditon* value    // conclusion of a fuzzy rule
```

```
)
```

Parameters*value*

[in] Conclusion of a fuzzy rule.

Condition (Get method)

Gets the 'if' condition (set of conditions) for a fuzzy rule.

```
CConditons* Condition()
```

Return Value

Fuzzy condition (set of conditions).

Condition (Set method)

Sets the 'if' condition (set of conditions) for a fuzzy rule.

```
void Condition(
    CConditons* value    // 'if' condition (set of conditions) for a fuzzy rule
)
```

Parameters*value*

[in] Fuzzy condition (set of conditions).

CreateCondition

Creates a condition for a fuzzy rule by specified parameters.

```
CFuzzyCondition* CreateCondition(
    CFuzzyVariable* var,    // fuzzy variable
    CFuzzyTerm* term,      // fuzzy term
)
```

Parameters*var*

[in] Fuzzy variable.

term

[in] Fuzzy term.

Return Value

Fuzzy rule status.

CreateCondition

Creates a condition for a fuzzy rule by specified parameters.

```
CFuzzyCondition* CreateCondition(
    CFuzzyVariable* var,      // fuzzy variable
    CFuzzyTerm* term,        // fuzzy term
    bool not,                // flag indicating whether it is necessary to apply negation
)
```

Parameters

var

[in] Fuzzy variable.

term

[in] Fuzzy term.

not

[in] Flag indicating whether it is necessary to apply negation to a condition.

Return Value

Fuzzy rule status.

CreateCondition

Creates a condition for a fuzzy rule by specified parameters.

```
CFuzzyCondition* CreateCondition(
    CFuzzyVariable* var,      // fuzzy variable
    CFuzzyTerm* term,        // fuzzy term
    bool not,                // flag indicating whether it is necessary to apply negation
    HedgeType hedge          // condition bundle type
)
```

Parameters

var

[in] Fuzzy variable.

term

[in] Fuzzy term.

not

[in] Flag indicating whether it is necessary to apply negation to a condition.

hedge

[in] Condition bundle type.

Return Value

Fuzzy rule status.

Fuzzy systems variables

Fuzzy (linguistic) variables **are applied in fuzzy systems**. These are the variables whose values are words or word combinations in a natural or artificial language.

Linguistic variables comprise fuzzy sets. The nature and number of fuzzy variables change for each certain task when defining fuzzy sets.

Class	Description
<u>CFuzzyVariable</u>	Class for creating general fuzzy variables.
<u>CSugenoVariable</u>	Class for creating fuzzy Sugeno-type variables.

CFuzzyVariable

Class for creating general fuzzy variables.

Description

Here, a fuzzy variable is created with the following parameters:

- maximum variable value;
- minimum variable value;
- fuzzy variable name;
- term set (set of all possible values, which a linguistic variable is capable of receiving).

Declaration

```
class CFuzzyVariable : public CNamedVariableImpl
```

Title

```
#include <Math\Fuzzy\fuzzyvariable.mqh>
```

<u>AddTerm</u>	Adds a single fuzzy term to a fuzzy variable.
<u>GetTermByName</u>	Gets a fuzzy term by a specified name.
<u>Max</u>	Gets and sets a maximum value for a fuzzy variable.
<u>Min</u>	Gets and sets a minimum value for a fuzzy variable.
<u>Terms</u>	Gets and sets a list of fuzzy terms for the given fuzzy variable.
<u>Values</u>	Gets and sets a list of fuzzy terms for the given fuzzy variable.

Methods inherited from class CObject

Prev, Prev, Next, Next, [Save](#), [Load](#), [Type](#), [Compare](#)

Methods inherited from class CNamedVariableImpl

Name, Name

AddTerm

Adds a single fuzzy term to a fuzzy variable.

```
void AddTerm(  
    CFuzzyTerm* & term    // fuzzy term  
)
```

Parameters

term

[in] Fuzzy term.

GetTermByName

Gets a fuzzy term by a specified name.

```
CFuzzyTerm* GetTermByName(  
    const string name    // fuzzy term name  
)
```

Parameters

name

[in] Fuzzy term name.

Return Value

Fuzzy term with a specified name.

Max (Get method)

Gets the maximum value for a fuzzy variable.

```
double Max()
```

Return Value

Maximum value for a fuzzy variable.

Max (Set method)

Sets the maximum value for a fuzzy variable.

```
void Max(  
    const double max    // maximum value for a fuzzy variable  
)
```

Parameters

max

[in] Maximum value for a fuzzy variable.

Min (Get method)

Gets the minimum value for a fuzzy variable.

```
double Min()
```

Return Value

Minimum value for a fuzzy variable.

Max (Set method)

Sets the minimum value for a fuzzy variable.

```
void Min(  
    const double min    // minimum value for a fuzzy variable  
)
```

Parameters

min

[in] Minimum value for a fuzzy variable.

Terms (Get method)

Gets a list of fuzzy terms for the given fuzzy variable.

```
CList* Terms()
```

Return Value

List of fuzzy terms for the given fuzzy variable.

Terms (Set method)

Sets a list of fuzzy terms for the given fuzzy variable.

```
void Terms(  
    CList*& terms    // list of fuzzy terms for the given variable  
)
```

Parameters

terms

[in] list of fuzzy terms for the given fuzzy variable.

Values

Gets a list of fuzzy terms for the given fuzzy variable.

```
CList* Values()
```

Return Value

List of fuzzy terms for the given variable.

CSugenoVariable

Class for creating fuzzy Sugeno-type variables.

Description

Fuzzy Sugeno-type variable is different from the general linguistic variable since it is not set by a term set but by a set of linear functions.

Declaration

```
class CSugenoVariable : public CNamedVariableImpl
```

Title

```
#include <Math\Fuzzy\sugenovvariable.mqh>

```

Return Value

List of linear functions.

GetFuncByName

Gets the linear function by a specified name.

```
ISugenoFunction* GetFuncByName (  
    const string name // linear function name  
)
```

Parameters

name

[in] Linear function name.

Return Value

Linear function with a specified name.

Values

Gets the list of linear functions of the fuzzy Sugeno variable.

```
CList* Values ()
```

Return Value

List of linear functions of the fuzzy Sugeno variable.

CFuzzyTerm (fuzzy terms)

Class for implementing fuzzy terms.

Description

A **term** is any element of a term set. A term is defined by two components:

- fuzzy term name;
- membership function.

Declaration

```
class CFuzzyTerm : public CNamedValueImpl
```

Title

```
#include <Math\Fuzzy\fuzzyterm.mqh>
```

Inheritance hierarchy

MembershipFunction

Gets a membership function for the fuzzy term.

```
IMembershipFunction* MembershipFunction()
```

Return Value

Membership function

Fuzzy systems

Fuzzy system (or *fuzzy model*) is a mathematical model whose calculation is based on fuzzy logic. Construction of such models is applicable when the subject of study has a weak formalization and its exact mathematical description is too complex or unknown.

The progress of a model construction can be divided into three main stages:

1. Definition of input and output characteristics of a model.
2. Building a knowledge base.
3. Selecting one of the methods of fuzzy inference (Mamdani and Sugeno).

The first stage directly effects the consequent two and determines the future operation of the model.

A **knowledge base** (*rule base*) is a set of fuzzy rules of "if, then" type that define the relationship between inputs and outputs of the examined object.

Rule condition describes the current state of the object, and **rule conclusion** — how this condition affects the object.

There can be two types of terms and conclusions for each rule:

1. simple (link to [Csinglecond](#)) — includes one fuzzy variable;
2. complex (link to [Cconditions](#)) — includes several fuzzy variables.

Each rule in the system has its **weight** — importance of a rule in the model. Weighting factors are assigned to a rule within range [0, 1].

Depending on the created knowledge base, the system of fuzzy inference is determined for a model.

Fuzzy logical inference is a receipt of conclusion in form of a fuzzy set corresponding to the current value of the inputs with use of knowledge base and fuzzy operations. The two main types of fuzzy inference are Mamdani and Sugeno.

Mamdani system

Output variable values in the Mamdani system are set using fuzzy terms.

Description

Fuzzy logic rule for the Mamdani algorithm can be described as follows:

$$if(X_1 \text{ is } a_1) \wedge (X_2 \text{ is } a_2) \wedge \dots \wedge (X_n \text{ is } a_n) \text{ then } (Y \text{ is } d)(W)$$

where:

- $X = (X_1, X_2, X_3 \dots X_n)$ – vector of input variables;
- Y – output variable;
- $a = (a_1, a_2, a_3 \dots a_n)$ – vector of input variable values;
- d – output variable value;
- W – rule weight.

Class methods

Class method	Description
AggregationMethod	Sets the type of conditions aggregation
Calculate	Calculates a fuzzy inference for the system
DefuzzificationMethod	Sets defuzzification method type
EmptyRule	Creates an empty fuzzy Mamdani rule based on the current system
ImplicationMethod	Sets a type of the system implication operator
Output	Gets the list of fuzzy Mamdani output variables.
OutputByName	Gets a fuzzy Mamdani output variable by a specified name.
ParseRule	Creates a fuzzy Mamdani rule based on a specified line.
Rules	Returns the list of fuzzy Mamdani rules.

Methods inherited from class CGenericFuzzySystem

Input, AndMethod, AndMethod, OrMethod, OrMethod, InputByName, Fuzzify

AggregationMethod

Sets the type of conditions aggregation method.

```
void AggregationMethod(
    AggregationMethod value    // aggregation method type
```

```
)
```

Parameters

value

[in] Type of conditions aggregation method.

Calculate

Calculates a fuzzy inference for the system

```
CList* Calculate(  
    CList* inputValues    // input data  
)
```

Parameters

inputValues

[in] Input data for calculation.

Return Value

Calculation result.

DefuzzificationMethod

Sets defuzzification method type.

```
void DefuzzificationMethod(  
    DefuzzificationMethod value    // defuzzification method type.  
)
```

Parameters

value

[in] Defuzzification method type.

EmptyRule

Creates an empty fuzzy Mamdani rule based on the current system

```
CMamdaniFuzzyRule* EmptyRule()
```

Return Value

Fuzzy Mamdani rule.

ImplicationMethod

Sets a type of the conditions implication operator.

```
void ImplicationMethod(  
    ImplicationMethod value    // implication operator type
```

```
)
```

Parameters

value

[in] Type of the conditions implication operator.

Output

Gets the list of fuzzy Mamdani output variables.

```
CList* Output()
```

Return Value

List of fuzzy variables.

OutputByName

Gets a fuzzy Mamdani output variable by a specified name.

```
CFuzzyVariable* OutputByName(  
    const string name    // fuzzy variable name  
)
```

Parameters

name

[in] Fuzzy variable name.

Return Value

Fuzzy Mamdani variable with a specified name.

ParseRule

Creates a fuzzy Mamdani rule based on a specified line.

```
CMamdaniFuzzyRule* ParseRule(  
    const string rule    // string representation of a fuzzy rule  
)
```

Parameters

rule

[in] String representation of a fuzzy Mamdani rule.

Return Value

Fuzzy Mamdani rule.

Rules

Returns the list of fuzzy Mamdani rules.

```
CList* Rules ()
```

Return Value

List of fuzzy Mamdani rules.

Sugeno system

Sugeno fuzzy logic system is one of the two basic types of fuzzy systems. Output variable values are set as a linear combination of input variables.

Description

Unlike the Mamdani rule, an input variable value is set by a linear function from entries rather than by a fuzzy term. Fuzzy logic rule for the Sugeno algorithm can be described as follows:

if $(X_1 \text{ is } a_1) \wedge (X_2 \text{ is } a_2) \wedge \dots \wedge (X_n \text{ is } a_n)$ *then* $(Y = b_0 + b_1 \cdot X_1 + b_2 \cdot X_2 + \dots + b_n \cdot X_n)(W)$

where:

- $X = (X_1, X_2, X_3 \dots X_n)$ – vector of input variables;
- Y – output variable;
- $a = (a_1, a_2, a_3 \dots a_n)$ – vector of input variable values;
- $b = (b_1, b_2, b_3 \dots b_n)$ – free term ratio in the linear function for an output value
- W – rule weight.

Class methods

Class method	Description
Calculate	Calculates a fuzzy inference for the system
CreateSugenoFunction	Creates a linear Sugeno function for the system.
EmptyRule	Creates an empty fuzzy Sugeno rule based on the current system.
Output	Gets the list of fuzzy Sugeno output variables.
OutputByName	Gets a fuzzy Sugeno output variable by a specified name.
ParseRule	Creates a fuzzy Sugeno rule based on a specified line.
Rules	Returns the list of fuzzy rules.

Methods inherited from class CGenericFuzzySystem

Input, AndMethod, AndMethod, OrMethod, OrMethod, InputByName, Fuzzify

Calculate

Calculates a fuzzy inference for the system

```
CList* Calculate(
    CList*& inputValues    // input data
)
```

Parameters*inputValues*

[in] Input data for calculation.

Return Value

Calculation result.

CreateSugenoFunction

Creates a linear Sugeno function for the system.

```

CLinearSugenoFunction* CreateSugenoFunction (
    const string  name,           // function name
    const double& coeffs[]        // function ratios
)

```

Parameters*name*

[in] Function name.

coeffs[]

[in] Function ratios.

Return Value

Linear Sugeno function.

Note

The size of the ratio array may be equal to a number of inputs or exceed that number by one. In the first case, the free term of the Sugeno linear function is equal to zero, while in the second case, it is equal to the last ratio.

CreateSugenoFunction

Creates a linear Sugeno function for the system.

```

CLinearSugenoFunction* CreateSugenoFunction (
    const string  name,           // function name
    CList*&       coeffs,         // list of pairs fuzzy variable - its ratio
    const double  constValue      // function free term ratio
)

```

Parameters*name*

[in] Function name.

coeffs[]

[in] Function ratios.

Return Value

Linear Sugeno function.

EmptyRule

Creates an empty fuzzy Sugeno rule based on the current system.

```
CSugenoFuzzyRule* EmptyRule()
```

Return Value

Fuzzy Sugeno rule.

Output

Gets the list of fuzzy Sugeno output variables.

```
CList* Output()
```

Return Value

List of fuzzy variables.

OutputByName

Gets a fuzzy Sugeno output variable by a specified name.

```
CSugenoVariable* OutputByName(  
    const string name    // fuzzy variable name  
)
```

Parameters

name

Fuzzy variable name.

Return Value

Fuzzy Sugeno variable with a specified name.

ParseRule

Creates a fuzzy Sugeno rule based on a specified line.

```
CSugenoFuzzyRule* ParseRule(  
    const string rule    // string representation of a fuzzy Sugeno rule  
)
```

Parameters

rule

[in] String representation of a fuzzy Sugeno rule.

Return Value

Fuzzy Sugeno rule.

Rules

Returns the list of fuzzy rules.

```
CList* Rules ()
```

Return Value

List of fuzzy rules.

Class for working with OpenCL programs

The COpenCL class is a wrapper to facilitate working with the [OpenCL functions](#). In some cases, use of the GPU allows to substantially increase the speed of computations.

Examples of class use for calculations based on float and double values can be found in the corresponding subdirectories of the MQL5\Scripts\Examples\OpenCL\ folder. The source codes of the OpenCL programs are located in MQL5\Scripts\Examples\OpenCL\Double\Kernels and MQL5\Scripts\Examples\OpenCL\Float\Kernels subdirectories.

- MatrixMult.mq5 - example of matrix multiplication using global and local memory
- BitonicSort.mq5 - example of parallel sorting of array elements in GPU
- FFT.mq5 - example of fast Fourier transform calculation
- Wavelet.mq5 - example of wavelet transform of data using the Morlet wavelet.

It is recommended to write the source code for OpenCL in separate CL files, which can later be included in the MQL5 program using the [resource variables](#).

Declaration

```
class COpenCL
```

Title

```
#include <OpenCL\OpenCL.mqh>
```

Class methods

Name	Description
BufferCreate	Creates an OpenCL buffer at the specified index
BufferFree	Deletes buffer at the specified index
BufferFromArray	Creates a buffer at the specified index from an array of values
BufferRead	Reads an OpenCL buffer at the specified index into an array
BufferWrite	Writes an array of values into buffer at the specified index
Execute	Executes the OpenCL kernel with the specified index
GetContext	Returns handle of the OpenCL context
GetKernel	Returns handle of the kernel object at the specified index
GetKernelName	Returns name of the kernel object at the specified index

<u>GetProgram</u>	Returns handle of the OpenCL program
<u>Initialize</u>	Initializes the OpenCL program
<u>KernelCreate</u>	Creates an entry point into the OpenCL program at the specified index
<u>KernelFree</u>	Removes an OpenCL start function at the specified index
<u>SetArgument</u>	Sets a parameter for the OpenCL function at the specified index
<u>SetArgumentBuffer</u>	Sets an OpenCL buffer as a parameter of the OpenCL function at the specified index
<u>SetArgumentLocalMemory</u>	Sets a parameter in local memory for the OpenCL function at the specified index
<u>SetBuffersCount</u>	Sets the number of buffers
<u>SetKernelsCount</u>	Sets the number of kernel objects
<u>Shutdown</u>	Unloads the OpenCL program
<u>SupportDouble</u>	Checks if floating point data types are supported on the device

BufferCreate

Creates an OpenGL buffer at the specified index.

```
bool BufferCreate(  
    const int   buffer_index,      // buffer index  
    const uint  size_in_bytes,     // buffer size in bytes  
    const uint  flags              // combination of flags that define the buffer properties  
);
```

Parameters

buffer_index

[in] Index buffer.

size_in_bytes

[in] Buffer size in bytes.

flags

[in] Buffer properties that are set using a combination of flags.

Return Value

In case of successful execution, returns true, otherwise - false.

BufferFree

Deletes buffer at the specified index.

```
bool BufferFree(  
    const int  buffer_index    // buffer index  
);
```

Parameters

buffer_index
[in] Index buffer.

Return Value

In case of successful execution, returns true, otherwise - false.

BufferFromArray

Creates a buffer at the specified index from an array of values.

```
template<typename T>
bool BufferFromArray(
    const int    buffer_index,           // buffer index
    T            &data[],               // array of values
    const uint   data_array_offset,     // offset in the array of values, in bytes
    const uint   data_array_count,     // number of values from the array to write
    const uint   flags                  // combination of flags that define the buffer p
);
```

Parameters

buffer_index

[in] Index buffer.

&data[]

[in] An array of values to be written into the OpenCL buffer.

data_array_offset

[in] Offset in the array of values in bytes, from which writing of values begins.

data_array_count

[in] The number of values to be written.

flags

[in] Buffer properties that are set using a combination of flags.

Return Value

In case of successful execution, returns true, otherwise - false.

BufferRead

Reads an OpenCL buffer at the specified index into an array.

```
template<typename T>
bool BufferRead(
    const int    buffer_index,           // buffer index
    T            &data[],               // array of values
    const uint   cl_buffer_offset,      // offset in the OpenCL buffer, in bytes
    const uint   data_array_offset,     // shift in the array elements
    const uint   data_array_count       // number of values from the buffer to read
);
```

Parameters

buffer_index

[in] Index buffer.

&data[]

[in] Array to obtain the values of the OpenCL buffer.

cl_buffer_offset

[in] Offset in the OpenCL buffer in bytes, from which to start reading values.

data_array_offset

[in] Index of the first element of the array to write values of the OpenCL buffer.

data_array_count

[in] The number of values to be read.

Return Value

In case of successful execution, returns true, otherwise - false.

BufferWrite

Writes an array of values into buffer at the specified index.

```
template<typename T>
bool BufferWrite(
    const int    buffer_index,           // buffer index
    T            &data[],               // array of values
    const uint   cl_buffer_offset,      // offset in the OpenCL buffer, in bytes
    const uint   data_array_offset,     // shift in the array elements
    const uint   data_array_count       // number of values from the array to write
);
```

Parameters

buffer_index

[in] Index buffer.

&data[]

[in] An array of values to be written into the OpenCL buffer.

cl_buffer_offset

[in] Offset in the OpenCL buffer in bytes, from which to start writing values.

data_array_offset

[in] Index of the first element of the array, starting from which the array values are written to the OpenCL buffer.

data_array_count

[in] The number of values to be written.

Return Value

In case of successful execution, returns true, otherwise - false.

Execute

Executes the OpenCL program at the specified index.

```
bool Execute(  
    const int    kernel_index,           // index of the kernel  
    const int    work_dim,              // dimension of the tasks space  
    const uint   &work_offset[],        // initial offset in the tasks space  
    const uint   &work_size[]           // total number of tasks  
);
```

Executes the OpenCL kernel with the specified index and number of tasks in the local group.

```
bool Execute(  
    const int    kernel_index,           // index of the kernel  
    const int    work_dim,              // dimension of the tasks space  
    const uint   &work_offset[],        // initial offset in the tasks space  
    const uint   &work_size[],          // total number of tasks  
    const uint   &local_work_size[]     // number of tasks in the local group  
);
```

Parameters

kernel_index

[in] Index of the kernel object.

work_dim

[in] Dimension of the tasks space.

&work_offset[]

[in][out] Initial offset in the tasks space. Passed by reference.

&work_size[]

[in][out] The size of the tasks subset. Passed by reference.

&local_work_size[]

[in][out] The size of the local tasks subset in the group. Passed by reference.

Return Value

In case of successful execution, returns true, otherwise - false.

GetContext

Returns handle of the OpenCL context.

```
int GetContext();
```

Return Value

Handle of the OpenCL context.

GetKernel

Returns handle of the kernel object at the specified index.

```
int GetKernel(  
    const int kernel_index    // index of the kernel  
);
```

Parameters

kernel_index

[in] Index of the kernel object.

Return Value

Handle of the kernel object.

GetKernelName

Returns name of the kernel object at the specified index.

```
string GetKernelName(  
    const int kernel_index    // index of the kernel  
);
```

Parameters

kernel_index

[in] Index of the kernel object.

Return Value

Name of the kernel object.

GetProgram

Returns handle of the OpenCL program.

```
int GetProgram();
```

Return Value

Handle of the OpenCL program.

Initialize

Initializes the OpenCL program.

```
bool Initialize(  
    const string program,           // handle of the OpenCL program  
    const bool show_log=true       // keep a log  
);
```

Parameters

program

[in] Handle of the OpenCL program.

show_log=true

[in] Enable logging messages.

Return Value

Returns true, if the initialization succeeded. Otherwise, it returns false.

KernelCreate

Creates an entry point into the OpenCL program at the specified index.

```
bool KernelCreate(  
    const int    kernel_index,    // index of the kernel  
    const string kernel_name      // name of the kernel  
);
```

Parameters

kernel_index

[in] Index of the kernel object.

kernel_name

[in] Name of the kernel object.

Return Value

In case of successful execution, returns true, otherwise - false.

KernelFree

Removes an OpenCL start function at the specified index.

```
bool KernelFree(  
    const int kernel_index    // index of the kernel  
);
```

Parameters

kernel_index

[in] Index of the kernel object.

Return Value

In case of successful execution, returns true, otherwise - false.

SetArgument

Sets a parameter for the OpenCL function at the specified index.

```
template<typename T>
bool SetArgument (
    const int kernel_index,    // index of the kernel
    const int arg_index,      // index of the function argument
    T value                    // source code
);
```

Parameters

kernel_index

[in] Index of the kernel object.

arg_index

[in] Index of the function argument.

value

[in] The value of the function argument.

Return Value

In case of successful execution, returns true, otherwise - false.

SetArgumentBuffer

Sets an OpenCL buffer as a parameter of the OpenCL function at the specified index.

```
bool SetArgumentBuffer(  
    const int kernel_index,    // index of the kernel  
    const int arg_index,      // index of the function argument  
    const int buffer_index    // buffer index  
);
```

Parameters

kernel_index

[in] Index of the kernel object.

arg_index

[in] Index of the function argument.

buffer_index

[in] Index buffer.

Return Value

In case of successful execution, returns true, otherwise - false.

SetArgumentLocalMemory

Sets a parameter in local memory for the OpenCL function at the specified index.

```
bool SetArgumentLocalMemory(  
    const int kernel_index,           // index of the kernel  
    const int arg_index,             // index of the function argument  
    const int local_memory_size      // size of the local memory  
);
```

Parameters

kernel_index

[in] Index of the kernel object.

arg_index

[in] Index of the function argument.

local_memory_size

[in] Size of the local memory.

Return Value

In case of successful execution, returns true, otherwise - false.

SetBuffersCount

Sets the number of buffers.

```
bool SetBuffersCount(  
    const int total_buffers    // number of buffers  
);
```

Parameters

total_buffers

[in] The total number of buffers.

Return Value

In case of successful execution, returns true, otherwise - false.

SetKernelsCount

Sets the number of kernel objects.

```
bool SetKernelsCount(  
    const int total_kernels    // number of kernels  
);
```

Parameters

total_kernels

[in] The total number of kernels.

Return Value

In case of successful execution, returns true, otherwise - false.

Shutdown

Unloads the OpenCL program.

```
void Shutdown();
```

Return Value

No return value.

SupportDouble

Checks if floating point data types are supported on the device.

```
bool SupportDouble();
```

Return Value

Returns true, if the device supports floating point data types.

Basic Class CObject

Class CObject is the base class for constructing a MQL5 Standard Library.

Description

Class CObject allows all its descendants to be part of a linked list. Also, a number of virtual methods for further implementation in descendant classes are identified.

Declaration

```
class CObject
```

Title

```
#include <Object.mqh>
```

Inheritance hierarchy

CObject

Direct descendants

[CAccountInfo](#), [CArray](#), [CChart](#), [CChartObject](#), [CCurve](#), [CDealInfo](#), [CDictionary_Obj_Double](#), [CDictionary_Obj_Obj](#), [CDictionary_String_Obj](#), [CExpertBase](#), [CFile](#), [CHistoryOrderInfo](#), [CList](#), [COrderInfo](#), [CPositionInfo](#), [CString](#), [CSymbolInfo](#), [CTerminalInfo](#), [CTrade](#), [CTreeNode](#), [CWnd](#), [ICondition](#), [IExpression](#), [IMembershipFunction](#), [INamedValue](#), [IParsableRule](#)

Class Methods by Groups

Attributes	
Prev	Gets the value of the previous item
Prev	Sets the value of the previous item
Next	Gets the value of the subsequent element
Next	Sets the next element
Compare methods	
virtual Compare	Returns the result of comparison with another object
Input/output	
virtual Save	Writes object to a file
virtual Load	Reads the object from the file
virtual Type	Returns the type of object

Prev

Gets a pointer to the previous element in the list.

```
CObject* Prev()
```

Return Value

Pointer to the previous element in the list. If an item is listed first, then return NULL.

Example:

```
//--- example for CObject::Prev()
#include <Object.mqh>
//---
void OnStart()
{
    CObject *object_first,*object_second;
    //---
    object_first=new CObject;
    if(object_first==NULL)
    {
        printf("Object create error");
        return;
    }
    object_second=new CObject;
    if(object_second==NULL)
    {
        printf("Object create error");
        delete object_first;
        return;
    }
    //--- set interconnect
    object_first.Next(object_second);
    object_second.Prev(object_first);
    //--- use prev object
    CObject *object=object_second.Prev();
    //--- delete objects
    delete object_first;
    delete object_second;
}
```

Prev

Sets the pointer to the previous element in the list.

```
void Prev(  
    CObject* object    // Pointer to the previous element in the list  
)
```

Parameters

object

[in] New value of the pointer to the previous element in the list.

Example:

```
///--- example for CObject::Prev(CObject*)  
#include <Object.mqh>  
///---  
void OnStart()  
{  
    CObject *object_first,*object_second;  
    ///---  
    object_first=new CObject;  
    if(object_first==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    object_second=new CObject;  
    if(object_second==NULL)  
    {  
        printf("Object create error");  
        delete object_first;  
        return;  
    }  
    ///--- set interconnect  
    object_first.Next(object_second);  
    object_second.Prev(object_first);  
    ///--- use objects  
    ///--- ...  
    ///--- delete objects  
    delete object_first;  
    delete object_second;  
}
```

Next

Gets a pointer to the next element in the list.

```
CObject* Next()
```

Return Value

Pointer to the next element in the list. If this is the last element in the list, return NULL.

Example:

```
//--- example for CObject::Next()
#include <Object.mqh>
//---
void OnStart()
{
    CObject *object_first,*object_second;
    //---
    object_first=new CObject;
    if(object_first==NULL)
    {
        printf("Object create error");
        return;
    }
    object_second=new CObject;
    if(object_second==NULL)
    {
        printf("Object create error");
        delete object_first;
        return;
    }
    //--- set interconnect
    object_first.Next(object_second);
    object_second.Prev(object_first);
    //--- use next object
    CObject *object=object_first.Next();
    //--- delete objects
    delete object_first;
    delete object_second;
}
```

Next

Sets the pointer to the next element in the list.

```
void Next(  
    CObject* object    // Pointer to the next element in the list  
)
```

Parameters

object

[in] New value of the pointer to the next element in the list.

Example:

```
//--- example for CObject::Next(CObject*)  
#include <Object.mqh>  
//---  
void OnStart()  
{  
    CObject *object_first,*object_second;  
    //---  
    object_first=new CObject;  
    if(object_first==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    object_second=new CObject;  
    if(object_second==NULL)  
    {  
        printf("Object create error");  
        delete object_first;  
        return;  
    }  
    //--- set interconnect  
    object_first.Next(object_second);  
    object_second.Prev(object_first);  
    //--- use objects  
    //--- ...  
    //--- delete objects  
    delete object_first;  
    delete object_second;  
}
```

Compare

Compares the data on a list element with data on another list element.

```
virtual int Compare(  
    const CObject* node,      // element  
    const int      mode=0     // variant  
) const
```

Parameters

node

[in] Pointer to a list element to compare

mode=0

[in] Comparison variant

Return Value

0 - in case the list elements are equal, -1 - if the list element is less than the element used for comparison (node), 1 - if the list element is greater than the element used for comparison (node).

Note

Compare() method in CObject class always returns 0 and does not perform any action. If you want to compare data in derived class, the Compare(...) method should be implemented. The 'mode' parameter should be used when implementing multivariate comparison.

Example:

```
//--- example for CObject::Compare(...)  
#include <Object.mqh>  
//---  
void OnStart()  
{  
    CObject *object_first,*object_second;  
    //---  
    object_first=new CObject;  
    if(object_first==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    object_second=new CObject;  
    if(object_second==NULL)  
    {  
        printf("Object create error");  
        delete object_first;  
        return;  
    }  
    //--- set interconnect  
    object_first.Next(object_second);
```

```
object_second.Prev(object_first);  
//--- compare objects  
int result=object_first.Compare(object_second);  
//--- delete objects  
delete object_first;  
delete object_second;  
}
```

Save

Saves list element data in a file.

```
virtual bool Save(  
    int file_handle    // File handle  
)
```

Parameters

file_handle

[in] Handle of the binary file opened earlier using the FileOpen () function

Return Value

true - successfully completed, false - error.

Note

Save(int) method in CObject class always returns 'true' and does not perform any action. If you want to save the data of a derived class in a file, the Save(int) method should be implemented.

Example:

```
//--- example for CObject::Save(int)  
#include <Object.mqh>  
//---  
void OnStart()  
{  
    int file_handle;  
    CObject *object=new CObject;  
    //---  
    if(object!=NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- set objects data  
    //--- . . .  
    //--- open file  
    file_handle=FileOpen("MyFile.bin",FILE_WRITE|FILE_BIN|FILE_ANSI);  
    if(file_handle>=0)  
    {  
        if(!object.Save(file_handle))  
        {  
            //--- file save error  
            printf("File save: Error %d!",GetLastError());  
            delete object;  
            FileClose(file_handle);  
            //---  
            return;  
        }  
    }  
}
```

```
        FileClose(file_handle);  
    }  
    delete object;  
}
```

Load

Loads list element data from a file.

```
virtual bool Load(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] Handle of the binary file opened earlier using the FileOpen() function.

Return Value

true - successfully completed, false - error.

Note

Load(int) method in the CObject class always returns 'true' and does not perform any action. If you want to load the data of a derived class from a file, the Load(int) method should be implemented.

Example:

```
//--- example for CObject::Load(int)  
#include <Object.mqh>  
//---  
void OnStart()  
{  
    int file_handle;  
    CObject *object=new CObject;  
    //---  
    if(object!=NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- open file  
    file_handle=FileOpen("MyFile.bin",FILE_READ|FILE_BIN|FILE_ANSI);  
    if(file_handle>=0)  
    {  
        if(!object.Load(file_handle))  
        {  
            //--- file load error  
            printf("File load: Error %d!",GetLastError());  
            delete object;  
            FileClose(file_handle);  
            //---  
            return;  
        }  
        FileClose(file_handle);  
    }  
}
```

```
//--- use object  
//--- . . .  
delete object;  
}
```

Type

Gets the type identifier.

```
virtual int Type() const
```

Return Value

Type identifier (for CObject - 0).

Example:

```
//--- example for CObject::Type()
#include <Object.mqh>
//---
void OnStart()
{
    CObject *object=new CObject;
    //---
    object=new CObject;
    if(object ==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- get objects type
    int type=object.Type();
    //--- delete object
    delete object;
}
```

Data Structures

This section contains the technical details on working with various data structures (arrays, linked lists, etc.) and description of the relevant components of the MQL5 Standard Library.

Using classes of data structures will save time when creating custom data stores of various formats (including composite data structures).

MQL5 Standard Library (in terms of data sets) is placed in the working directory of the terminal in the Include\Arrays folder.

Data Arrays

Use of classes of dynamic data arrays will save time when creating a custom data stores of various formats (including multidimensional arrays).

MQL5 Standard Library (in terms of arrays of data) is located in the working directory of the terminal in the Include\Arrays folder.

Class	Description
<u>CArray</u>	Base class of dynamic data array
<u>CArrayChar</u>	Dynamic array of char or uchar variables
<u>CArrayShort</u>	Dynamic array of short or ushort variables
<u>CArrayInt</u>	Dynamic array of int or uint variables
<u>CArrayLong</u>	Dynamic array of long or ulong variables
<u>CArrayFloat</u>	Dynamic array of float variables
<u>CArrayDouble</u>	Dynamic array of double variables
<u>CArrayString</u>	Dynamic array of string variables
<u>CArrayObj</u>	Dynamic array of <u>CObject</u> pointers
<u>CList</u>	Provides the ability to work with a list of instances of <u>CObject</u> class and its descendants
<u>CTreeNode</u>	Provides the ability to work with nodes of the <u>CTree</u> binary tree
<u>CTree</u>	Provides the ability to work with the binary tree of the <u>CTreeNode</u> class instances and its descendants

CArray

CArray class is the base class of a dynamic array of variables.

Description

Class CArray is intended to operate on dynamic arrays of variables: memory allocation, sorting, and working with files.

Declaration

```
class CArray : public CObject
```

Title

```
#include <Arrays\Array.mqh>
```

Inheritance hierarchy

CObject

CArray

Direct descendants

CArrayChar, CArrayDouble, CArrayFloat, CArrayInt, CArrayLong, CArrayObj, CArrayShort, CArrayString

Class Methods by Groups

Attributes	
<u>Step</u>	Gets the increment size of the array
<u>Step</u>	Sets the increment size of the array
<u>Total</u>	Gets the number of elements in the array
<u>Available</u>	Gets the number of free elements of the array that are available without additional memory allocation
<u>Max</u>	Gets the maximum possible size of the array without memory reallocation
<u>IsSorted</u>	Gets the flag of array being sorted using specified sorting mode
<u>SortMode</u>	Gets the sorting mode for an array
Clear methods	
<u>Clear</u>	Deletes all of the array elements without memory release
Sort methods	

Sort	Sorts an array to the specified option
Input/output	
virtual Save	Saves data array in a file
virtual Load	Loads data array from a file

Methods inherited from class CObject

Prev, Prev, Next, Next, [Type](#), [Compare](#)

Step

Gets the increment size of the array.

```
int Step() const
```

Return Value

Increment size of the array.

Example:

```
//--- example for CArray::Step()
#include <Arrays\Array.mqh>
//---
void OnStart()
{
    CArray *array=new CArray;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- get resize step
    int step=array.Step();
    //--- use array
    //--- ...
    //--- delete array
    delete array;
}
```

Step

Sets the increment size of the array.

```
bool Step(  
    int step    // step  
)
```

Parameters

step

[in] The new value of the increment size of the array.

Return Value

true - successful, false - there was an attempt to establish a step less than or equal to zero.

Example:

```
//--- example for CArray::Step(int)  
#include <Arrays\Array.mqh>  
//---  
void OnStart()  
{  
    CArray *array=new CArray;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- set resize step  
    bool result=array.Step(1024);  
    //--- use array  
    //--- ...  
    //--- delete array  
    delete array;  
}
```

Total

Gets the number of elements in the array.

```
int Total() const;
```

Return Value

Number of elements in the array.

Example:

```
//--- example for CArray::Total()
#include <Arrays\Array.mqh>
//---
void OnStart()
{
    CArray *array=new CArray;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- check total
    int total=array.Total();
    //--- use array
    //--- ...
    //--- delete array
    delete array;
}
```

Available

Gets the number of free elements of the array that are available without additional memory allocation.

```
int Available() const
```

Return Value

Number of free elements of the array available without additional memory allocation.

Example:

```
//--- example for CArray::Available()
#include <Arrays\Array.mqh>
//---
void OnStart()
{
    CArray *array=new CArray;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- check available
    int available=array.Available();
    //--- use array
    //--- ...
    //--- delete array
    delete array;
}
```

Max

Gets the maximum possible size of the array without memory reallocation.

```
int Max() const
```

Return Value

The maximum possible size of the array without memory reallocation.

Example:

```
//--- example for CArray::Max()
#include <Arrays\Array.mqh>
//---
void OnStart()
{
    CArray *array=new CArray;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- check maximum size
    int max=array.Max();
    //--- use array
    //--- ...
    //--- delete array
    delete array;
}
```

IsSorted

Gets the flag of array being sorted using the specified sorting mode.

```
bool IsSorted(  
    int mode=0      // sorting mode  
) const
```

Parameters

mode=0

[in] Tested sorting mode.

Return Value

Flag of the sorted list. If the list is sorted using the specified mode - true, otherwise - false.

Note

The sort flag cannot be changed directly. It is set by the Sort() method and reset by any add/insert method except for the InsertSort(...).

Example:

```
///--- example for CArray::IsSorted()  
#include <Arrays\Array.mqh>  
///---  
void OnStart()  
{  
    CArray *array=new CArray;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- check sorted  
    if(array.IsSorted())  
    {  
        ///--- use methods for sorted array  
        ///--- ...  
    }  
    ///--- delete array  
    delete array;  
}
```

SortMode

Gets the sorting mode for an array.

```
int SortMode() const;
```

Return Value

Sorting mode.

Example:

```
//--- example for CArray::SortMode()
#include <Arrays\Array.mqh>
//---
void OnStart()
{
    CArray *array=new CArray;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- check sort mode
    int sort_mode=array.SortMode();
    //--- use array
    //--- ...
    //--- delete array
    delete array;
}
```

Clear

Deletes all of the array elements without memory release.

```
void Clear()
```

Return Value

None.

Example:

```
//--- example for CArray::Clear()
#include <Arrays\Array.mqh>
//---
void OnStart()
{
    CArray *array=new CArray;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- use array
    //--- ...
    //--- clear array
    array.Clear();
    //--- delete array
    delete array;
}
```

Sort

Sorts an array using the specified option.

```
void Sort(  
    int mode=0      // sorting mode  
)
```

Parameters

mode=0

[in] Mode of array sorting.

Return Value

No.

Note

Sorting an array is always ascending. For arrays of primitive data types (CArrayChar, CArrayShort, etc.), the 'mode' parameter is not used. For the CArrayObj array, multivariate sorting should be implemented in the Sort(int) method of derived classes.

Example:

```
//--- example for CArray::Sort(int)  
#include <Arrays\Array.mqh>  
//---  
void OnStart()  
{  
    CArray *array=new CArray;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- sorting by mode 0  
    array.Sort(0);  
    //--- use array  
    //--- ...  
    //--- delete array  
    delete array;  
}
```

Save

Saves data array in the file.

```
virtual bool Save(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] Handle of a binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CArray::Save(int)  
#include <Arrays\Array.mqh>  
//---  
void OnStart()  
{  
    int file_handle;  
    CArray *array=new CArray;  
    //---  
    if(array!=NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- open file  
    file_handle=FileOpen("MyFile.bin",FILE_WRITE|FILE_BIN|FILE_ANSI);  
    if(file_handle>=0)  
    {  
        if(!array.Save(file_handle))  
        {  
            //--- file save error  
            printf("File save: Error %d!",GetLastError());  
            delete array;  
            FileClose(file_handle);  
            //---  
            return;  
        }  
        FileClose(file_handle);  
    }  
    //--- delete array  
    delete array;  
}
```

Load

Loads data array from a file.

```
virtual bool Load(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] Handle of a binary file previously opened using the FileOpen () function.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CArray::Load(...)  
#include <Arrays\Array.mqh>  
//---  
void OnStart()  
{  
    int file_handle;  
    CArray *array=new CArray;  
    //---  
    if(array!=NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- open file  
    file_handle=FileOpen("MyFile.bin",FILE_READ|FILE_BIN|FILE_ANSI);  
    if(file_handle>=0)  
    {  
        if(!array.Load(file_handle))  
        {  
            //--- file load error  
            printf("File load: Error %d!",GetLastError());  
            delete array;  
            FileClose(file_handle);  
            //---  
            return;  
        }  
        FileClose(file_handle);  
    }  
    //--- delete array  
    delete array;  
}
```

CArrayChar

CArrayChar is a class of dynamic array of char or uchar variables.

Description

CArrayChar class provides the ability to work with a dynamic array of char or uchar variables. The class allows adding/inserting/deleting array elements, performing an array sorting, and searching in a sorted array. In addition, methods of working with files have been implemented.

Declaration

```
class CArrayChar : public CArray
```

Title

```
#include <Arrays\ArrayChar.mqh>
```

Inheritance hierarchy

[CObject](#)

[CArray](#)

CArrayChar

Class Methods

Memory control	
Reserve	Allocates memory to increase the size of the array
Resize	Sets a new (smaller) size of the array
Shutdown	Clears the array with a full memory release
Add methods	
Add	Adds an element to the end of the array
AddArray	Adds elements of one array to the end of another
AddArray	Adds elements of one array to the end of another
Insert	Inserts an element to the specified position in the array
InsertArray	Inserts to an array elements from another array from the specified position
InsertArray	Inserts to an array elements from another array from the specified position
AssignArray	Copies the elements of one array to another

AssignArray	Copies the elements of one array to another
Modify methods	
Update	Changes the element at the specified array position
Shift	Moves an element from a given position in the array to the specified offset
Delete methods	
Delete	Removes the element from the specified array position
DeleteRange	Deletes a group of elements from the specified array position
Access methods	
At	Gets the element from the specified array position
Compare methods	
CompareArray	Compares the array with another one
CompareArray	Compares the array with another one
Sorted array methods	
InsertSort	Inserts an element in a sorted array
Search	Searches for an element equal to the sample in the sorted array
SearchGreat	Searches for an element with a value exceeding the value of the sample in the sorted array
SearchLess	Searches for an element with a value less than the value of the sample in the sorted array
SearchGreatOrEqual	Searches for an element with a value greater than or equal to the value of the sample in the sorted array
SearchLessOrEqual	Searches for an element with a value less than or equal to the value of the sample in the sorted array
SearchFirst	Searches for the first element equal to the sample in the sorted array
SearchLast	Searches for the last element equal to the sample in the sorted array
SearchLinear	Searches for the element equal to the sample in the array

Input/output	
virtual Save	Saves data array in the file
virtual Load	Loads data array from the file
virtual Type	Gets the array type identifier

Methods inherited from class CObject

Prev, Prev, Next, Next, [Compare](#)

Methods inherited from class CArray

[Step](#), [Step](#), [Total](#), [Available](#), [Max](#), [IsSorted](#), [SortMode](#), [Clear](#), [Sort](#)

Reserve

Allocates memory to increase the size of the array.

```
bool Reserve (
    int size      // number
)
```

Parameters

size

[in] The number of additional elements of the array.

Return Value

true - successful, false - there was an attempt to request for an amount less than or equal to zero, or failed to increase the array.

Note

To reduce fragmentation of memory, the array size is increased by the step previously determined by the Step(int) method or the default step of 16.

Example:

```
///--- example for CArrayChar::Reserve(int)
#include <Arrays\ArrayChar.mqh>
///---
void OnStart()
{
    CArrayChar *array=new CArrayChar;
    ///---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    ///--- reserve memory
    if(!array.Reserve(1024))
    {
        printf("Reserve error");
        delete array;
        return;
    }
    ///--- use array
    ///--- . . .
    ///--- delete array
    delete array;
}
```

Resize

Sets a new (smaller) size of the array.

```
bool Resize(  
    int size    // size  
)
```

Parameters

size

[in] New size of the array.

Return Value

true - successful, false - there was an attempt to set the size less than or equal to zero.

Note

Changing the size of the array allows using the memory optimally. Excessive elements on the right are lost. To reduce fragmentation of memory, the array size is changed by the step previously determined by the Step(int) method or the default step of 16.

Example:

```
///--- example for CArrayChar::Resize(int)  
#include <Arrays\ArrayChar.mqh>  
///---  
void OnStart()  
{  
    CArrayChar *array=new CArrayChar;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- resize array  
    if(!array.Resize(10))  
    {  
        printf("Resize error");  
        delete array;  
        return;  
    }  
    ///--- delete array  
    delete array;  
}
```

Shutdown

Clears the array with a full memory release.

```
bool Shutdown()
```

Return Value

true - successful, false - error.

Example:

```
//--- example for CArrayChar::Shutdown()
#include <Arrays\ArrayChar.mqh>
//---
void OnStart()
{
    CArrayChar *array=new CArrayChar;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- . . .
    //--- shutdown array
    if(!array.Shutdown())
    {
        printf("Shutdown error");
        delete array;
        return;
    }
    //--- delete array
    delete array;
}
```

Add

Adds an element to the end of the array.

```
bool Add(  
    char element    // element to add  
)
```

Parameters

element

[in] Value of the element to add to the array.

Return Value

true - successful, false - cannot add an element.

Example:

```
///--- example for CArrayChar::Add(char)  
#include <Arrays\ArrayChar.mqh>  
///---  
void OnStart()  
{  
    CArrayChar *array=new CArrayChar;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    for(int i=0;i<100;i++)  
    {  
        if(!array.Add(i))  
        {  
            printf("Element addition error");  
            delete array;  
            return;  
        }  
    }  
    ///--- use array  
    ///--- . . .  
    ///--- delete array  
    delete array;  
}
```

AddArray

Adds elements of one array to the end of another.

```
bool AddArray(  
    const char& src[]      // source array  
)
```

Parameters

src[]

[in] Reference to an array of source elements to add.

Return Value

true - successful, false - cannot add items.

Example:

```
///--- example for CArrayChar::AddArray(const char &[])  
#include <Arrays\ArrayChar.mqh>  
///---  
char src[];  
///---  
void OnStart()  
{  
    CArrayChar *array=new CArrayChar;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add another array  
    if(!array.AddArray(src))  
    {  
        printf("Array addition error");  
        delete array;  
        return;  
    }  
    ///--- use array  
    ///--- . . .  
    ///--- delete array  
    delete array;  
}
```

AddArray

Adds elements of one array to the end of another.

```
bool AddArray(  
    const CArrayChar* src      // pointer to the source  
)
```

Parameters

src

[in] Pointer to an instance of CArrayChar class used as a source of elements to add.

Return Value

true - successful, false - cannot add items.

Example:

```
///--- example for CArrayChar::AddArray(const CArrayChar*)  
#include <Arrays\ArrayChar.mqh>  
///---  
void OnStart()  
{  
    CArrayChar *array=new CArrayChar;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- create source array  
    CArrayChar *src=new CArrayChar;  
    if(src==NULL)  
    {  
        printf("Object create error");  
        delete array;  
        return;  
    }  
    ///--- add source arrays elements  
    ///--- . . .  
    ///--- add another array  
    if(!array.AddArray(src))  
    {  
        printf("Array addition error");  
        delete src;  
        delete array;  
        return;  
    }  
    ///--- delete source array  
    delete src;
```

```
//--- use array  
//--- . . .  
//--- delete array  
delete array;  
}
```

Insert

Inserts an element to the specified position in the array.

```
bool Insert(  
    char element,    // element to insert  
    int pos          // position  
)
```

Parameters

element

[in] Value of the element to be inserted into the array

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert the element.

Example:

```
//--- example for CArrayChar::Insert(char,int)  
#include <Arrays\ArrayChar.mqh>  
//---  
void OnStart()  
{  
    CArrayChar *array=new CArrayChar;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- insert elements  
    for(int i=0;i<100;i++)  
    {  
        if(!array.Insert(i,0))  
        {  
            printf("Insert error");  
            delete array;  
            return;  
        }  
    }  
    //--- use array  
    //--- . . .  
    //--- delete array  
    delete array;  
}
```

InsertArray

Inserts elements of one array from the specified position of another array.

```
bool  InsertArray(  
    const char&  src[],      // source array  
    int          pos        // position  
)
```

Parameters

src[]

[in] Reference to an array used as a source of elements to insert

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert items.

Example:

```
//--- example for CArrayChar::InsertArray(const char &[],int)  
#include <Arrays\ArrayChar.mqh>  
//---  
char src[];  
//---  
void OnStart()  
{  
    CArrayChar *array=new CArrayChar;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- insert another array  
    if(!array.InsertArray(src,0))  
    {  
        printf("Array inserting error");  
        delete array;  
        return;  
    }  
    //--- use array  
    //--- . . .  
    //--- delete array  
    delete array;  
}
```

InsertArray

Inserts elements of one array from the specified position of another array.

```
bool InsertArray(  
    CArrayChar* src,      // pointer to the source  
    int pos              // position  
)
```

Parameters

src

[in] Pointer to an instance of the CArrayChar class used as a source of elements to insert.

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert items.

Example:

```
//--- example for CArrayChar::InsertArray(const CArrayChar*,int)  
#include <Arrays\ArrayChar.mqh>  
//---  
void OnStart()  
{  
    CArrayChar *array=new CArrayChar;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- create source array  
    CArrayChar *src=new CArrayChar;  
    if(src==NULL)  
    {  
        printf("Object create error");  
        delete array;  
        return;  
    }  
    //--- add source arrays elements  
    //--- . . .  
    //--- insert another array  
    if(!array.InsertArray(src,0))  
    {  
        printf("Array inserting error");  
        delete src;  
        delete array;  
    }  
}
```

```
        return;  
    }  
    //--- delete source array  
    delete src;  
    //--- use array  
    //--- . . .  
    //--- delete array  
    delete array;  
}
```

AssignArray

Copies the elements of one array to another.

```
bool AssignArray(  
    const char& src[]      // source array  
)
```

Parameters

src[]

[in] Reference to an array used as a source of elements to copy.

Return Value

true - successful, false - cannot copy the items.

Example:

```
///--- example for CArrayChar::AssignArray(const char &[])  
#include <Arrays\ArrayChar.mqh>  
///---  
char src[];  
///---  
void OnStart()  
{  
    CArrayChar *array=new CArrayChar;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- assign another array  
    if(!array.AssignArray(src))  
    {  
        printf("Array assigned error");  
        delete array;  
        return;  
    }  
    ///--- use array  
    ///--- . . .  
    ///--- delete array  
    delete array;  
}
```

AssignArray

Copies the elements of one array to another.

```
bool AssignArray(  
    const CArrayChar* src      // pointer to the source  
)
```

Parameters

src

[in] Pointer to an instance of the CArrayChar class used as a source of elements to copy.

Return Value

true - successful, false - cannot copy the elements.

Example:

```
///--- example for CArrayChar::AssignArray(const CArrayChar*)  
#include <Arrays\ArrayChar.mqh>  
///---  
void OnStart()  
{  
    CArrayChar *array=new CArrayChar;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- create source array  
    CArrayChar *src =new CArrayChar;  
    if(src==NULL)  
    {  
        printf("Object create error");  
        delete array;  
        return;  
    }  
    ///--- add source arrays elements  
    ///--- . . .  
    ///--- assign another array  
    if(!array.AssignArray(src))  
    {  
        printf("Array assigned error");  
        delete src;  
        delete array;  
        return;  
    }  
    ///--- arrays are identical  
    ///--- delete source array
```

```
delete src;  
//--- use array  
//--- . . .  
//--- delete array  
delete array;  
}
```

Update

Changes the element at the specified array position.

```
bool Update(  
    int    pos,           // position  
    char   element       // value  
)
```

Parameters

pos

[in] Position of the element in the array to change

element

[in] New value of the element

Return Value

true - successful, false - cannot change the element.

Example:

```
//--- example for CArrayChar::Update(int,char)  
#include <Arrays\ArrayChar.mqh>  
//---  
void OnStart()  
{  
    CArrayChar *array=new CArrayChar;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- update element  
    if(!array.Update(0,'A'))  
    {  
        printf("Update error");  
        delete array;  
        return;  
    }  
    //--- delete array  
    delete array;  
}
```

Shift

Moves an item from a given position in the array to the specified offset.

```
bool Shift(  
    int pos,          // position  
    int shift         // value  
)
```

Parameters

pos

[in] Position of the moved element in the array

shift

[in] The shift value (both positive and negative).

Return Value

true - successful, false - cannot move the element.

Example:

```
//--- example for CArrayChar::Shift(int,int)  
#include <Arrays\ArrayChar.mqh>  
//---  
void OnStart()  
{  
    CArrayChar *array=new CArrayChar;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- shift element  
    if(!array.Shift(10,-5))  
    {  
        printf("Shift error");  
        delete array;  
        return;  
    }  
    //--- delete array  
    delete array;  
}
```

Delete

Removes the element from the specified array position.

```
bool Delete(  
    int pos    // position  
)
```

Parameters

pos

[in] Position of the array element to be removed.

Return Value

true - successful, false - cannot remove the element.

Example:

```
///--- example for CArrayChar::Delete(int)  
#include <Arrays\ArrayChar.mqh>  
///---  
void OnStart()  
{  
    CArrayChar *array=new CArrayChar;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- delete element  
    if(!array.Delete(0))  
    {  
        printf("Delete error");  
        delete array;  
        return;  
    }  
    ///--- delete array  
    delete array;  
}
```

DeleteRange

Deletes a group of elements from the specified array position.

```
bool DeleteRange(  
    int from,      // position of the first element  
    int to         // position of the last element  
)
```

Parameters

from

[in] Position of the first array element to be removed.

to

[in] Position of the last array element to be removed.

Return Value

true - successful, false - cannot remove the elements.

Example:

```
//--- example for CArrayChar::DeleteRange(int,int)  
#include <Arrays\ArrayChar.mqh>  
//---  
void OnStart()  
{  
    CArrayChar *array=new CArrayChar;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- delete elements  
    if(!array.DeleteRange(0,10))  
    {  
        printf("Delete error");  
        delete array;  
        return;  
    }  
    //--- delete array  
    delete array;  
}
```

At

Gets the element from the specified array position.

```
char At(  
    int pos    // position  
    ) const
```

Parameters

pos

[in] Position of the desired element in the array.

Return Value

The value of the element - success, CHAR_MAX - there was an attempt to get an element from a non-existing position (the last error code is ERR_OUT_OF_RANGE).

Note

Of course, CHAR_MAX may be a valid value of an array element. Therefore, always check the last error code after receiving such a value.

Example:

```
///--- example for CArrayChar::At(int)  
#include <Arrays\ArrayChar.mqh>  
///---  
void OnStart()  
{  
    CArrayChar *array=new CArrayChar;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    for(int i=0;i<array.Total();i++)  
    {  
        char result=array.At(i);  
        if(result==CHAR_MAX && GetLastError()==ERR_OUT_OF_RANGE)  
        {  
            ///--- error of reading from array  
            printf("Get element error");  
            delete array;  
            return;  
        }  
        ///--- use element  
        ///--- . . .  
    }  
}
```

```
//--- delete array  
delete array;  
}
```

CompareArray

Compares the array with another one.

```
bool CompareArray(  
    const char& src[]      // source array  
    ) const
```

Parameters

src[]

[in] Reference to an array used as a source of elements for comparison.

Return Value

true - arrays are equal, false - arrays are not equal.

Example:

```
//--- example for CArrayChar::CompareArray(const char &[])  
#include <Arrays\ArrayChar.mqh>  
//---  
char src[];  
//---  
void OnStart()  
{  
    CArrayChar *array=new CArrayChar;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- compare with another array  
    int result=array.CompareArray(src);  
    //--- delete array  
    delete array;  
}
```

CompareArray

Compares the array with another one.

```
bool CompareArray(  
    const CArrayChar* src      // pointer to the source  
    ) const
```

Parameters

src

[in] Pointer to an instance of the CArrayChar class used as a source of elements for comparison.

Return Value

true - arrays are equal, false - arrays are not equal.

Example:

```
///--- example for CArrayChar::CompareArray(const CArrayChar*)  
#include <Arrays\ArrayChar.mqh>  
///---  
void OnStart()  
{  
    CArrayChar *array=new CArrayChar;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- create source array  
    CArrayChar *src=new CArrayChar;  
    if(src==NULL)  
    {  
        printf("Object create error");  
        delete array;  
        return;  
    }  
    ///--- add source arrays elements  
    ///--- . . .  
    ///--- compare with another array  
    int result=array.CompareArray(src);  
    ///--- delete arrays  
    delete src;  
    delete array;  
}
```

InsertSort

Inserts an element in a sorted array.

```
bool InsertSort(  
    char element    // element to insert  
)
```

Parameters

element

[in] Value of the element to be inserted into a sorted array

Return Value

true - successful, false - cannot insert the element.

Example:

```
///--- example for CArrayChar::InsertSort(char)  
#include <Arrays\ArrayChar.mqh>  
///---  
void OnStart()  
{  
    CArrayChar *array=new CArrayChar;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- sort array  
    array.Sort();  
    ///--- insert element  
    if(!array.InsertSort('A'))  
    {  
        printf("Insert error");  
        delete array;  
        return;  
    }  
    ///--- delete array  
    delete array;  
}
```

Search

Searches for an element equal to the sample in the sorted array.

```
int Search(  
    char element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayChar::Search(char)  
#include <Arrays\ArrayChar.mqh>  
//---  
void OnStart()  
{  
    CArrayChar *array=new CArrayChar;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.Search('A')!=-1) printf("Element found");  
    else                      printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchGreat

Searches for an element with a value exceeding the value of the sample in the sorted array.

```
int SearchGreat(  
    char element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element, if successful, -1 - the element not found.

Example:

```
//--- example for CArrayChar::SearchGreat(char)  
#include <Arrays\ArrayChar.mqh>  
//---  
void OnStart()  
{  
    CArrayChar *array=new CArrayChar;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.SearchGreat('A')!=-1) printf("Element found");  
    else                          printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchLess

Searches for an element with a value less than the value of the sample in the sorted array.

```
int SearchLess(  
    char element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayChar::SearchLess(char)  
#include <Arrays\ArrayChar.mqh>  
//---  
void OnStart()  
{  
    CArrayChar *array=new CArrayChar;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.SearchLess('A')!=-1) printf("Element found");  
    else                          printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchGreatOrEqual

Searches for an element with a value greater than or equal to the value of the sample in the sorted array.

```
int SearchGreatOrEqual(  
    char element    // sample  
) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
///--- example for CArrayChar::SearchGreatOrEqual(char)  
#include <Arrays\ArrayChar.mqh>  
///---  
void OnStart()  
{  
    CArrayChar *array=new CArrayChar;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- sort array  
    array.Sort();  
    ///--- search element  
    if(array.SearchGreatOrEqual('A')!=-1) printf("Element found");  
    else                                printf("Element not found");  
    ///--- delete array  
    delete array;  
}
```

SearchLessOrEqual

Searches for an element with a value less than or equal to the value of the sample in the sorted array.

```
int SearchLessOrEqual(  
    char element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayChar::SearchLessOrEqual(char)  
#include <Arrays\ArrayChar.mqh>  
//---  
void OnStart()  
{  
    CArrayChar *array=new CArrayChar;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.SearchLessOrEqual('A')!=-1) printf("Element found");  
    else                                printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchFirst

Searches for the first element equal to the sample in the sorted array.

```
int SearchFirst(  
    char element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayChar::SearchFirst(char)  
#include <Arrays\ArrayChar.mqh>  
//---  
void OnStart()  
{  
    CArrayChar *array=new CArrayChar;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.SearchFirst('A')!=-1) printf("Element found");  
    else                          printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchLast

Searches for the last element equal to the sample in the sorted array.

```
int SearchLast(  
    char element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayChar::SearchLast(char)  
#include <Arrays\ArrayChar.mqh>  
//---  
void OnStart()  
{  
    CArrayChar *array=new CArrayChar;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.SearchLast('A')!=-1) printf("Element found");  
    else                          printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchLinear

Searches for the element equal to the sample in the array.

```
int SearchLinear(  
    char element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Note

The method uses the linear search (or sequential search) algorithm for unsorted arrays.

Example:

```
///--- example for CArrayChar::SearchLinear(char)  
#include <Arrays\ArrayChar.mqh>  
///---  
void OnStart()  
{  
    CArrayChar *array=new CArrayChar;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- search element  
    if(array.SearchLinear('A')!=-1) printf("Element found");  
    else                          printf("Element not found");  
    ///--- delete array  
    delete array;  
}
```

Save

Saves data array in the file.

```
virtual bool Save(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CArrayChar::Save(int)  
#include <Arrays\ArrayChar.mqh>  
//---  
void OnStart()  
{  
    int file_handle;  
    CArrayChar *array=new CArrayChar;  
    //---  
    if(array!=NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- open file  
    file_handle=FileOpen("MyFile.bin",FILE_WRITE|FILE_BIN|FILE_ANSI);  
    if(file_handle>=0)  
    {  
        if(!array.Save(file_handle))  
        {  
            //--- file save error  
            printf("File save: Error %d!",GetLastError());  
            delete array;  
            FileClose(file_handle);  
            //---  
            return;  
        }  
        FileClose(file_handle);  
    }  
    //--- delete array  
    delete array;  
}
```

Load

Loads data array from the file.

```
virtual bool Load(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CArrayChar::Load(int)  
#include <Arrays\ArrayChar.mqh>  
//---  
void OnStart()  
{  
    int file_handle;  
    CArrayChar *array=new CArrayChar;  
    //---  
    if(array!=NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- open file  
    file_handle=FileOpen("MyFile.bin",FILE_READ|FILE_BIN|FILE_ANSI);  
    if(file_handle>=0)  
    {  
        if(!array.Load(file_handle))  
        {  
            //--- file load error  
            printf("File load: Error %d!",GetLastError());  
            delete array;  
            FileClose(file_handle);  
            //---  
            return;  
        }  
        FileClose(file_handle);  
    }  
    //--- use arrays elements  
    for(int i=0;i<array.Total();i++)  
    {  
        printf("Element[%d] = '%c'",i,array.At(i));  
    }  
}
```

```
    }  
    ///--- delete array  
    delete array;  
}
```

Type

Gets the array type identifier.

```
virtual int Type() const
```

Return Value

Array type identifier (for CArrayChar - 77).

Example:

```
//--- example for CArrayChar::Type()
#include <Arrays\ArrayChar.mqh>
//---
void OnStart()
{
    CArrayChar *array=new CArrayChar;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- get array type
    int type=array.Type();
    //--- delete array
    delete array;
}
```

CArrayShort

CArrayShort is a class of dynamic array of short or ushort variables.

Description

Class CArrayShort provides the ability to work with a dynamic array of short or ushort variables. The class allows adding/inserting/deleting array elements, performing an array sorting, and searching in a sorted array. In addition, methods of working with files have been implemented.

Declaration

```
class CArrayShort : public CArray
```

Title

```
#include <Arrays\ArrayShort.mqh>
```

Inheritance hierarchy

[CObject](#)

[CArray](#)

CArrayShort

Class Methods by Groups

Memory control	
Reserve	Allocates memory to increase the size of the array
Resize	Sets a new (smaller) size of the array
Shutdown	Clears the array with a full memory release
Add methods	
Add	Adds an element to the end of the array
AddArray	Adds elements of one array to the end of another
AddArray	Adds elements of one array to the end of another
Insert	Inserts an element to the specified position in the array
InsertArray	Inserts to an array elements from another array from the specified position
InsertArray	Inserts to an array elements from another array from the specified position
AssignArray	Copies the elements of one array to another

AssignArray	Copies the elements of one array to another
Update methods	
Update	Changes the element at the specified array position
Shift	Moves an element from a given position in the array to the specified offset
Delete methods	
Delete	Removes the element from the specified array position
DeleteRange	Deletes a group of elements from the specified array position
Access methods	
At	Gets the element from the specified array position
Compare methods	
CompareArray	Compares the array with another one
CompareArray	Compares the array with another one
Sorted array operations	
InsertSort	Inserts an element in a sorted array
Search	Searches for an element equal to the sample in the sorted array
SearchGreat	Searches for an element with a value exceeding the value of the sample in the sorted array
SearchLess	Searches for an element with a value less than the value of the sample in the sorted array
SearchGreatOrEqual	Searches for an element with a value greater than or equal to the value of the sample in the sorted array
SearchLessOrEqual	Searches for an element with a value less than or equal to the value of the sample in the sorted array
SearchFirst	Searches for the first element equal to the sample in the sorted array
SearchLast	Searches for the last element equal to the sample in the sorted array
SearchLinear	Searches for the element equal to the sample in the array

Input/output	
virtual Save	Saves data array in the file
virtual Load	Loads data array from the file
virtual Type	Gets the type identifier of the array

Methods inherited from class CObject

Prev, Prev, Next, Next, [Compare](#)

Methods inherited from class CArray

[Step](#), [Step](#), [Total](#), [Available](#), [Max](#), [IsSorted](#), [SortMode](#), [Clear](#), [Sort](#)

Reserve

Allocates memory to increase the size of the array.

```
bool Reserve (
    int size      // number
)
```

Parameters

size

[in] The number of additional elements of the array.

Return Value

true - successful, false - there was an attempt to request for an amount less than or equal to zero, or failed to increase the array.

Note

To reduce fragmentation of memory, the array size is changed using the step previously determined by the Step(int) method or the default step of 16.

Example:

```
///--- example for CArrayShort::Reserve(int)
#include <Arrays\ArrayShort.mqh>
///---
void OnStart()
{
    CArrayShort *array=new CArrayShort;
    ///---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    ///--- reserve memory
    if(!array.Reserve(1024))
    {
        printf("Reserve error");
        delete array;
        return;
    }
    ///--- use array
    ///--- . . .
    ///--- delete array
    delete array;
}
```

Resize

Sets a new (smaller) size of the array.

```
bool Resize(  
    int size      // size  
)
```

Parameters

size

[in] New size of the array.

Return Value

true - successful, false - there was an attempt to set the size less than or equal to zero.

Note

Changing the size of the array allows using the memory optimally. Excessive elements on the right are lost. To reduce fragmentation of memory, the array size is changed by the step previously determined by the Step(int) method or the default step of 16.

Example:

```
///--- example for CArrayShort::Resize(int)  
#include <Arrays\ArrayShort.mqh>  
///---  
void OnStart()  
{  
    CArrayShort *array=new CArrayShort;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- resize array  
    if(!array.Resize(10))  
    {  
        printf("Resize error");  
        delete array;  
        return;  
    }  
    ///--- delete array  
    delete array;  
}
```

Shutdown

Clears the array with a full memory release.

```
bool Shutdown()
```

Return Value

true - successful, false - error.

Example:

```
//--- example for CArrayShort::Shutdown()
#include <Arrays\ArrayShort.mqh>
//---
void OnStart()
{
    CArrayShort *array=new CArrayShort;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- . . .
    //--- shutdown array
    if(!array.Shutdown())
    {
        printf("Shutdown error");
        delete array;
        return;
    }
    //--- delete array
    delete array;
}
```

Add

Adds an element to the end of the array.

```
bool Add(  
    short element    // element to add  
)
```

Parameters

element

[in] Value of the element to add to the array.

Return Value

true - successful, false - cannot add an element.

Example:

```
///--- example for CArrayShort::Add(short)  
#include <Arrays\ArrayShort.mqh>  
///---  
void OnStart()  
{  
    CArrayShort *array=new CArrayShort;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    for(int i=0;i<100;i++)  
    {  
        if(!array.Add(i))  
        {  
            printf("Element addition error");  
            delete array;  
            return;  
        }  
    }  
    ///--- use array  
    ///--- . . .  
    ///--- delete array  
    delete array;  
}
```

AddArray

Adds elements of one array to the end of another.

```
bool AddArray(  
    const short& src[]      // source array  
)
```

Parameters

src[]

[in] Reference to an array of source elements to add.

Return Value

true - successful, false - cannot add items.

Example:

```
///--- example for CArrayShort::AddArray(const short &[])  
#include <Arrays\ArrayShort.mqh>  
///---  
short src[];  
///---  
void OnStart()  
{  
    CArrayShort *array=new CArrayShort;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add another array  
    if(!array.AddArray(src))  
    {  
        printf("Array addition error");  
        delete array;  
        return;  
    }  
    ///--- use array  
    ///--- . . .  
    ///--- delete array  
    delete array;  
}
```

AddArray

Adds elements of one array to the end of another.

```
bool AddArray(  
    const CArrayShort* src      // pointer to the source  
)
```

Parameters

src

[in] Pointer to an instance of CArrayShort class used as a source of elements to add.

Return Value

true - successful, false - cannot add items.

Example:

```
///--- example for CArrayShort::AddArray(const CArrayShort*)  
#include <Arrays\ArrayShort.mqh>  
///---  
void OnStart()  
{  
    CArrayShort *array=new CArrayShort;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- create source array  
    CArrayShort *src=new CArrayShort;  
    if(src==NULL)  
    {  
        printf("Object create error");  
        delete array;  
        return;  
    }  
    ///--- add source arrays elements  
    ///--- . . .  
    ///--- add another array  
    if(!array.AddArray(src))  
    {  
        printf("Array addition error");  
        delete src;  
        delete array;  
        return;  
    }  
    ///--- delete source array  
    delete src;
```

```
//--- use array  
//--- . . .  
//--- delete array  
delete array;  
}
```

Insert

Inserts an element to the specified position in the array.

```
bool Insert(  
    short element,    // element to insert  
    int pos           // position  
)
```

Parameters

element

[in] Value of the element to be inserted into the array

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert the element.

Example:

```
//--- example for CArrayShort::Insert(short,int)  
#include <Arrays\ArrayShort.mqh>  
//---  
void OnStart()  
{  
    CArrayShort *array=new CArrayShort;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- insert elements  
    for(int i=0;i<100;i++)  
    {  
        if(!array.Insert(i,0))  
        {  
            printf("Insert error");  
            delete array;  
            return;  
        }  
    }  
    //--- use array  
    //--- . . .  
    //--- delete array  
    delete array;  
}
```

InsertArray

Inserts elements of one array from the specified position of another array.

```
bool  InsertArray(  
    const short&  src[],      // source array  
    int           pos         // position  
)
```

Parameters

src[]

[in] Reference to an array used as a source of elements to insert

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert items.

Example:

```
//--- example for CArrayShort::InsertArray(const short &[],int)  
#include <Arrays\ArrayShort.mqh>  
//---  
short src[];  
//---  
void OnStart()  
{  
    CArrayShort *array=new CArrayShort;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- insert another array  
    if(!array.InsertArray(src,0))  
    {  
        printf("Array inserting error");  
        delete array;  
        return;  
    }  
    //--- use array  
    //--- . . .  
    //--- delete array  
    delete array;  
}
```

InsertArray

Inserts elements of one array from the specified position of another array.

```
bool InsertArray(  
    CArrayShort* src,      // pointer to the source  
    int pos               // position  
)
```

Parameters

src

[in] Pointer to an instance of the CArrayShort class used as a source of elements to insert.

pos

[in] Position in the array to insert.

Return Value

true - successful, false - cannot insert items.

Example:

```
//--- example for CArrayShort::InsertArray(const CArrayShort*,int)  
#include <Arrays\ArrayShort.mqh>  
//---  
void OnStart()  
{  
    CArrayShort *array=new CArrayShort;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- create source array  
    CArrayShort *src=new CArrayShort;  
    if(src==NULL)  
    {  
        printf("Object create error");  
        delete array;  
        return;  
    }  
    //--- add source arrays elements  
    //--- . . .  
    //--- insert another array  
    if(!array.InsertArray(src,0))  
    {  
        printf("Array inserting error");  
        delete src;  
        delete array;  
    }  
}
```

```
        return;  
    }  
    //--- delete source array  
    delete src;  
    //--- use array  
    //--- . . .  
    //--- delete array  
    delete array;  
}
```

AssignArray

Copies the elements of one array to another.

```
bool AssignArray(  
    const short& src[]      // source array  
)
```

Parameters

src[]

[in] Reference to an array used as a source of elements to copy.

Return Value

true - successful, false - cannot copy the items.

Example:

```
///--- example for CArrayShort::AssignArray(const short &[])  
#include <Arrays\ArrayShort.mqh>  
///---  
short src[];  
///---  
void OnStart()  
{  
    CArrayShort *array=new CArrayShort;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- assign another array  
    if(!array.AssignArray(src))  
    {  
        printf("Array assigned error");  
        delete array;  
        return;  
    }  
    ///--- use array  
    ///--- . . .  
    ///--- delete array  
    delete array;  
}
```

AssignArray

Copies the elements of one array to another.

```
bool AssignArray(  
    const CArrayShort* src      // pointer to the source  
)
```

Parameters

src

[in] Pointer to an instance of the CArrayShort class used as a source of elements to copy.

Return Value

true - successful, false - cannot copy the elements.

Example:

```
//--- example for CArrayShort::AssignArray(const CArrayShort*)  
#include <Arrays\ArrayShort.mqh>  
//---  
void OnStart()  
{  
    CArrayShort *array=new CArrayShort;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- create source array  
    CArrayShort *src =new CArrayShort;  
    if(src==NULL)  
    {  
        printf("Object create error");  
        delete array;  
        return;  
    }  
    //--- add source arrays elements  
    //--- . . .  
    //--- assign another array  
    if(!array.AssignArray(src))  
    {  
        printf("Array assigned error");  
        delete src;  
        delete array;  
        return;  
    }  
    //--- arrays is identical  
    //--- delete source array
```

```
delete src;  
//--- use array  
//--- . . .  
//--- delete array  
delete array;  
}
```

Update

Changes the element at the specified array position.

```
bool Update(  
    int    pos,          // position  
    short  element       // value  
)
```

Parameters

pos

[in] Position of the element in the array to change

element

[in] New value of the element

Return Value

true - successful, false - cannot change the element.

Example:

```
//--- example for CArrayShort::Update(int,short)  
#include <Arrays\ArrayShort.mqh>  
//---  
void OnStart()  
{  
    CArrayShort *array=new CArrayShort;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- update element  
    if(!array.Update(0,100))  
    {  
        printf("Update error");  
        delete array;  
        return;  
    }  
    //--- delete array  
    delete array;  
}
```

Shift

Moves an item from a given position in the array to the specified offset.

```
bool Shift(  
    int pos,          // positions  
    int shift         // shift  
)
```

Parameters

pos

[in] Position of the moved element in the array

shift

[in] The shift value (both positive and negative).

Return Value

true - successful, false - cannot move the element.

Example:

```
//--- example for CArrayShort::Shift(int,int)  
#include <Arrays\ArrayShort.mqh>  
//---  
void OnStart()  
{  
    CArrayShort *array=new CArrayShort;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- shift element  
    if(!array.Shift(10,-5))  
    {  
        printf("Shift error");  
        delete array;  
        return;  
    }  
    //--- delete array  
    delete array;  
}
```

Delete

Removes the element from the specified array position.

```
bool Delete(  
    int pos    // position  
)
```

Parameters

pos

[in] Position of the array element to be removed.

Return Value

true - successful, false - cannot remove the element.

Example:

```
//--- example for CArrayShort::Delete(int)  
#include <Arrays\ArrayShort.mqh>  
//---  
void OnStart()  
{  
    CArrayShort *array=new CArrayShort;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- delete element  
    if(!array.Delete(0))  
    {  
        printf("Delete error");  
        delete array;  
        return;  
    }  
    //--- delete array  
    delete array;  
}
```

DeleteRange

Deletes a group of elements from the specified array position.

```
bool DeleteRange(  
    int from,      // position of the first element  
    int to         // position of the last element  
)
```

Parameters

from

[in] Position of the first array element to be removed.

to

[in] Position of the last array element to be removed.

Return Value

true - successful, false - cannot remove the elements.

Example:

```
//--- example for CArrayShort::DeleteRange(int,int)  
#include <Arrays\ArrayShort.mqh>  
//---  
void OnStart()  
{  
    CArrayShort *array=new CArrayShort;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- delete elements  
    if(!array.DeleteRange(0,10))  
    {  
        printf("Delete error");  
        delete array;  
        return;  
    }  
    //--- delete array  
    delete array;  
}
```

At

Gets the element from the specified array position.

```
short At(  
    int pos    // position  
    ) const
```

Parameters

pos

[in] Position of the desired element in the array.

Return Value

The value of the element - success, SHORT_MAX - there was an attempt to get an element from a non-existing position (the last error code is ERR_OUT_OF_RANGE).

Note

Of course, SHORT_MAX may be a valid value of an array element. Therefore, always check the last error code after receiving such a value.

Example:

```
///--- example for CArrayShort::At(int)  
#include <Arrays\ArrayShort.mqh>  
///---  
void OnStart()  
{  
    CArrayShort *array=new CArrayShort;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    for(int i=0;i<array.Total();i++)  
    {  
        short result=array.At(i);  
        if(result==SHORT_MAX && GetLastError()==ERR_OUT_OF_RANGE)  
        {  
            ///--- error of reading from array  
            printf("Get element error");  
            delete array;  
            return;  
        }  
        ///--- use element  
        ///--- . . .  
    }  
}
```

```
//--- delete array  
delete array;  
}
```

CompareArray

Compares the array with another one.

```
bool CompareArray(  
    const short& src[]      // source array  
    ) const
```

Parameters

src[]

[in] Reference to an array used as a source of elements for comparison.

Return Value

true - arrays are equal, false - arrays are not equal.

Example:

```
//--- example for CArrayShort::CompareArray(const short &[])  
#include <Arrays\ArrayShort.mqh>  
//---  
short src[];  
//---  
void OnStart()  
{  
    CArrayShort *array=new CArrayShort;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- compare with another array  
    int result=array.CompareArray(src);  
    //--- delete array  
    delete array;  
}
```

CompareArray

Compares the array with another one.

```
bool CompareArray(  
    const CArrayShort* src      // pointer to the source  
    ) const
```

Parameters

src

[in] Pointer to an instance of the CArrayShort class used as a source of elements for comparison.

Return Value

true - arrays are equal, false - arrays are not equal.

Example:

```
//--- example for CArrayShort::CompareArray(const CArrayShort*)  
#include <Arrays\ArrayShort.mqh>  
//---  
void OnStart()  
{  
    CArrayShort *array=new CArrayShort;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- create source array  
    CArrayShort *src=new CArrayShort;  
    if(src==NULL)  
    {  
        printf("Object create error");  
        delete array;  
        return;  
    }  
    //--- add source arrays elements  
    //--- . . .  
    //--- compare with another array  
    int result=array.CompareArray(src);  
    //--- delete arrays  
    delete src;  
    delete array;  
}
```

InsertSort

Inserts an element in a sorted array.

```
bool InsertSort(  
    short element    // element to insert  
)
```

Parameters

element

[in] Value of the element to be inserted into a sorted array

Return Value

true - successful, false - cannot insert the element.

Example:

```
///--- example for CArrayShort::InsertSort(short)  
#include <Arrays\ArrayShort.mqh>  
///---  
void OnStart()  
{  
    CArrayShort *array=new CArrayShort;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- sort array  
    array.Sort();  
    ///--- insert element  
    if(!array.InsertSort(100))  
    {  
        printf("Insert error");  
        delete array;  
        return;  
    }  
    ///--- delete array  
    delete array;  
}
```

Search

Searches for an element equal to the sample in the sorted array.

```
int Search(  
    short element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayShort::Search(short)  
#include <Arrays\ArrayShort.mqh>  
//---  
void OnStart()  
{  
    CArrayShort *array=new CArrayShort;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.Search(100)!=-1) printf("Element found");  
    else                     printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchGreat

Searches for an element with a value exceeding the value of the sample in the sorted array.

```
int SearchGreat(  
    short element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - element not found.

Example:

```
//--- example for CArrayShort::SearchGreat(short)  
#include <Arrays\ArrayShort.mqh>  
//---  
void OnStart()  
{  
    CArrayShort *array=new CArrayShort;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.SearchGreat(100)!=-1) printf("Element found");  
    else                          printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchLess

Searches for an element with a value less than the value of the sample in the sorted array.

```
int SearchLess(  
    short element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
///--- example for CArrayShort::SearchLess(short)  
#include <Arrays\ArrayShort.mqh>  
///---  
void OnStart()  
{  
    CArrayShort *array=new CArrayShort;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- sort array  
    array.Sort();  
    ///--- search element  
    if(array.SearchLess(100)!=-1) printf("Element found");  
    else                          printf("Element not found");  
    ///--- delete array  
    delete array;  
}
```

SearchGreatOrEqual

Searches for an element with a value greater than or equal to the value of the sample in the sorted array.

```
int SearchGreatOrEqual(  
    short element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
///--- example for CArrayShort::SearchGreatOrEqual(short)  
#include <Arrays\ArrayShort.mqh>  
///---  
void OnStart()  
{  
    CArrayShort *array=new CArrayShort;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- sort array  
    array.Sort();  
    ///--- search element  
    if(array.SearchGreatOrEqual(100)!=-1) printf("Element found");  
    else                                printf("Element not found");  
    ///--- delete array  
    delete array;  
}
```

SearchLessOrEqual

Searches for an element with a value less than or equal to the value of the sample in the sorted array.

```
int SearchLessOrEqual(  
    short element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayShort::SearchLessOrEqual(short)  
#include <Arrays\ArrayShort.mqh>  
//---  
void OnStart()  
{  
    CArrayShort *array=new CArrayShort;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.SearchLessOrEqual(100) != -1) printf("Element found");  
    else                                printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchFirst

Searches for the first element equal to the sample in the sorted array.

```
int SearchFirst(  
    short element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayShort::SearchFirst(short)  
#include <Arrays\ArrayShort.mqh>  
//---  
void OnStart()  
{  
    CArrayShort *array=new CArrayShort;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.SearchFirst(100)!=-1) printf("Element found");  
    else                          printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchLast

Searches for the last element equal to the sample in the sorted array.

```
int SearchLast(  
    short element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayShort::SearchLast(short)  
#include <Arrays\ArrayShort.mqh>  
//---  
void OnStart()  
{  
    CArrayShort *array=new CArrayShort;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.SearchLast(100)!=-1) printf("Element found");  
    else                          printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchLinear

Searches for the element equal to the sample in the array.

```
int SearchLinear(  
    short element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Note

The method uses the linear search (or sequential search) algorithm for unsorted arrays.

Example:

```
///--- example for CArrayShort::SearchLinear(short)  
#include <Arrays\ArrayShort.mqh>  
///---  
void OnStart()  
{  
    CArrayShort *array=new CArrayShort;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- search element  
    if(array.SearchLinear(100) != -1) printf("Element found");  
    else                             printf("Element not found");  
    ///--- delete array  
    delete array;  
}
```

Save

Saves data array in the file.

```
virtual bool Save(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CArrayShort::Save(int)  
#include <Arrays\ArrayShort.mqh>  
//---  
void OnStart()  
{  
    int file_handle;  
    CArrayShort *array=new CArrayShort;  
    //---  
    if(array!=NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add 100 arrays elements  
    for(int i=0;i<100;i++)  
    {  
        array.Add(i);  
    }  
    //--- open file  
    file_handle=FileOpen("MyFile.bin",FILE_WRITE|FILE_BIN|FILE_ANSI);  
    if(file_handle>=0)  
    {  
        if(!array.Save(file_handle))  
        {  
            //--- file save error  
            printf("File save: Error %d!",GetLastError());  
            delete array;  
            FileClose(file_handle);  
            //---  
            return;  
        }  
        FileClose(file_handle);  
    }
```

```
    }  
    delete array;  
}
```

Load

Loads data array from the file.

```
virtual bool Load(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CArrayShort::Load(int)  
#include <Arrays\ArrayShort.mqh>  
//---  
void OnStart()  
{  
    int file_handle;  
    CArrayShort *array=new CArrayShort;  
    //---  
    if(array!=NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- open file  
    file_handle=FileOpen("MyFile.bin",FILE_READ|FILE_BIN|FILE_ANSI);  
    if(file_handle>=0)  
    {  
        if(!array.Load(file_handle))  
        {  
            //--- file load error  
            printf("File load: Error %d!",GetLastError());  
            delete array;  
            FileClose(file_handle);  
            //---  
            return;  
        }  
        FileClose(file_handle);  
    }  
    //--- use arrays elements  
    for(int i=0;i<array.Total();i++)  
    {  
        printf("Element[%d] = %d",i,array.At(i));  
    }  
}
```

```
    }  
    delete array;  
}
```

Type

Gets the array type identifier.

```
virtual int Type() const
```

Return Value

Array type identifier (for CArrayShort - 82).

Example:

```
//--- example for CArrayShort::Type()
#include <Arrays\ArrayShort.mqh>
//---
void OnStart()
{
    CArrayShort *array=new CArrayShort;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- get array type
    int type=array.Type();
    //--- delete array
    delete array;
}
```

CArrayInt

CArrayInt is a class of dynamic array of int or uint variables.

Description

The class CArrayInt provides the ability to work with a dynamic array of int or uint variables. The class allows adding/inserting/deleting array elements, performing an array sorting, and searching in a sorted array. In addition, methods of working with files have been implemented.

Declaration

```
class CArrayInt : public CArray
```

Title

```
#include <Arrays\ArrayInt.mqh>
```

Class Methods by Groups

Memory control	
Reserve	Allocates memory to increase the size of the array
Resize	Sets a new (smaller) size of the array
Shutdown	Clears the array with a full memory release
Add methods	
Add	Adds an element to the end of the array
AddArray	Adds elements of one array to the end of another
AddArray	Adds elements of one array to the end of another
Insert	Inserts an element to the specified position in the array
InsertArray	Inserts to an array elements from another array from the specified position

InsertArray	Inserts to an array elements from another array from the specified position
AssignArray	Copies the elements of one array to another
AssignArray	Copies the elements of one array to another
Update methods	
Update	Changes the element at the specified array position
Shift	Moves an element from a given position in the array to the specified offset
Delete methods	
Delete	Removes the element from the specified array position
DeleteRange	Deletes a group of elements from the specified array position
Access methods	
At	Gets the element from the specified array position
Compare methods	
CompareArray	Compares the array with another one
CompareArray	Compares the array with another one
Sorted array operations	
InsertSort	Inserts an element in a sorted array
Search	Searches for an element equal to the sample in the sorted array
SearchGreat	Searches for an element with a value exceeding the value of the sample in the sorted array
SearchLess	Searches for an element with a value less than the value of the sample in the sorted array
SearchGreatOrEqual	Searches for an element with a value greater than or equal to the value of the sample in the sorted array
SearchLessOrEqual	Searches for an element with a value less than or equal to the value of the sample in the sorted array
SearchFirst	Searches for the first element equal to the sample in the sorted array

SearchLast	Searches for the last element equal to the sample in the sorted array
SearchLinear	Searches for the element equal to the sample in the array
Input/output	
virtual Save	Saves data array in the file
virtual Load	Loads data array from the file
virtual Type	Gets the type identifier of the array

Methods inherited from class CObject

Prev, Prev, Next, Next, [Compare](#)

Methods inherited from class CArray

[Step](#), [Step](#), [Total](#), [Available](#), [Max](#), [IsSorted](#), [SortMode](#), [Clear](#), [Sort](#)

Reserve

Allocates memory to increase the size of the array.

```
bool Reserve (
    int size      // number
)
```

Parameters

size

[in] The number of additional elements of the array.

Return Value

true - successful, false - there was an attempt to request for an amount less than or equal to zero, or failed to increase the array.

Note

To reduce fragmentation of memory, the array size is changed using the step previously determined by the Step(int) method or the default step of 16.

Example:

```
///--- example for CArrayInt::Reserve(int)
#include <Arrays\ArrayInt.mqh>
///---
void OnStart()
{
    CArrayInt *array=new CArrayInt;
    ///---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    ///--- reserve memory
    if(!array.Reserve(1024))
    {
        printf("Reserve error");
        delete array;
        return;
    }
    ///--- use array
    ///--- . . .
    ///--- delete array
    delete array;
}
```

Resize

Sets a new (smaller) size of the array.

```
bool Resize(  
    int size      // number  
)
```

Parameters

size

[in] New size of the array.

Return Value

true - successful, false - there was an attempt to set the size less than or equal to zero.

Note

Changing the size of the array allows using the memory optimally. Excessive elements on the right are lost. To reduce fragmentation of memory, the array size is changed by the step previously determined by the Step(int) method or the default step of 16.

Example:

```
///--- example for CArrayInt::Resize(int)  
#include <Arrays\ArrayInt.mqh>  
///---  
void OnStart()  
{  
    CArrayInt *array=new CArrayInt;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- resize array  
    if(!array.Resize(10))  
    {  
        printf("Resize error");  
        delete array;  
        return;  
    }  
    ///--- delete array  
    delete array;  
}
```

Shutdown

Clears the array with a full memory release.

```
bool Shutdown()
```

Return Value

true - successful, false - error.

Example:

```
//--- example for CArrayInt::Shutdown()
#include <Arrays\ArrayInt.mqh>
//---
void OnStart()
{
    CArrayInt *array=new CArrayInt;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- . . .
    //--- shutdown array
    if(!array.Shutdown())
    {
        printf("Shutdown error");
        delete array;
        return;
    }
    //--- delete array
    delete array;
}
```

Add

Adds an element to the end of the array.

```
bool Add(  
    int element    // element to add  
)
```

Parameters

element

[in] Value of the element to add to the array.

Return Value

true - successful, false - cannot add an element.

Example:

```
///--- example for CArrayInt::Add(int)  
#include <Arrays\ArrayInt.mqh>  
///---  
void OnStart()  
{  
    CArrayInt *array=new CArrayInt;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    for(int i=0;i<100;i++)  
    {  
        if(!array.Add(i))  
        {  
            printf("Element addition error");  
            delete array;  
            return;  
        }  
    }  
    ///--- use array  
    ///--- . . .  
    ///--- delete array  
    delete array;  
}
```

AddArray

Adds elements of one array to the end of another.

```
bool AddArray(  
    const int& src[]      // source array  
)
```

Parameters

src[]

[in] Reference to an array of source elements to add.

Return Value

true - successful, false - cannot add items.

Example:

```
//--- example for CArrayInt::AddArray(const int &[])  
#include <Arrays\ArrayInt.mqh>  
//---  
int src[];  
//---  
void OnStart()  
{  
    CArrayInt *array=new CArrayInt;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add another array  
    if(!array.AddArray(src))  
    {  
        printf("Array addition error");  
        delete array;  
        return;  
    }  
    //--- use array  
    //--- . . .  
    //--- delete array  
    delete array;  
}
```

AddArray

Adds elements of one array to the end of another.

```
bool AddArray(  
    const CArrayInt* src      // pointer to the source  
)
```

Parameters

src

[in] Pointer to an instance of CArrayInt class used as a source of elements to add.

Return Value

true - successful, false - cannot add items.

Example:

```
//--- example for CArrayInt::AddArray(const CArrayInt*)  
#include <Arrays\ArrayInt.mqh>  
//---  
void OnStart()  
{  
    CArrayInt *array=new CArrayInt;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- create source array  
    CArrayInt *src=new CArrayInt;  
    if(src==NULL)  
    {  
        printf("Object create error");  
        delete array;  
        return;  
    }  
    //--- add source arrays elements  
    //--- . . .  
    //--- add another array  
    if(!array.AddArray(src))  
    {  
        printf("Array addition error");  
        delete src;  
        delete array;  
        return;  
    }  
    //--- delete source array  
    delete src;
```

```
//--- use array  
//--- . . .  
//--- delete array  
delete array;  
}
```

Insert

Inserts an element to the specified position in the array.

```
bool Insert(  
    int element,    // element to insert  
    int pos         // position  
)
```

Parameters

element

[in] Value of the element to be inserted into the array

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert the element.

Example:

```
//--- example for CArrayInt::Insert(int,int)  
#include <Arrays\ArrayInt.mqh>  
//---  
void OnStart()  
{  
    CArrayInt *array=new CArrayInt;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- insert elements  
    for(int i=0;i<100;i++)  
    {  
        if(!array.Insert(i,0))  
        {  
            printf("Insert error");  
            delete array;  
            return;  
        }  
    }  
    //--- use array  
    //--- . . .  
    //--- delete array  
    delete array;  
}
```

InsertArray

Inserts elements of one array from the specified position of another array.

```
bool  InsertArray(  
    const int&  src[],      // source array  
    int         pos        // position  
)
```

Parameters

src[]

[in] Reference to an array used as a source of elements to insert

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert items.

Example:

```
//--- example for CArrayInt::InsertArray(const int &[],int)  
#include <Arrays\ArrayInt.mqh>  
//---  
int src[];  
//---  
void OnStart()  
{  
    CArrayInt *array=new CArrayInt;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- insert another array  
    if(!array.InsertArray(src,0))  
    {  
        printf("Array inserting error");  
        delete array;  
        return;  
    }  
    //--- use array  
    //--- . . .  
    //--- delete array  
    delete array;  
}
```

InsertArray

Inserts elements of one array from the specified position of another array.

```
bool InsertArray(  
    CArrayInt* src,      // pointer to the source  
    int pos             // position  
)
```

Parameters

src

[in] Pointer to an instance of the CArrayInt class used as a source of elements to insert.

pos

[in] Position in the array to insert.

Return Value

true - successful, false - cannot insert items.

Example:

```
//--- example for CArrayInt::InsertArray(const CArrayInt*,int)  
#include <Arrays\ArrayInt.mqh>  
//---  
void OnStart()  
{  
    CArrayInt *array=new CArrayInt;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- create source array  
    CArrayInt *src=new CArrayInt;  
    if(src==NULL)  
    {  
        printf("Object create error");  
        delete array;  
        return;  
    }  
    //--- add source arrays elements  
    //--- . . .  
    //--- insert another array  
    if(!array.InsertArray(src,0))  
    {  
        printf("Array inserting error");  
        delete src;  
        delete array;  
    }  
}
```

```
        return;  
    }  
    //-- delete source array  
    delete src;  
    //-- use array  
    //-- . . .  
    //-- delete array  
    delete array;  
}
```

AssignArray

Copies the elements of one array to another.

```
bool AssignArray(  
    const int& src[]    // source array  
)
```

Parameters

src[]

[in] Reference to an array used as a source of elements to copy.

Return Value

true - successful, false - cannot copy the items.

Example:

```
///--- example for CArrayInt::AssignArray(const int &[])  
#include <Arrays\ArrayInt.mqh>  
///---  
int src[];  
///---  
void OnStart()  
{  
    CArrayInt *array=new CArrayInt;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- assign another array  
    if(!array.AssignArray(src))  
    {  
        printf("Array assigned error");  
        delete array;  
        return;  
    }  
    ///--- use array  
    ///--- . . .  
    ///--- delete array  
    delete array;  
}
```

AssignArray

Copies the elements of one array to another.

```
bool AssignArray(  
    const CArrayInt* src      // pointer to the source  
)
```

Parameters

src

[in] Pointer to an instance of the CArrayInt class used as a source of elements to copy.

Return Value

true - successful, false - cannot copy the elements.

Example:

```
///--- example for CArrayInt::AssignArray(const CArrayInt*)  
#include <Arrays\ArrayInt.mqh>  
///---  
void OnStart()  
{  
    CArrayInt *array=new CArrayInt;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- create source array  
    CArrayInt *src =new CArrayInt;  
    if(src==NULL)  
    {  
        printf("Object create error");  
        delete array;  
        return;  
    }  
    ///--- add source arrays elements  
    ///--- . . .  
    ///--- assign another array  
    if(!array.AssignArray(src))  
    {  
        printf("Array assigned error");  
        delete src;  
        delete array;  
        return;  
    }  
}
```

```
//--- arrays is identical
//--- delete source array
delete src;
//--- use array
//--- . . .
//--- delete array
delete array;
}
```

Update

Changes the element at the specified array position.

```
bool Update(  
    int pos,           // position  
    int element        // value  
)
```

Parameters

pos

[in] Position of the element in the array to change.

element

[in] New value of the element

Return Value

true - successful, false - cannot change the element.

Example:

```
//--- example for CArrayInt::Update(int,int)  
#include <Arrays\ArrayInt.mqh>  
//---  
void OnStart()  
{  
    CArrayInt *array=new CArrayInt;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- update element  
    if(!array.Update(0,10000))  
    {  
        printf("Update error");  
        delete array;  
        return;  
    }  
    //--- delete array  
    delete array;  
}
```

Shift

Moves an item from a given position in the array to the specified offset.

```
bool Shift(  
    int pos,          // position  
    int shift         // shift  
)
```

Parameters

pos

[in] Position of the moved element in the array

shift

[in] The shift value (both positive and negative).

Return Value

true - successful, false - cannot move the element.

Example:

```
//--- example for CArrayInt::Shift(int,int)  
#include <Arrays\ArrayInt.mqh>  
//---  
void OnStart()  
{  
    CArrayInt *array=new CArrayInt;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- shift element  
    if(!array.Shift(10,-5))  
    {  
        printf("Shift error");  
        delete array;  
        return;  
    }  
    //--- delete array  
    delete array;  
}
```

Delete

Removes the element from the specified array position.

```
bool Delete(  
    int pos    // position  
)
```

Parameters

pos

[in] Position of the array element to be removed.

Return Value

true - successful, false - cannot remove the element.

Example:

```
///--- example for CArrayInt::Delete(int)  
#include <Arrays\ArrayInt.mqh>  
///---  
void OnStart()  
{  
    CArrayInt *array=new CArrayInt;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- delete element  
    if(!array.Delete(0))  
    {  
        printf("Delete error");  
        delete array;  
        return;  
    }  
    ///--- delete array  
    delete array;  
}
```

DeleteRange

Deletes a group of elements from the specified array position.

```
bool DeleteRange(  
    int from,      // position of the first element  
    int to         // position of the last element  
)
```

Parameters

from

[in] Position of the first array element to be removed.

to

[in] Position of the last array element to be removed.

Return Value

true - successful, false - cannot remove the elements.

Example:

```
//--- example for CArrayInt::DeleteRange(int,int)  
#include <Arrays\ArrayInt.mqh>  
//---  
void OnStart()  
{  
    CArrayInt *array=new CArrayInt;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- delete elements  
    if(!array.DeleteRange(0,10))  
    {  
        printf("Delete error");  
        delete array;  
        return;  
    }  
    //--- delete array  
    delete array;  
}
```

At

Gets the element from the specified array position.

```
int At(  
    int pos    // position  
) const
```

Parameters

pos

[in] Position of the desired element in the array.

Return Value

The value of the element - success, INT_MAX - there was an attempt to get an element from a non-existing position (the last error code is ERR_OUT_OF_RANGE).

Note

Of course, INT_MAX may be a valid value of an array element. Therefore, always check the last error code after receiving such a value.

Example:

```
///--- example for CArrayInt::At(int)  
#include <Arrays\ArrayInt.mqh>  
///---  
void OnStart()  
{  
    CArrayInt *array=new CArrayInt;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    for(int i=0;i<array.Total();i++)  
    {  
        int result=array.At(i);  
        if(result==INT_MAX && GetLastError()==ERR_OUT_OF_RANGE)  
        {  
            ///--- error of reading from array  
            printf("Get element error");  
            delete array;  
            return;  
        }  
        ///--- use element  
        ///--- . . .  
    }  
}
```

```
//--- delete array  
delete array;  
}
```

CompareArray

Compares the array with another one.

```
bool CompareArray(  
    const int& src[]    // source array  
    ) const
```

Parameters

src[]

[in] Reference to an array used as a source of elements for comparison.

Return Value

true - arrays are equal, false - arrays are not equal.

Example:

```
///--- example for CArrayInt::CompareArray(const int &[])  
#include <Arrays\ArrayInt.mqh>  
///---  
int src[];  
///---  
void OnStart()  
{  
    CArrayInt *array=new CArrayInt;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- compare with another array  
    int result=array.CompareArray(src);  
    ///--- delete array  
    delete array;  
}
```

CompareArray

Compares the array with another one.

```
bool CompareArray(  
    const CArrayInt* src      // pointer to the source  
    ) const
```

Parameters

src

[in] Pointer to an instance of the CArrayInt class used as a source of elements for comparison.

Return Value

true - arrays are equal, false - arrays are not equal.

Example:

```
///--- example for CArrayInt::CompareArray(const CArrayInt*)  
#include <Arrays\ArrayInt.mqh>  
///---  
void OnStart()  
{  
    CArrayInt *array=new CArrayInt;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- create source array  
    CArrayInt *src=new CArrayInt;  
    if(src==NULL)  
    {  
        printf("Object create error");  
        delete array;  
        return;  
    }  
    ///--- add source arrays elements  
    ///--- . . .  
    ///--- compare with another array  
    int result=array.CompareArray(src);  
    ///--- delete arrays  
    delete src;  
    delete array;  
}
```

InsertSort

Inserts an element in a sorted array.

```
bool InsertSort(  
    int element    // element to insert  
)
```

Parameters

element

[in] Value of the element to be inserted into a sorted array

Return Value

true - successful, false - cannot insert the element.

Example:

```
///--- example for CArrayInt::InsertSort(int)  
#include <Arrays\ArrayInt.mqh>  
///---  
void OnStart()  
{  
    CArrayInt *array=new CArrayInt;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- sort array  
    array.Sort();  
    ///--- insert element  
    if(!array.InsertSort(10000))  
    {  
        printf("Insert error");  
        delete array;  
        return;  
    }  
    ///--- delete array  
    delete array;  
}
```

Search

Searches for an element equal to the sample in the sorted array.

```
int Search(  
    int element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayInt::Search(int)  
#include <Arrays\ArrayInt.mqh>  
//---  
void OnStart()  
{  
    CArrayInt *array=new CArrayInt;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.Search(10000) != -1) printf("Element found");  
    else                          printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchGreat

Searches for an element with a value exceeding the value of the sample in the sorted array.

```
int SearchGreat(  
    int element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayInt::SearchGreat(int)  
#include <Arrays\ArrayInt.mqh>  
//---  
void OnStart()  
{  
    CArrayInt *array=new CArrayInt;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.SearchGreat(10000) != -1) printf("Element found");  
    else                             printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchLess

Searches for an element with a value less than the value of the sample in the sorted array.

```
int SearchLess(  
    int element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayInt::SearchLess(int)  
#include <Arrays\ArrayInt.mqh>  
//---  
void OnStart()  
{  
    CArrayInt *array=new CArrayInt;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.SearchLess(10000) != -1) printf("Element found");  
    else                             printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchGreatOrEqual

Searches for an element with a value greater than or equal to the value of the sample in the sorted array.

```
int SearchGreatOrEqual(  
    int element    // sample  
) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
///--- example for CArrayInt::SearchGreatOrEqual(int)  
#include <Arrays\ArrayInt.mqh>  
///---  
void OnStart()  
{  
    CArrayInt *array=new CArrayInt;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- sort array  
    array.Sort();  
    ///--- search element  
    if(array.SearchGreatOrEqual(10000)!=-1) printf("Element found");  
    else                                  printf("Element not found");  
    ///--- delete array  
    delete array;  
}
```

SearchLessOrEqual

Searches for an element with a value less than or equal to the value of the sample in the sorted array.

```
int SearchLessOrEqual(  
    int element    // sample  
) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayInt::SearchLessOrEqual(int)  
#include <Arrays\ArrayInt.mqh>  
//---  
void OnStart()  
{  
    CArrayInt *array=new CArrayInt;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.SearchLessOrEqual(10000)!=-1) printf("Element found");  
    else                                printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchFirst

Searches for the first element equal to the sample in the sorted array.

```
int SearchFirst(  
    int element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayInt:: SearchFirst(int)  
#include <Arrays\ArrayInt.mqh>  
//---  
void OnStart()  
{  
    CArrayInt *array=new CArrayInt;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.SearchFirst(10000)!=-1) printf("Element found");  
    else                             printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchLast

Searches for the last element equal to the sample in the sorted array.

```
int SearchLast(  
    int element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayInt::SearchLast(int)  
#include <Arrays\ArrayInt.mqh>  
//---  
void OnStart()  
{  
    CArrayInt *array=new CArrayInt;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.SearchLast(10000) != -1) printf("Element found");  
    else                             printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchLinear

Searches for the element equal to the sample in the array.

```
int SearchLinear(  
    int element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Note

The method uses the linear search (or sequential search) algorithm for unsorted arrays.

Example:

```
///--- example for CArrayInt::SearchLinear(int)  
#include <Arrays\ArrayInt.mqh>  
///---  
void OnStart()  
{  
    CArrayInt *array=new CArrayInt;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- search element  
    if(array.SearchLinear(10000) != -1) printf("Element found");  
    else                               printf("Element not found");  
    ///--- delete array  
    delete array;  
}
```

Save

Saves data array in the file.

```
virtual bool Save(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CArrayInt::Save(int)  
#include <Arrays\ArrayInt.mqh>  
//---  
void OnStart()  
{  
    int file_handle;  
    CArrayInt *array=new CArrayInt;  
    //---  
    if(array!=NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add 100 arrays elements  
    for(int i=0;i<100;i++)  
    {  
        array.Add(i);  
    }  
    //--- open file  
    file_handle=FileOpen("MyFile.bin",FILE_WRITE|FILE_BIN|FILE_ANSI);  
    if(file_handle>=0)  
    {  
        if(!array.Save(file_handle))  
        {  
            //--- file save error  
            printf("File save: Error %d!",GetLastError());  
            delete array;  
            FileClose(file_handle);  
            //---  
            return;  
        }  
        FileClose(file_handle);  
    }
```

```
    }  
    delete array;  
}
```

Load

Loads data array from the file.

```
virtual bool Load(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CArrayInt::Load(int)  
#include <Arrays\ArrayInt.mqh>  
//---  
void OnStart()  
{  
    int file_handle;  
    CArrayInt *array=new CArrayInt;  
    //---  
    if(array!=NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- open file  
    file_handle=FileOpen("MyFile.bin",FILE_READ|FILE_BIN|FILE_ANSI);  
    if(file_handle>=0)  
    {  
        if(!array.Load(file_handle))  
        {  
            //--- file load error  
            printf("File load: Error %d!",GetLastError());  
            delete array;  
            FileClose(file_handle);  
            //---  
            return;  
        }  
        FileClose(file_handle);  
    }  
    //--- use arrays elements  
    for(int i=0;i<array.Total();i++)  
    {  
        printf("Element[%d] = %d",i,array.At(i));  
    }  
}
```

```
    }  
    delete array;  
}
```

Type

Gets the array type identifier.

```
virtual int Type() const
```

Return Value

Array type identifier (for CArrayInt - 82).

Example:

```
//--- example for CArrayInt::Type()
#include <Arrays\ArrayInt.mqh>
//---
void OnStart()
{
    CArrayInt *array=new CArrayInt;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- get array type
    int type=array.Type();
    //--- delete array
    delete array;
}
```

CArrayLong

CArrayLong class is a class of dynamic array of long or ulong variables.

Description

The CArrayLong class provides the ability to work with a dynamic array of long or ulong variables. The class allows adding/inserting/deleting array elements, performing an array sorting, and searching in a sorted array. In addition, methods of working with files have been implemented.

Declaration

```
class CArrayLong : public CArray
```

Title

```
#include <Arrays\ArrayLong.mqh>
```

Inheritance hierarchy

Class Methods by Groups

Memory control	
Reserve	Allocates memory to increase the size of the array
Resize	Sets a new (smaller) size of the array
Shutdown	Clears the array with a full memory release
Add methods	
Add	Adds an element to the end of the array
AddArray	Adds elements of one array to the end of another
AddArray	Adds elements of one array to the end of another
Insert	Inserts an element to the specified position in the array
InsertArray	Inserts to an array elements from another array from the specified position

InsertArray	Inserts to an array elements from another array from the specified position
AssignArray	Copies the elements of one array to another
AssignArray	Copies the elements of one array to another
Update methods	
Update	Changes the element at the specified array position
Shift	Moves an element from a given position in the array to the specified offset
Delete methods	
Delete	Removes the element from the specified array position
DeleteRange	Deletes a group of elements from the specified array position
Access methods	
At	Gets the element from the specified array position
Compare methods	
CompareArray	Compares the array with another one
CompareArray	Compares the array with another one
Sorted array operations	
InsertSort	Inserts an element in a sorted array
Search	Searches for an element equal to the sample in the sorted array
SearchGreat	Searches for an element with a value exceeding the value of the sample in the sorted array
SearchLess	Searches for an element with a value less than the value of the sample in the sorted array
SearchGreatOrEqual	Searches for an element with a value greater than or equal to the value of the sample in the sorted array
SearchLessOrEqual	Searches for an element with a value less than or equal to the value of the sample in the sorted array
SearchFirst	Searches for the first element equal to the sample in the sorted array

SearchLast	Searches for the last element equal to the sample in the sorted array
SearchLinear	Searches for the element equal to the sample in the array
Input/output	
virtual Save	Saves data array in the file
virtual Load	Loads data array from the file
virtual Type	Gets the type identifier of the array

Methods inherited from class CObject

Prev, Prev, Next, Next, [Compare](#)

Methods inherited from class CArray

[Step](#), [Step](#), [Total](#), [Available](#), [Max](#), [IsSorted](#), [SortMode](#), [Clear](#), [Sort](#)

Reserve

Allocates memory to increase the size of the array.

```
bool Reserve (
    int size      // number
)
```

Parameters

size

[in] The number of additional elements of the array.

Return Value

true - successful, false - there was an attempt to request for an amount less than or equal to zero, or failed to increase the array.

Note

To reduce fragmentation of memory, the array size is changed using the step previously determined by the Step(int) method or the default step of 16.

Example:

```
///--- example for CArrayLong::Reserve(int)
#include <Arrays\ArrayLong.mqh>
///---
void OnStart()
{
    CArrayLong *array=new CArrayLong;
    ///---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    ///--- reserve memory
    if(!array.Reserve(1024))
    {
        printf("Reserve error");
        delete array;
        return;
    }
    ///--- use array
    ///--- . . .
    ///--- delete array
    delete array;
}
```

Resize

Sets a new (smaller) size of the array.

```
bool Resize(  
    int size    // size  
)
```

Parameters

size

[in] New size of the array.

Return Value

true - successful, false - there was an attempt to set the size less than or equal to zero.

Note

Changing the size of the array allows using the memory optimally. Excessive elements on the right are lost. To reduce fragmentation of memory, the array size is changed by the step previously determined by the Step(int) method or the default step of 16.

Example:

```
///--- example for CArrayLong::Resize(int)  
#include <Arrays\ArrayLong.mqh>  
///---  
void OnStart()  
{  
    CArrayLong *array=new CArrayLong;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- resize array  
    if(!array.Resize(10))  
    {  
        printf("Resize error");  
        delete array;  
        return;  
    }  
    ///--- delete array  
    delete array;  
}
```

Shutdown

Clears the array with a full memory release.

```
bool Shutdown()
```

Return Value

true - successful, false - error.

Example:

```
//--- example for CArrayLong::Shutdown()
#include <Arrays\ArrayLong.mqh>
//---
void OnStart()
{
    CArrayLong *array=new CArrayLong;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- . . .
    //--- shutdown array
    if(!array.Shutdown())
    {
        printf("Shutdown error");
        delete array;
        return;
    }
    //--- delete array
    delete array;
}
```

Add

Adds an element to the end of the array.

```
bool Add(  
    long element    // element to add  
)
```

Parameters

element

[in] Value of the element to add to the array.

Return Value

true - successful, false - cannot add an element.

Example:

```
///--- example for CArrayLong::Add(long)  
#include <Arrays\ArrayLong.mqh>  
///---  
void OnStart()  
{  
    CArrayLong *array=new CArrayLong;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    for(int i=0;i<100;i++)  
    {  
        if(!array.Add(i))  
        {  
            printf("Element addition error");  
            delete array;  
            return;  
        }  
    }  
    ///--- use array  
    ///--- . . .  
    ///--- delete array  
    delete array;  
}
```

AddArray

Adds elements of one array to the end of another.

```
bool AddArray(  
    const long& src[]      // source array  
)
```

Parameters

src[]

[in] Reference to an array of source elements to add.

Return Value

true - successful, false - cannot add items.

Example:

```
//--- example for CArrayLong::AddArray(const long &[])  
#include <Arrays\ArrayLong.mqh>  
//---  
long src[];  
//---  
void OnStart()  
{  
    CArrayLong *array=new CArrayLong;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add another array  
    if(!array.AddArray(src))  
    {  
        printf("Array addition error");  
        delete array;  
        return;  
    }  
    //--- use array  
    //--- . . .  
    //--- delete array  
    delete array;  
}
```

AddArray

Adds elements of one array to the end of another.

```
bool AddArray(  
    const CArrayLong* src      // pointer to the source  
)
```

Parameters

src

[in] Pointer to an instance of CArrayLong class used as a source of elements to add.

Return Value

true - successful, false - cannot add items.

Example:

```
///--- example for CArrayLong::AddArray(const CArrayLong*)  
#include <Arrays\ArrayLong.mqh>  
///---  
void OnStart()  
{  
    CArrayLong *array=new CArrayLong;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- create source array  
    CArrayLong *src=new CArrayLong;  
    if(src==NULL)  
    {  
        printf("Object create error");  
        delete array;  
        return;  
    }  
    ///--- add source arrays elements  
    ///--- . . .  
    ///--- add another array  
    if(!array.AddArray(src))  
    {  
        printf("Array addition error");  
        delete src;  
        delete array;  
        return;  
    }  
    ///--- delete source array  
    delete src;
```

```
//--- use array  
//--- . . .  
//--- delete array  
delete array;  
}
```

Insert

Inserts an element to the specified position in the array.

```
bool Insert(  
    long element,    // element to insert  
    int pos          // position  
)
```

Parameters

element

[in] Value of the element to be inserted into the array

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert the element.

Example:

```
//--- example for CArrayLong::Insert(long,int)  
#include <Arrays\ArrayLong.mqh>  
//---  
void OnStart()  
{  
    CArrayLong *array=new CArrayLong;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- insert elements  
    for(int i=0;i<100;i++)  
    {  
        if(!array.Insert(i,0))  
        {  
            printf("Insert error");  
            delete array;  
            return;  
        }  
    }  
    //--- use array  
    //--- . . .  
    //--- delete array  
    delete array;  
}
```

InsertArray

Inserts elements of one array from the specified position of another array.

```
bool  InsertArray(  
    const long&  src[],      // source array  
    int          pos         // position  
)
```

Parameters

src[]

[in] Reference to an array used as a source of elements to insert

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert items.

Example:

```
//--- example for CArrayLong::InsertArray(const long &[],int)  
#include <Arrays\ArrayLong.mqh>  
//---  
long src[];  
//---  
void OnStart()  
{  
    CArrayLong *array=new CArrayLong;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- insert another array  
    if(!array.InsertArray(src,0))  
    {  
        printf("Array inserting error");  
        delete array;  
        return;  
    }  
    //--- use array  
    //--- . . .  
    //--- delete array  
    delete array;  
}
```

InsertArray

Inserts elements of one array from the specified position of another array.

```
bool InsertArray(  
    CArrayLong* src,      // pointer to the source  
    int pos              // position  
)
```

Parameters

src

[in] Pointer to an instance of the CArrayLong class used as a source of elements to insert.

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert items.

Example:

```
//--- example for CArrayLong::InsertArray(const CArrayLong*,int)  
#include <Arrays\ArrayLong.mqh>  
//---  
void OnStart()  
{  
    CArrayLong *array=new CArrayLong;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- create source array  
    CArrayLong *src=new CArrayLong;  
    if(src==NULL)  
    {  
        printf("Object create error");  
        delete array;  
        return;  
    }  
    //--- add source arrays elements  
    //--- . . .  
    //--- insert another array  
    if(!array.InsertArray(src,0))  
    {  
        printf("Array inserting error");  
        delete src;  
        delete array;  
    }  
}
```

```
        return;  
    }  
    //-- delete source array  
    delete src;  
    //-- use array  
    //-- . . .  
    //-- delete array  
    delete array;  
}
```

AssignArray

Copies the elements of one array to another.

```
bool AssignArray(  
    const long& src[]      // source array  
)
```

Parameters

src[]

[in] Reference to an array used as a source of elements to copy.

Return Value

true - successful, false - cannot copy the items.

Example:

```
///--- example for CArrayLong::AssignArray(const long &[])  
#include <Arrays\ArrayLong.mqh>  
///---  
long src[];  
///---  
void OnStart()  
{  
    CArrayLong *array=new CArrayLong;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- assign another array  
    if(!array.AssignArray(src))  
    {  
        printf("Array assigned error");  
        delete array;  
        return;  
    }  
    ///--- use array  
    ///--- . . .  
    ///--- delete array  
    delete array;  
}
```

AssignArray

Copies the elements of one array to another.

```
bool AssignArray(  
    const CArrayLong* src      // pointer to the source  
)
```

Parameters

src

[in] Pointer to an instance of the CArrayLong class used as a source of elements to copy.

Return Value

true - successful, false - cannot copy the elements.

Example:

```
///--- example for CArrayLong::AssignArray(const CArrayLong*)  
#include <Arrays\ArrayLong.mqh>  
///---  
void OnStart()  
{  
    CArrayLong *array=new CArrayLong;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- create source array  
    CArrayLong *src =new CArrayLong;  
    if(src==NULL)  
    {  
        printf("Object create error");  
        delete array;  
        return;  
    }  
    ///--- add source arrays elements  
    ///--- . . .  
    ///--- assign another array  
    if(!array.AssignArray(src))  
    {  
        printf("Array assigned error");  
        delete src;  
        delete array;  
        return;  
    }  
    ///--- arrays is identical  
    ///--- delete source array
```

```
delete src;  
//--- use array  
//--- . . .  
//--- delete array  
delete array;  
}
```

Update

Changes the element at the specified array position.

```
bool Update(  
    int    pos,          // position  
    long   element       // value  
)
```

Parameters

pos

[in] Position of the element in the array to change

element

[in] New value of the element

Return Value

true - successful, false - cannot change the element.

Example:

```
//--- example for CArrayLong::Update(int,long)  
#include <Arrays\ArrayLong.mqh>  
//---  
void OnStart()  
{  
    CArrayLong *array=new CArrayLong;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- update element  
    if(!array.Update(0,1000000))  
    {  
        printf("Update error");  
        delete array;  
        return;  
    }  
    //--- delete array  
    delete array;  
}
```

Shift

Moves an item from a given position in the array to the specified offset.

```
bool Shift(  
    int pos,          // position  
    int shift         // shift  
)
```

Parameters

pos

[in] Position of the moved element in the array

shift

[in] The shift value (both positive and negative).

Return Value

true - successful, false - cannot move the element.

Example:

```
//--- example for CArrayLong::Shift(int,int)  
#include <Arrays\ArrayLong.mqh>  
//---  
void OnStart()  
{  
    CArrayLong *array=new CArrayLong;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- shift element  
    if(!array.Shift(10,-5))  
    {  
        printf("Shift error");  
        delete array;  
        return;  
    }  
    //--- delete array  
    delete array;  
}
```

Delete

Removes the element from the specified array position.

```
bool Delete(  
    int pos    // position  
)
```

Parameters

pos

[in] Position of the array element to be removed.

Return Value

true - successful, false - cannot remove the element.

Example:

```
///--- example for CArrayLong::Delete(int)  
#include <Arrays\ArrayLong.mqh>  
///---  
void OnStart()  
{  
    CArrayLong *array=new CArrayLong;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- delete element  
    if(!array.Delete(0))  
    {  
        printf("Delete error");  
        delete array;  
        return;  
    }  
    ///--- delete array  
    delete array;  
}
```

DeleteRange

Deletes a group of elements from the specified array position.

```
bool DeleteRange(  
    int from,      // position of the first element  
    int to         // position of the last element  
)
```

Parameters

from

[in] Position of the first array element to be removed.

to

[in] Position of the last array element to be removed.

Return Value

true - successful, false - cannot remove the elements.

Example:

```
//--- example for CArrayLong::DeleteRange(int,int)  
#include <Arrays\ArrayLong.mqh>  
//---  
void OnStart()  
{  
    CArrayLong *array=new CArrayLong;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- delete elements  
    if(!array.DeleteRange(0,10))  
    {  
        printf("Delete error");  
        delete array;  
        return;  
    }  
    //--- delete array  
    delete array;  
}
```

At

Gets the element from the specified array position.

```
long At(  
    int pos    // position  
    ) const
```

Parameters

pos

[in] Position of the desired element in the array.

Return Value

The value of the element - success, LONG_MAX - there was an attempt to get an element from a non-existing position (the last error code is ERR_OUT_OF_RANGE).

Note

Of course, LONG_MAX may be a valid value of an array element. Therefore, always check the last error code after receiving such a value.

Example:

```
///--- example for CArrayLong::At(int)  
#include <Arrays\ArrayLong.mqh>  
///---  
void OnStart()  
{  
    CArrayLong *array=new CArrayLong;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    for(int i=0;i<array.Total();i++)  
    {  
        long result=array.At(i);  
        if(result==LONG_MAX && GetLastError()==ERR_OUT_OF_RANGE)  
        {  
            ///--- Error reading from the array  
            printf("Get element error");  
            delete array;  
            return;  
        }  
        ///--- use element  
        ///--- . . .  
    }  
}
```

```
//--- delete array  
delete array;  
}
```

CompareArray

Compares the array with another one.

```
bool CompareArray(  
    const long& src[]      // source array  
    ) const
```

Parameters

src[]

[in] Reference to an array used as a source of elements for comparison.

Return Value

true - arrays are equal, false - arrays are not equal.

Example:

```
//--- example for CArrayLong::CompareArray(const long &[])  
#include <Arrays\ArrayLong.mqh>  
//---  
long src[];  
//---  
void OnStart()  
{  
    CArrayLong *array=new CArrayLong;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- compare with another array  
    int result=array.CompareArray(src);  
    //--- delete array  
    delete array;  
}
```

CompareArrayconst

Compares the array with another one.

```
bool CompareArrayconst(  
    const CArrayLong* src      // pointer to the source  
    ) const
```

Parameters

src

[in] Pointer to an instance of the CArrayLong class used as a source of elements for comparison.

Return Value

true - arrays are equal, false - arrays are not equal.

Example:

```
///--- example for CArrayLong::CompareArray(const CArrayLong*)  
#include <Arrays\ArrayLong.mqh>  
///---  
void OnStart()  
{  
    CArrayLong *array=new CArrayLong;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- create source array  
    CArrayLong *src=new CArrayLong;  
    if(src==NULL)  
    {  
        printf("Object create error");  
        delete array;  
        return;  
    }  
    ///--- add source arrays elements  
    ///--- . . .  
    ///--- compare with another array  
    int result=array.CompareArray(src);  
    ///--- delete arrays  
    delete src;  
    delete array;  
}
```

InsertSort

Inserts an element in a sorted array.

```
bool InsertSort(  
    long element    // element to insert  
)
```

Parameters

element

[in] Value of the element to be inserted into a sorted array

Return Value

true - successful, false - cannot insert the element.

Example:

```
///--- example for CArrayLong::InsertSort(long)  
#include <Arrays\ArrayLong.mqh>  
///---  
void OnStart()  
{  
    CArrayLong *array=new CArrayLong;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- sort array  
    array.Sort();  
    ///--- insert element  
    if(!array.InsertSort(1000000))  
    {  
        printf("Insert error");  
        delete array;  
        return;  
    }  
    ///--- delete array  
    delete array;  
}
```

Search

Searches for an element equal to the sample in the sorted array.

```
int Search(  
    long element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayLong::Search(long)  
#include <Arrays\ArrayLong.mqh>  
//---  
void OnStart()  
{  
    CArrayLong *array=new CArrayLong;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.Search(1000000)!=-1) printf("Element found");  
    else                          printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchGreat

Searches for an element with a value exceeding the value of the sample in the sorted array.

```
int SearchGreat(  
    long element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayLong::SearchGreat(long)  
#include <Arrays\ArrayLong.mqh>  
//---  
void OnStart()  
{  
    CArrayLong *array=new CArrayLong;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.SearchGreat(1000000) != -1) printf("Element found");  
    else                                printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchLess

Searches for an element with a value less than the value of the sample in the sorted array.

```
int SearchLess(  
    long element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayLong::SearchLess(long)  
#include <Arrays\ArrayLong.mqh>  
//---  
void OnStart()  
{  
    CArrayLong *array=new CArrayLong;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.SearchLess(1000000)!=-1) printf("Element found");  
    else                             printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchGreatOrEqual

Searches for an element with a value greater than or equal to the value of the sample in the sorted array.

```
int SearchGreatOrEqual(  
    long element    // sample  
) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayLong::SearchGreatOrEqual(long)  
#include <Arrays\ArrayLong.mqh>  
//---  
void OnStart()  
{  
    CArrayLong *array=new CArrayLong;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.SearchGreatOrEqual(1000000)!=-1) printf("Element found");  
    else                                     printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchLessOrEqual

Searches for an element with a value less than or equal to the value of the sample in the sorted array.

```
int SearchLessOrEqual(  
    long element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayLong::SearchLessOrEqual(long)  
#include <Arrays\ArrayLong.mqh>  
//---  
void OnStart()  
{  
    CArrayLong *array=new CArrayLong;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.SearchLessOrEqual(1000000) != -1) printf("Element found");  
    else                                     printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchFirst

Searches for the first element equal to the sample in the sorted array.

```
int SearchFirst(  
    long element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayLong::SearchFirst(long)  
#include <Arrays\ArrayLong.mqh>  
//---  
void OnStart()  
{  
    CArrayLong *array=new CArrayLong;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.SearchFirst(1000000)!=-1) printf("Element found");  
    else                             printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchLast

Searches for the last element equal to the sample in the sorted array.

```
int SearchLast(  
    long element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayLong::SearchLast(long)  
#include <Arrays\ArrayLong.mqh>  
//---  
void OnStart()  
{  
    CArrayLong *array=new CArrayLong;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.SearchLast(1000000)!=-1) printf("Element found");  
    else                             printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchLinear

Searches for the element equal to the sample in the array.

```
int SearchLinear(  
    long element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Note

The method uses the linear search (or sequential search) algorithm for unsorted arrays.

Example:

```
///--- example for CArrayLong::SearchLinear(long)  
#include <Arrays\ArrayLong.mqh>  
///---  
void OnStart()  
{  
    CArrayLong *array=new CArrayLong;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- search element  
    if(array.SearchLinear(1000000) != -1) printf("Element found");  
    else                                printf("Element not found");  
    ///--- delete array  
    delete array;  
}
```

Save

Saves data array in the file.

```
virtual bool Save(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CArrayLong::Save(int)  
#include <Arrays\ArrayLong.mqh>  
//---  
void OnStart()  
{  
    int file_handle;  
    CArrayLong *array=new CArrayLong;  
    //---  
    if(array!=NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add 100 arrays elements  
    for(int i=0;i<100;i++)  
    {  
        array.Add(i);  
    }  
    //--- open file  
    file_handle=FileOpen("MyFile.bin",FILE_WRITE|FILE_BIN|FILE_ANSI);  
    if(file_handle>=0)  
    {  
        if(!array.Save(file_handle))  
        {  
            //--- file save error  
            printf("File save: Error %d!",GetLastError());  
            delete array;  
            FileClose(file_handle);  
            //---  
            return;  
        }  
        FileClose(file_handle);  
    }
```

```
    }  
    delete array;  
}
```

Load

Loads data array from the file.

```
virtual bool Load(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CArrayLong::Load(int)  
#include <Arrays\ArrayLong.mqh>  
//---  
void OnStart()  
{  
    int file_handle;  
    CArrayLong *array=new CArrayLong;  
    //---  
    if(array!=NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- open file  
    file_handle=FileOpen("MyFile.bin",FILE_READ|FILE_BIN|FILE_ANSI);  
    if(file_handle>=0)  
    {  
        if(!array.Load(file_handle))  
        {  
            //--- file load error  
            printf("File load: Error %d!",GetLastError());  
            delete array;  
            FileClose(file_handle);  
            //---  
            return;  
        }  
        FileClose(file_handle);  
    }  
    //--- use arrays elements  
    for(int i=0;i<array.Total();i++)  
    {  
        printf("Element[%d] = %I64",i,array.At(i));  
    }  
}
```

```
    }  
    delete array;  
}
```

Type

Gets the array type identifier.

```
virtual int Type() const
```

Return Value

Array type identifier (for CArrayLong - 84).

Example:

```
//--- example for CArrayLong::Type()
#include <Arrays\ArrayLong.mqh>
//---
void OnStart()
{
    CArrayLong *array=new CArrayLong;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- get array type
    int type=array.Type();
    //--- delete array
    delete array;
}
```

CArrayFloat

CArrayFloat class is a class of dynamic array of float variables.

Description

The CArrayFloat class provides the ability to work with a dynamic array of float variables. The class allows adding/inserting/deleting array elements, performing an array sorting, and searching in a sorted array. In addition, methods of working with files have been implemented.

Declaration

```
class CArrayFloat : public CArray
```

Title

```
#include <Arrays\ArrayFloat.mqh>
```

Inheritance hierarchy

[CObject](#)

[CArray](#)

CArrayFloat

Class Methods by Groups

Attributes	
Delta	Sets the comparison tolerance
Memory control	
Reserve	Allocates memory to increase the size of the array
Resize	Sets a new (smaller) size of the array
Shutdown	Clears the array with a full memory release
Add methods	
Add	Adds an element to the end of the array
AddArray	Adds elements of one array to the end of another
AddArray	Adds elements of one array to the end of another
Insert	Inserts an element to the specified position in the array
InsertArray	Inserts to an array elements from another array from the specified position

InsertArray	Inserts to an array elements from another array from the specified position
AssignArray	Copies the elements of one array to another
AssignArray	Copies the elements of one array to another
Update methods	
Update	Changes the element at the specified array position
Shift	Moves an element from a given position in the array to the specified offset
Delete methods	
Delete	Removes the element from the specified array position
DeleteRange	Deletes a group of elements from the specified array position
Access methods	
At	Gets the element from the specified array position
Compare methods	
CompareArray	Compares the array with another one
CompareArray	Compares the array with another one
Sorted array operations	
InsertSort	Inserts an element in a sorted array
Search	Searches for an element equal to the sample in the sorted array
SearchGreat	Searches for an element with a value exceeding the value of the sample in the sorted array
SearchLess	Searches for an element with a value less than the value of the sample in the sorted array
SearchGreatOrEqual	Searches for an element with a value greater than or equal to the value of the sample in the sorted array
SearchLessOrEqual	Searches for an element with a value less than or equal to the value of the sample in the sorted array
SearchFirst	Searches for the first element equal to the sample in the sorted array

SearchLast	Searches for the last element equal to the sample in the sorted array
SearchLinear	Searches for the element equal to the sample in the array
Input/output	
virtual Save	Saves data array in the file
virtual Load	Loads data array from the file
virtual Type	Gets the type identifier of the array

Methods inherited from class CObject

Prev, Prev, Next, Next, [Compare](#)

Methods inherited from class CArray

[Step](#), [Step](#), [Total](#), [Available](#), [Max](#), [IsSorted](#), [SortMode](#), [Clear](#), [Sort](#)

Delta

Sets the comparison tolerance.

```
void Delta(  
    float delta    // tolerance  
)
```

Parameters

delta

[in] The new value of the comparison tolerance.

Return Value

None

Note

Comparison tolerance is used in the search. Values are considered equal if their difference is less than or equal to tolerance. The default tolerance is 0.0.

Example:

```
///--- example for CArrayFloat::Delta(float)  
#include <Arrays\ArrayFloat.mqh>  
///---  
void OnStart()  
{  
    CArrayFloat *array=new CArrayFloat;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- set compare variation  
    array.Delta(0.001);  
    ///--- use array  
    ///--- . . .  
    ///--- delete array  
    delete array;  
}
```

Reserve

Allocates memory to increase the size of the array.

```
bool Reserve (
    int size      // number
)
```

Parameters

size

[in] The number of additional elements of the array.

Return Value

true - successful, false - there was an attempt to request for an amount less than or equal to zero, or failed to increase the array.

Note

To reduce fragmentation of memory, the array size is changed using the step previously determined by the Step(int) method or the default step of 16.

Example:

```
//--- example for CArrayFloat::Reserve(int)
#include <Arrays\ArrayFloat.mqh>
//---
void OnStart()
{
    CArrayFloat *array=new CArrayFloat;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- reserve memory
    if(!array.Reserve(1024))
    {
        printf("Reserve error");
        delete array;
        return;
    }
    //--- use array
    //--- . . .
    //--- delete array
    delete array;
}
```

Resize

Sets a new (smaller) size of the array.

```
bool  Resize(  
    int  size      // size  
)
```

Parameters

size

[in] New size of the array.

Return Value

true - successful, false - there was an attempt to set the size less than or equal to zero.

Note

Changing the size of the array allows using the memory optimally. Excessive elements on the right are lost. To reduce fragmentation of memory, the array size is changed by the step previously determined by the Step(int) method or the default step of 16.

Example:

```
///--- example for CArrayFloat::Resize(int)  
#include <Arrays\ArrayFloat.mqh>  
///---  
void OnStart()  
{  
    CArrayFloat *array=new CArrayFloat;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- resize array  
    if(!array.Resize(10))  
    {  
        printf("Resize error");  
        delete array;  
        return;  
    }  
    ///--- delete array  
    delete array;  
}
```

Shutdown

Clears the array with a full memory release.

```
bool Shutdown()
```

Return Value

true - successful, false - error.

Example:

```
//--- example for CArrayFloat::Shutdown()
#include <Arrays\ArrayFloat.mqh>
//---
void OnStart()
{
    CArrayFloat *array=new CArrayFloat;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- . . .
    //--- shutdown array
    if(!array.Shutdown())
    {
        printf("Shutdown error");
        delete array;
        return;
    }
    //--- delete array
    delete array;
}
```

Add

Adds an element to the end of the array.

```
bool Add(  
    float element    // element to add  
)
```

Parameters

element

[in] Value of the element to add to the array.

Return Value

true - successful, false - cannot add an element.

Example:

```
///--- example for CArrayFloat::Add(float)  
#include <Arrays\ArrayFloat.mqh>  
///---  
void OnStart()  
{  
    CArrayFloat *array=new CArrayFloat;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    for(int i=0;i<100;i++)  
    {  
        if(!array.Add(i))  
        {  
            printf("Element addition error");  
            delete array;  
            return;  
        }  
    }  
    ///--- use array  
    ///--- . . .  
    ///--- delete array  
    delete array;  
}
```

AddArray

Adds elements of one array to the end of another.

```
bool AddArray(  
    const float& src[]      // source array  
)
```

Parameters

src[]

[in] Reference to an array of source elements to add.

Return Value

true - successful, false - cannot add items.

Example:

```
///--- example for CArrayFloat::AddArray(const float &[])  
#include <Arrays\ArrayFloat.mqh>  
///---  
float src[];  
///---  
void OnStart()  
{  
    CArrayFloat *array=new CArrayFloat;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add another array  
    if(!array.AddArray(src))  
    {  
        printf("Array addition error");  
        delete array;  
        return;  
    }  
    ///--- use array  
    ///--- . . .  
    ///--- delete array  
    delete array;  
}
```

AddArray

Adds elements of one array to the end of another.

```
bool AddArray(  
    const CArrayFloat* src      // pointer to the source  
)
```

Parameters

src

[in] Pointer to an instance of CArrayFloat class used as a source of elements to add.

Return Value

true - successful, false - cannot add items.

Example:

```
///--- example for CArrayFloat::AddArray(const CArrayFloat*)  
#include <Arrays\ArrayFloat.mqh>  
///---  
void OnStart()  
{  
    CArrayFloat *array=new CArrayFloat;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- create source array  
    CArrayFloat *src=new CArrayFloat;  
    if(src==NULL)  
    {  
        printf("Object create error");  
        delete array;  
        return;  
    }  
    ///--- add source arrays elements  
    ///--- . . .  
    ///--- add another array  
    if(!array.AddArray(src))  
    {  
        printf("Array addition error");  
        delete src;  
        delete array;  
        return;  
    }  
    ///--- delete source array  
    delete src;
```

```
//--- use array  
//--- . . .  
//--- delete array  
delete array;  
}
```

Insert

Inserts an element to the specified position in the array.

```
bool Insert(  
    float element,    // element to insert  
    int pos           // position  
)
```

Parameters

element

[in] Value of the element to be inserted into an array

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert the element.

Example:

```
//--- example for CArrayFloat::Insert(float,int)  
#include <Arrays\ArrayFloat.mqh>  
//---  
void OnStart()  
{  
    CArrayFloat *array=new CArrayFloat;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- insert elements  
    for(int i=0;i<100;i++)  
    {  
        if(!array.Insert(i,0))  
        {  
            printf("Insert error");  
            delete array;  
            return;  
        }  
    }  
    //--- use array  
    //--- . . .  
    //--- delete array  
    delete array;  
}
```

InsertArray

Inserts elements of one array from the specified position of another array.

```
bool InsertArray(  
    const float& src[],    // source array  
    int pos               // position  
)
```

Parameters

src[]

[in] Reference to an array used as a source of elements to insert

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert items.

Example:

```
//--- example for CArrayFloat::InsertArray(const float &[],int)  
#include <Arrays\ArrayFloat.mqh>  
//---  
float src[];  
//---  
void OnStart()  
{  
    CArrayFloat *array=new CArrayFloat;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- insert another array  
    if(!array.InsertArray(src,0))  
    {  
        printf("Array inserting error");  
        delete array;  
        return;  
    }  
    //--- use array  
    //--- . . .  
    //--- delete array  
    delete array;  
}
```

InsertArray

Inserts elements of one array from the specified position of another array.

```
bool InsertArray(  
    CArrayFloat* src,      // pointer to the source  
    int pos               // position  
)
```

Parameters

src

[in] Pointer to an instance of the CArrayFloat class used as a source of elements to insert.

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert items.

Example:

```
//--- example for CArrayFloat::InsertArray(const CArrayFloat*,int)  
#include <Arrays\ArrayFloat.mqh>  
//---  
void OnStart()  
{  
    CArrayFloat *array=new CArrayFloat;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- create source array  
    CArrayFloat *src=new CArrayFloat;  
    if(src==NULL)  
    {  
        printf("Object create error");  
        delete array;  
        return;  
    }  
    //--- add source arrays elements  
    //--- . . .  
    //--- insert another array  
    if(!array.InsertArray(src,0))  
    {  
        printf("Array inserting error");  
        delete src;  
        delete array;  
    }  
}
```

```
        return;  
    }  
    //--- delete source array  
    delete src;  
    //--- use array  
    //--- . . .  
    //--- delete array  
    delete array;  
}
```

AssignArray

Copies the elements of one array to another.

```
bool AssignArray(  
    const float& src[]      // source array  
)
```

Parameters

src[]

[in] Reference to an array used as a source of elements to copy.

Return Value

true - successful, false - cannot copy the items.

Example:

```
///--- example for CArrayFloat::AssignArray(const float &[])  
#include <Arrays\ArrayFloat.mqh>  
///---  
float src[];  
///---  
void OnStart()  
{  
    CArrayFloat *array=new CArrayFloat;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- assign another array  
    if(!array.AssignArray(src))  
    {  
        printf("Array assigned error");  
        delete array;  
        return;  
    }  
    ///--- use array  
    ///--- . . .  
    ///--- delete array  
    delete array;  
}
```

AssignArray

Copies the elements of one array to another.

```
bool AssignArray(  
    const CArrayFloat* src      // pointer to the source  
)
```

Parameters

src

[in] Pointer to an instance of the CArrayFloat class used as a source of elements to copy.

Return Value

true - successful, false - cannot copy the elements.

Example:

```
///--- example for CArrayFloat::AssignArray(const CArrayFloat*)  
#include <Arrays\ArrayFloat.mqh>  
///---  
void OnStart()  
{  
    CArrayFloat *array=new CArrayFloat;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- create source array  
    CArrayFloat *src =new CArrayFloat;  
    if(src==NULL)  
    {  
        printf("Object create error");  
        delete array;  
        return;  
    }  
    ///--- add source arrays elements  
    ///--- . . .  
    ///--- assign another array  
    if(!array.AssignArray(src))  
    {  
        printf("Array assigned error");  
        delete src;  
        delete array;  
        return;  
    }  
    ///--- arrays is identical  
    ///--- delete source array
```

```
delete src;  
//--- use array  
//--- . . .  
//--- delete array  
delete array;  
}
```

Update

Changes the element at the specified array position.

```
bool Update(  
    int    pos,          // position  
    float  element       // value  
)
```

Parameters

pos

[in] Position of the element in the array to change

element

[in] New value of the element

Return Value

true - successful, false - cannot change the element.

Example:

```
//--- example for CArrayFloat::Update(int,float)  
#include <Arrays\ArrayFloat.mqh>  
//---  
void OnStart()  
{  
    CArrayFloat *array=new CArrayFloat;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- update element  
    if(!array.Update(0,100.0))  
    {  
        printf("Update error");  
        delete array;  
        return;  
    }  
    //--- delete array  
    delete array;  
}
```

Shift

Moves an item from a given position in the array to the specified offset.

```
bool Shift(  
    int pos,          // position  
    int shift         // shift  
)
```

Parameters

pos

[in] Position of the moved element in the array

shift

[in] The shift value (both positive and negative).

Return Value

true - successful, false - cannot move the element.

Example:

```
//--- example for CArrayFloat::Shift(int,int)  
#include <Arrays\ArrayFloat.mqh>  
//---  
void OnStart()  
{  
    CArrayFloat *array=new CArrayFloat;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- shift element  
    if(!array.Shift(10,-5))  
    {  
        printf("Shift error");  
        delete array;  
        return;  
    }  
    //--- delete array  
    delete array;  
}
```

Delete

Removes the element from the specified array position.

```
bool Delete(  
    int pos    // position  
)
```

Parameters

pos

[in] Position of the array element to be removed.

Return Value

true - successful, false - cannot remove the element.

Example:

```
///--- example for CArrayFloat::Delete(int)  
#include <Arrays\ArrayFloat.mqh>  
///---  
void OnStart()  
{  
    CArrayFloat *array=new CArrayFloat;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- delete element  
    if(!array.Delete(0))  
    {  
        printf("Delete error");  
        delete array;  
        return;  
    }  
    ///--- delete array  
    delete array;  
}
```

DeleteRange

Deletes a group of elements from the specified array position.

```
bool DeleteRange(  
    int from,      // position of the first element  
    int to         // position of last element  
)
```

Parameters

from

[in] Position of the first array element to be removed.

to

[in] Position of the last array element to be removed.

Return Value

true - successful, false - cannot remove the elements.

Example:

```
//--- example for CArrayFloat::DeleteRange(int,int)  
#include <Arrays\ArrayFloat.mqh>  
//---  
void OnStart()  
{  
    CArrayFloat *array=new CArrayFloat;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- delete elements  
    if(!array.DeleteRange(0,10))  
    {  
        printf("Delete error");  
        delete array;  
        return;  
    }  
    //--- delete array  
    delete array;  
}
```

At

Gets the element from the specified array position.

```
float At(  
    int pos    // position  
) const
```

Parameters

pos

[in] Position of the desired element in the array.

Return Value

The value of the element - success, FLT_MAX - there was an attempt to get an element from a non-existing position (the last error code is ERR_OUT_OF_RANGE).

Note

Of course, FLT_MAX may be a valid value of an array element. Therefore, always check the last error code after receiving such a value.

Example:

```
///--- example for CArrayFloat::At(int)  
#include <Arrays\ArrayFloat.mqh>  
///---  
void OnStart()  
{  
    CArrayFloat *array=new CArrayFloat;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    for(int i=0;i<array.Total();i++)  
    {  
        float result=array.At(i);  
        if(result==FLT_MAX && GetLastError()==ERR_OUT_OF_RANGE)  
        {  
            ///--- error reading from array  
            printf("Get element error");  
            delete array;  
            return;  
        }  
        ///--- use element  
        ///--- . . .  
    }  
}
```

```
//--- delete array  
delete array;  
}
```

CompareArray

Compares the array with another one.

```
bool CompareArray(  
    const float& src[]    // source array  
    ) const
```

Parameters

src[]

[in] Reference to an array used as a source of elements for comparison.

Return Value

true - arrays are equal, false - arrays are not equal.

Example:

```
//--- example for CArrayFloat::CompareArray(const float &[])  
#include <Arrays\ArrayFloat.mqh>  
//---  
float src[];  
//---  
void OnStart()  
{  
    CArrayFloat *array=new CArrayFloat;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- compare with another array  
    int result=array.CompareArray(src);  
    //--- delete array  
    delete array;  
}
```

AssignArrayconst

Compares the array with another one.

```
bool AssignArrayconst(  
    const CArrayFloat* src      // pointer to the source  
    ) const
```

Parameters

src

[in] Pointer to an instance of the CArrayFloat class used as a source of elements for comparison.

Return Value

true - successful, false - cannot copy the items.

Example:

```
///--- example for CArrayFloat::CompareArray(const CArrayFloat*)  
#include <Arrays\ArrayFloat.mqh>  
///---  
void OnStart()  
{  
    CArrayFloat *array=new CArrayFloat;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- create source array  
    CArrayFloat *src=new CArrayFloat;  
    if(src==NULL)  
    {  
        printf("Object create error");  
        delete array;  
        return;  
    }  
    ///--- add source arrays elements  
    ///--- . . .  
    ///--- compare with another array  
    int result=array.CompareArray(src);  
    ///--- delete arrays  
    delete src;  
    delete array;  
}
```

InsertSort

Inserts an element in a sorted array.

```
bool InsertSort(  
    float element    // element to insert  
)
```

Parameters

element

[in] Value of the element to be inserted into a sorted array

Return Value

true - successful, false - cannot insert the element.

Example:

```
///--- example for CArrayFloat::InsertSort(float)  
#include <Arrays\ArrayFloat.mqh>  
///---  
void OnStart()  
{  
    CArrayFloat *array=new CArrayFloat;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- sort array  
    array.Sort();  
    ///--- insert element  
    if(!array.InsertSort(100.0))  
    {  
        printf("Insert error");  
        delete array;  
        return;  
    }  
    ///--- delete array  
    delete array;  
}
```

Search

Searches for an element equal to the sample in the sorted array.

```
int Search(  
    float element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayFloat::Search(float)  
#include <Arrays\ArrayFloat.mqh>  
//---  
void OnStart()  
{  
    CArrayFloat *array=new CArrayFloat;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.Search(100.0)!=-1) printf("Element found");  
    else                        printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchGreat

Searches for an element with a value exceeding the value of the sample in the sorted array.

```
int SearchGreat(  
    float element    // sample  
) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayFloat::SearchGreat(float)  
#include <Arrays\ArrayFloat.mqh>  
//---  
void OnStart()  
{  
    CArrayFloat *array=new CArrayFloat;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.SearchGreat(100.0)!=-1) printf("Element found");  
    else                             printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchLess

Searches for an element with a value less than the value of the sample in the sorted array.

```
int SearchLess(  
    float element    // sample  
) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayFloat:: SearchLess(float)  
#include <Arrays\ArrayFloat.mqh>  
//---  
void OnStart()  
{  
    CArrayFloat *array=new CArrayFloat;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.SearchLess(100.0)!=-1) printf("Element found");  
    else                          printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchGreatOrEqual

Searches for an element with a value greater than or equal to the value of the sample in the sorted array.

```
int SearchGreatOrEqual(  
    float element    // sample  
) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
///--- example for CArrayFloat::SearchGreatOrEqual(float)  
#include <Arrays\ArrayFloat.mqh>  
///---  
void OnStart()  
{  
    CArrayFloat *array=new CArrayFloat;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- sort array  
    array.Sort();  
    ///--- search element  
    if(array.SearchGreatOrEqual(100.0)!=-1) printf("Element found");  
    else                                  printf("Element not found");  
    ///--- delete array  
    delete array;  
}
```

SearchLessOrEqual

Searches for an element with a value less than or equal to the value of the sample in the sorted array.

```
int SearchLessOrEqual(  
    float element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayFloat::SearchLessOrEqual(float)  
#include <Arrays\ArrayFloat.mqh>  
//---  
void OnStart()  
{  
    CArrayFloat *array=new CArrayFloat;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.SearchLessOrEqual(100.0)!=-1) printf("Element found");  
    else                                printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchFirst

Searches for the first element equal to the sample in the sorted array.

```
int SearchFirst(  
    float element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayFloat::SearchFirst(float)  
#include <Arrays\ArrayFloat.mqh>  
//---  
void OnStart()  
{  
    CArrayFloat *array=new CArrayFloat;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.SearchFirst(100.0)!=-1) printf("Element found");  
    else                             printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchLast

Searches for the last element equal to the sample in the sorted array.

```
int SearchLast(  
    float element    // sample  
) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
///--- example for CArrayFloat::SearchLast(float)  
#include <Arrays\ArrayFloat.mqh>  
///---  
void OnStart()  
{  
    CArrayFloat *array=new CArrayFloat;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- sort array  
    array.Sort();  
    ///--- search element  
    if(array.SearchLast(100.0)!=-1) printf("Element found");  
    else                           printf("Element not found");  
    ///--- delete array  
    delete array;  
}
```

SearchLinear

Searches for the element equal to the sample in the array.

```
int SearchLinear(  
    float element    // sample  
) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Note

The method uses the linear search (or sequential search) algorithm for unsorted arrays.

Example:

```
///--- example for CArrayFloat::SearchLinear(float)  
#include <Arrays\ArrayFloat.mqh>  
///---  
void OnStart()  
{  
    CArrayFloat *array=new CArrayFloat;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- search element  
    if(array.SearchLinear(100.0) != -1) printf("Element found");  
    else                               printf("Element not found");  
    ///--- delete array  
    delete array;  
}
```

Save

Saves data array in the file.

```
virtual bool Save(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CArrayFloat::Save(int)  
#include <Arrays\ArrayFloat.mqh>  
//---  
void OnStart()  
{  
    int file_handle;  
    CArrayFloat *array=new CArrayFloat;  
    //---  
    if(array!=NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add 100 arrays elements  
    for(int i=0;i<100;i++)  
    {  
        array.Add(i);  
    }  
    //--- open file  
    file_handle=FileOpen("MyFile.bin",FILE_WRITE|FILE_BIN|FILE_ANSI);  
    if(file_handle>=0)  
    {  
        if(!array.Save(file_handle))  
        {  
            //--- file save error  
            printf("File save: Error %d!",GetLastError());  
            delete array;  
            FileClose(file_handle);  
            //---  
            return;  
        }  
        FileClose(file_handle);  
    }
```

```
    }  
    delete array;  
}
```

Load

Loads data array from the file.

```
virtual bool Load(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CArrayFloat::Load(int)  
#include <Arrays\ArrayFloat.mqh>  
//---  
void OnStart()  
{  
    int file_handle;  
    CArrayFloat *array=new CArrayFloat;  
    //---  
    if(array!=NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- open file  
    file_handle=FileOpen("MyFile.bin",FILE_READ|FILE_BIN|FILE_ANSI);  
    if(file_handle>=0)  
    {  
        if(!array.Load(file_handle))  
        {  
            //--- file load error  
            printf("File load: Error %d!",GetLastError());  
            delete array;  
            FileClose(file_handle);  
            //---  
            return;  
        }  
        FileClose(file_handle);  
    }  
    //--- use arrays elements  
    for(int i=0;i<array.Total();i++)  
    {  
        printf("Element[%d] = %f",i,array.At(i));  
    }  
}
```

```
    }  
    delete array;  
}
```

Type

Gets the array type identifier.

```
virtual int Type() const
```

Return Value

Array type identifier (for CArrayFloat - 87).

Example:

```
//--- example for CArrayFloat::Type()
#include <Arrays\ArrayFloat.mqh>
//---
void OnStart()
{
    CArrayFloat *array=new CArrayFloat;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- get array type
    int type=array.Type();
    //--- delete array
    delete array;
}
```

CArrayDouble

CArrayDouble class is a class of dynamic array of double variables.

Description

The CArrayDouble class provides the ability to work with a dynamic array of double variables. The class allows adding/inserting/deleting array elements, performing an array sorting, and searching in a sorted array. In addition, methods of working with files have been implemented.

Declaration

```
class CArrayDouble : public CArray
```

Title

```
#include <Arrays\ArrayDouble.mqh>
```

Inheritance hierarchy

Class Methods by Groups

Attributes	
Delta	Set the comparison tolerance
Memory control	
Reserve	Allocates memory to increase the size of the array
Resize	Sets a new (smaller) size of the array
Shutdown	Clears the array with a full memory release
Add methods	
Add	Adds an element to the end of the array
AddArray	Adds elements of one array to the end of another
AddArray	Adds elements of one array to the end of another
Insert	Inserts an element to the specified position in the array

InsertArray	Inserts to an array elements from another array from the specified position
InsertArray	Inserts to an array elements from another array from the specified position
AssignArray	Copies the elements of one array to another
AssignArray	Copies the elements of one array to another
Update methods	
Update	Changes the element at the specified array position
Shift	Moves an element from a given position in the array to the specified offset
Delete methods	
Delete	Removes the element from the specified array position
DeleteRange	Deletes a group of elements from the specified array position
Access methods	
At	Gets the element from the specified array position
Compare methods	
CompareArray	Compares the array with another one
CompareArray	Compares the array with another one
Search for min/max	
Minimum	Gets the lowest value index in the specified range
Maximum	Gets the highest value index in the specified range
Sorted array operations	
InsertSort	Inserts an element in a sorted array
Search	Searches for an element equal to the sample in the sorted array
SearchGreat	Searches for an element with a value exceeding the value of the sample in the sorted array
SearchLess	Searches for an element with a value less than the value of the sample in the sorted array

<u>SearchGreatOrEqual</u>	Searches for an element with a value greater than or equal to the value of the sample in the sorted array
<u>SearchLessOrEqual</u>	Searches for an element with a value less than or equal to the value of the sample in the sorted array
<u>SearchFirst</u>	Searches for the first element equal to the sample in the sorted array
<u>SearchLast</u>	Searches for the last element equal to the sample in the sorted array
<u>SearchLinear</u>	Searches for the element equal to the sample in the array
Input/output	
virtual <u>Save</u>	Saves data array in the file
virtual <u>Load</u>	Loads data array from the file
virtual <u>Type</u>	Gets the type identifier of the array

Delta

Sets the comparison tolerance.

```
void Delta(  
    double delta    // tolerance  
)
```

Parameters

delta

[in] The new value of the comparison tolerance.

Return Value

No

Note

Comparison tolerance is used in the search. Values are considered equal if their difference is less than or equal to tolerance. The default tolerance is 0.0.

Example:

```
///--- example for CArrayDouble::Delta(double)  
#include <Arrays\ArrayDouble.mqh>  
///---  
void OnStart()  
{  
    CArrayDouble *array=new CArrayDouble;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- set compare variation  
    array.Delta(0.001);  
    ///--- use array  
    ///--- . . .  
    ///--- delete array  
    delete array;  
}
```

Reserve

Allocates memory to increase the size of the array.

```
bool Reserve (
    int size      // number
)
```

Parameters

size

[in] The number of additional elements of the array.

Return Value

true - successful, false - there was an attempt to request for an amount less than or equal to zero, or failed to increase the array.

Note

To reduce fragmentation of memory, the array size is changed using the step previously determined by the Step(int) method or the default step of 16.

Example:

```
///--- example for CArrayDouble::Reserve(int)
#include <Arrays\ArrayDouble.mqh>
///---
void OnStart()
{
    CArrayDouble *array=new CArrayDouble;
    ///---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    ///--- reserve memory
    if(!array.Reserve(1024))
    {
        printf("Reserve error");
        delete array;
        return;
    }
    ///--- use array
    ///--- . . .
    ///--- delete array
    delete array;
}
```

Resize

Sets a new (smaller) size of the array.

```
bool Resize(  
    int size      // size  
)
```

Parameters

size

[in] New size of the array.

Return Value

true - successful, false - there was an attempt to set the size less than or equal to zero.

Note

Changing the size of the array allows using the memory optimally. Excessive elements on the right are lost. To reduce fragmentation of memory, the array size is changed by the step previously determined by the Step(int) method or the default step of 16.

Example:

```
///--- example for CArrayDouble::Resize(int)  
#include <Arrays\ArrayDouble.mqh>  
///---  
void OnStart()  
{  
    CArrayDouble *array=new CArrayDouble;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- resize array  
    if(!array.Resize(10))  
    {  
        printf("Resize error");  
        delete array;  
        return;  
    }  
    ///--- delete array  
    delete array;  
}
```

Shutdown

Clears the array with a full memory release.

```
bool Shutdown()
```

Return Value

true - successful, false - error.

Example:

```
//--- example for CArrayDouble::Shutdown()
#include <Arrays\ArrayDouble.mqh>
//---
void OnStart()
{
    CArrayDouble *array=new CArrayDouble;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- . . .
    //--- shutdown array
    if(!array.Shutdown())
    {
        printf("Shutdown error");
        delete array;
        return;
    }
    //--- delete array
    delete array;
}
```

Add

Adds an element to the end of the array.

```
bool Add(  
    double element    // element to add  
)
```

Parameters

element

[in] Value of the element to add to the array.

Return Value

true - successful, false - cannot add an element.

Example:

```
///--- example for CArrayDouble::Add(double)  
#include <Arrays\ArrayDouble.mqh>  
///---  
void OnStart()  
{  
    CArrayDouble *array=new CArrayDouble;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    for(int i=0;i<100;i++)  
    {  
        if(!array.Add(i))  
        {  
            printf("Element addition error");  
            delete array;  
            return;  
        }  
    }  
    ///--- use array  
    ///--- . . .  
    ///--- delete array  
    delete array;  
}
```

AddArray

Adds elements of one array to the end of another.

```
bool AddArray(  
    const double& src[]    // source array  
)
```

Parameters

src[]

[in] Reference to an array of source elements to add.

Return Value

true - successful, false - cannot add items.

Example:

```
///--- example for CArrayDouble::AddArray(const double &[])  
#include <Arrays\ArrayDouble.mqh>  
///---  
double src[];  
///---  
void OnStart()  
{  
    CArrayDouble *array=new CArrayDouble;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add another array  
    if(!array.AddArray(src))  
    {  
        printf("Array addition error");  
        delete array;  
        return;  
    }  
    ///--- use array  
    ///--- . . .  
    ///--- delete array  
    delete array;  
}
```

AddArray

Adds elements of one array to the end of another.

```
bool AddArray(  
    const CArrayDouble* src      // pointer to the source  
)
```

Parameters

src

[in] Pointer to an instance of CArrayDouble class used as a source of elements to add.

Return Value

true - successful, false - cannot add items.

Example:

```
///--- example for CArrayDouble::AddArray(const CArrayDouble*)  
#include <Arrays\ArrayDouble.mqh>  
///---  
void OnStart()  
{  
    CArrayDouble *array=new CArrayDouble;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- create source array  
    CArrayDouble *src=new CArrayDouble;  
    if(src==NULL)  
    {  
        printf("Object create error");  
        delete array;  
        return;  
    }  
    ///--- add source arrays elements  
    ///--- . . .  
    ///--- add another array  
    if(!array.AddArray(src))  
    {  
        printf("Array addition error");  
        delete src;  
        delete array;  
        return;  
    }  
    ///--- delete source array  
    delete src;
```

```
//--- use array  
//--- . . .  
//--- delete array  
delete array;  
}
```

Insert

Inserts an element to the specified position in the array.

```
bool Insert(  
    double element,    // element to insert  
    int pos            // position  
)
```

Parameters

element

[in] Value of the element to be inserted into an array

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert the element.

Example:

```
//--- example for CArrayDouble::Insert(double,int)  
#include <Arrays\ArrayDouble.mqh>  
//---  
void OnStart()  
{  
    CArrayDouble *array=new CArrayDouble;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- insert elements  
    for(int i=0;i<100;i++)  
    {  
        if(!array.Insert(i,0))  
        {  
            printf("Insert error");  
            delete array;  
            return;  
        }  
    }  
    //--- use array  
    //--- . . .  
    //--- delete array  
    delete array;  
}
```

InsertArray

Inserts elements of one array from the specified position of another array.

```
bool InsertArray(  
    const double& src[],      // source array  
    int pos                  // position  
)
```

Parameters

src[]

[in] Reference to an array used as a source of elements to insert

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert items.

Example:

```
//--- example for CArrayDouble::InsertArray(const double &[],int)  
#include <Arrays\ArrayDouble.mqh>  
//---  
double src[];  
//---  
void OnStart()  
{  
    CArrayDouble *array=new CArrayDouble;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- insert another array  
    if(!array.InsertArray(src,0))  
    {  
        printf("Array inserting error");  
        delete array;  
        return;  
    }  
    //--- use array  
    //--- . . .  
    //--- delete array  
    delete array;  
}
```

InsertArray

Inserts elements of one array from the specified position of another array.

```
bool InsertArray(  
    CArrayDouble* src,      // pointer to the source  
    int pos                // position  
)
```

Parameters

src

[in] Pointer to an instance of the CArrayDouble class used as a source of elements to insert.

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert items.

Example:

```
//--- example for CArrayDouble::InsertArray(const CArrayDouble*,int)  
#include <Arrays\ArrayDouble.mqh>  
//---  
void OnStart()  
{  
    CArrayDouble *array=new CArrayDouble;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- create source array  
    CArrayDouble *src=new CArrayDouble;  
    if(src==NULL)  
    {  
        printf("Object create error");  
        delete array;  
        return;  
    }  
    //--- add source arrays elements  
    //--- . . .  
    //--- insert another array  
    if(!array.InsertArray(src,0))  
    {  
        printf("Array inserting error");  
        delete src;  
        delete array;  
    }  
}
```

```
        return;  
    }  
    //-- delete source array  
    delete src;  
    //-- use array  
    //-- . . .  
    //-- delete array  
    delete array;  
}
```

AssignArray

Copies the elements of one array to another.

```
bool AssignArray(  
    const double& src[]      // source array  
)
```

Parameters

src[]

[in] Reference to an array used as a source of elements to copy.

Return Value

true - successful, false - cannot copy the items.

Example:

```
///--- example for CArrayDouble::AssignArray(const double &[])  
#include <Arrays\ArrayDouble.mqh>  
///---  
double src[];  
///---  
void OnStart()  
{  
    CArrayDouble *array=new CArrayDouble;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- assign another array  
    if(!array.AssignArray(src))  
    {  
        printf("Array assigned error");  
        delete array;  
        return;  
    }  
    ///--- use array  
    ///--- . . .  
    ///--- delete array  
    delete array;  
}
```

AssignArray

Copies the elements of one array to another.

```
bool AssignArray(  
    const CArrayDouble* src      // pointer to the source  
)
```

Parameters

src

[in] Pointer to an instance of the CArrayDouble class used as a source of elements to copy.

Return Value

true - successful, false - cannot copy the elements.

Example:

```
///--- example for CArrayDouble::AssignArray(const CArrayDouble*)  
#include <Arrays\ArrayDouble.mqh>  
///---  
void OnStart()  
{  
    CArrayDouble *array=new CArrayDouble;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- create source array  
    CArrayDouble *src =new CArrayDouble;  
    if(src==NULL)  
    {  
        printf("Object create error");  
        delete array;  
        return;  
    }  
    ///--- add source arrays elements  
    ///--- . . .  
    ///--- assign another array  
    if(!array.AssignArray(src))  
    {  
        printf("Array assigned error");  
        delete src;  
        delete array;  
        return;  
    }  
    ///--- arrays is identical  
    ///--- delete source array
```

```
delete src;  
//--- use array  
//--- . . .  
//--- delete array  
delete array;  
}
```

Update

Changes the element at the specified array position.

```
bool Update(  
    int    pos,           // position  
    double element       // value  
)
```

Parameters

pos

[in] Position of the element in the array to change

element

[in] New value of the element.

Return Value

true - successful, false - cannot change the element.

Example:

```
//--- example for CArrayDouble::Update(int,double)  
#include <Arrays\ArrayDouble.mqh>  
//---  
void OnStart()  
{  
    CArrayDouble *array=new CArrayDouble;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- update element  
    if(!array.Update(0,100.0))  
    {  
        printf("Update error");  
        delete array;  
        return;  
    }  
    //--- delete array  
    delete array;  
}
```

Shift

Moves an item from a given position in the array to the specified offset.

```
bool Shift(  
    int pos,          // position  
    int shift         // shift  
)
```

Parameters

pos

[in] Position of the moved element in the array

shift

[in] The shift value (both positive and negative).

Return Value

true - successful, false - cannot move the element.

Example:

```
//--- example for CArrayDouble::Shift(int,int)  
#include <Arrays\ArrayDouble.mqh>  
//---  
void OnStart()  
{  
    CArrayDouble *array=new CArrayDouble;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- shift element  
    if(!array.Shift(10,-5))  
    {  
        printf("Shift error");  
        delete array;  
        return;  
    }  
    //--- delete array  
    delete array;  
}
```

Delete

Removes the element from the specified array position.

```
bool Delete(  
    int pos    // position  
)
```

Parameters

pos

[in] Position of the array element to be removed.

Return Value

true - successful, false - cannot remove the element.

Example:

```
///--- example for CArrayDouble::Delete(int)  
#include <Arrays\ArrayDouble.mqh>  
///---  
void OnStart()  
{  
    CArrayDouble *array=new CArrayDouble;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- delete element  
    if(!array.Delete(0))  
    {  
        printf("Delete error");  
        delete array;  
        return;  
    }  
    ///--- delete array  
    delete array;  
}
```

DeleteRange

Deletes a group of elements from the specified array position.

```
bool DeleteRange(  
    int from,      // position of the first element  
    int to         // position of the last element  
)
```

Parameters

from

[in] Position of the first array element to be removed.

to

[in] Position of the last array element to be removed.

Return Value

true - successful, false - cannot remove the elements.

Example:

```
//--- example for CArrayDouble::DeleteRange(int,int)  
#include <Arrays\ArrayDouble.mqh>  
//---  
void OnStart()  
{  
    CArrayDouble *array=new CArrayDouble;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- delete elements  
    if(!array.DeleteRange(0,10))  
    {  
        printf("Delete error");  
        delete array;  
        return;  
    }  
    //--- delete array  
    delete array;  
}
```

At

Gets the element from the specified array position.

```
double At(  
    int pos      // position  
) const
```

Parameters

pos

[in] Position of the desired element in the array.

Return Value

The value of the element - success, DBL_MAX - there was an attempt to get an element from a non-existing position (the last error code is ERR_OUT_OF_RANGE).

Note

Of course, DBL_MAX may be a valid value of an array element. Therefore, always check the last error code after receiving such a value.

Example:

```
///--- example for CArrayDouble::At(int)  
#include <Arrays\ArrayDouble.mqh>  
///---  
void OnStart()  
{  
    CArrayDouble *array=new CArrayDouble;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    for(int i=0;i<array.Total();i++)  
    {  
        double result=array.At(i);  
        if(result==DBL_MAX && GetLastError()==ERR_OUT_OF_RANGE)  
        {  
            ///--- Error reading from the array  
            printf("Get element error");  
            delete array;  
            return;  
        }  
        ///--- use element  
        ///--- . . .  
    }  
}
```

```
//--- delete array  
delete array;  
}
```

CompareArray

Compares the array with another one.

```
bool CompareArray(  
    const double& src[]      // source array  
    ) const
```

Parameters

src[]

[in] Reference to an array used as a source of elements for comparison.

Return Value

true - arrays are equal, false - arrays are not equal.

Example:

```
///--- example for CArrayDouble::CompareArray(const double &[])  
#include <Arrays\ArrayDouble.mqh>  
///---  
double src[];  
///---  
void OnStart()  
{  
    CArrayDouble *array=new CArrayDouble;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- compare with another array  
    int result=array.CompareArray(src);  
    ///--- delete array  
    delete array;  
}
```

CompareArray

Compares the array with another one.

```
bool CompareArray(  
    const CArrayDouble* src      // pointer to the source  
    ) const
```

Parameters

src

[in] Pointer to an instance of the CArrayDouble class used as a source of elements for comparison.

Return Value

true - successful, false - cannot copy the items.

Example:

```
//--- example for CArrayDouble::CompareArray(const CArrayDouble*)  
#include <Arrays\ArrayDouble.mqh>  
//---  
void OnStart()  
{  
    CArrayDouble *array=new CArrayDouble;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- create source array  
    CArrayDouble *src=new CArrayDouble;  
    if(src==NULL)  
    {  
        printf("Object create error");  
        delete array;  
        return;  
    }  
    //--- add source arrays elements  
    //--- . . .  
    //--- compare with another array  
    int result=array.CompareArray(src);  
    //--- delete arrays  
    delete src;  
    delete array;  
}
```

Minimum

Gets index of the lowest element of the array in the specified range.

```
int Minimum(  
    int start,      // starting index  
    int count       // number of elements  
) const
```

Parameters

start

[in] Starting index of the search range.

count

[in] Search range size (number of elements).

Return Value

Index of the lowest element in the specified range.

Maximum

Gets index of the highest element of the array in the specified range.

```
int Maximum(  
    int start,      // starting index  
    int count       // number of elements  
) const
```

Parameters

start

[in] Starting index of the search range.

count

[in] Search range size (number of elements).

Return Value

Index of the highest element in the specified range.

InsertSort

Inserts an element in a sorted array.

```
bool InsertSort(  
    double element    // element to insert  
)
```

Parameters

element

[in] Value of the element to be inserted into a sorted array

Return Value

true - successful, false - cannot insert the element.

Example:

```
///--- example for CArrayDouble::InsertSort(double)  
#include <Arrays\ArrayDouble.mqh>  
///---  
void OnStart()  
{  
    CArrayDouble *array=new CArrayDouble;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- sort array  
    array.Sort();  
    ///--- insert element  
    if(!array.InsertSort(100.0))  
    {  
        printf("Insert error");  
        delete array;  
        return;  
    }  
    ///--- delete array  
    delete array;  
}
```

Search

Searches for an element equal to the sample in the sorted array.

```
int Search(  
    double element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayDouble::Search(double)  
#include <Arrays\ArrayDouble.mqh>  
//---  
void OnStart()  
{  
    CArrayDouble *array=new CArrayDouble;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.Search(100.0)!=-1) printf("Element found");  
    else                        printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchGreat

Searches for an element with a value exceeding the value of the sample in the sorted array.

```
int SearchGreat(  
    double element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayDouble::SearchGreat(double)  
#include <Arrays\ArrayDouble.mqh>  
//---  
void OnStart()  
{  
    CArrayDouble *array=new CArrayDouble;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.SearchGreat(100.0)!=-1) printf("Element found");  
    else                             printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchLess

Searches for an element with a value less than the value of the sample in the sorted array.

```
int SearchLess(  
    double element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayDouble:: SearchLess(double)  
#include <Arrays\ArrayDouble.mqh>  
//---  
void OnStart()  
{  
    CArrayDouble *array=new CArrayDouble;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.SearchLess(100.0)!=-1) printf("Element found");  
    else                           printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchGreatOrEqual

Searches for an element with a value greater than or equal to the value of the sample in the sorted array.

```
int SearchGreatOrEqual(  
    double element    // sample  
) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
///--- example for CArrayDouble::SearchGreatOrEqual(double)  
#include <Arrays\ArrayDouble.mqh>  
///---  
void OnStart()  
{  
    CArrayDouble *array=new CArrayDouble;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- sort array  
    array.Sort();  
    ///--- search element  
    if(array.SearchGreatOrEqual(100.0)!=-1) printf("Element found");  
    else                                  printf("Element not found");  
    ///--- delete array  
    delete array;  
}
```

SearchLessOrEqual

Searches for an element with a value less than or equal to the value of the sample in the sorted array.

```
int SearchLessOrEqual(  
    double element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayDouble::SearchLessOrEqual(double)  
#include <Arrays\ArrayDouble.mqh>  
//---  
void OnStart()  
{  
    CArrayDouble *array=new CArrayDouble;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.SearchLessOrEqual(100.0)!=-1) printf("Element found");  
    else                                printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchFirst

Searches for the first element equal to the sample in the sorted array.

```
int SearchFirst(  
    double element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayDouble::SearchFirst(double)  
#include <Arrays\ArrayDouble.mqh>  
//---  
void OnStart()  
{  
    CArrayDouble *array=new CArrayDouble;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.SearchFirst(100.0)!=-1) printf("Element found");  
    else                             printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchLast

Searches for the last element equal to the sample in the sorted array.

```
int SearchLast(  
    double element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
///--- example for CArrayDouble::SearchLast(double)  
#include <Arrays\ArrayDouble.mqh>  
///---  
void OnStart()  
{  
    CArrayDouble *array=new CArrayDouble;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- sort array  
    array.Sort();  
    ///--- search element  
    if(array.SearchLast(100.0)!=-1) printf("Element found");  
    else                           printf("Element not found");  
    ///--- delete array  
    delete array;  
}
```

SearchLinear

Searches for the element equal to the sample in the array.

```
int SearchLinear(  
    double element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Note

The method uses the linear search (or sequential search) algorithm for unsorted arrays.

Example:

```
//--- example for CArrayDouble::SearchLinear(double)  
#include <Arrays\ArrayDouble.mqh>  
//---  
void OnStart()  
{  
    CArrayDouble *array=new CArrayDouble;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- search element  
    if(array.SearchLinear(100.0) != -1) printf("Element found");  
    else                               printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

Save

Saves data array in the file.

```
virtual bool Save(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CArrayDouble::Save(int)  
#include <Arrays\ArrayDouble.mqh>  
//---  
void OnStart()  
{  
    int file_handle;  
    CArrayDouble *array=new CArrayDouble;  
    //---  
    if(array!=NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add 100 arrays elements  
    for(int i=0;i<100;i++)  
    {  
        array.Add(i);  
    }  
    //--- open file  
    file_handle=FileOpen("MyFile.bin",FILE_WRITE|FILE_BIN|FILE_ANSI);  
    if(file_handle>=0)  
    {  
        if(!array.Save(file_handle))  
        {  
            //--- file save error  
            printf("File save: Error %d!",GetLastError());  
            delete array;  
            FileClose(file_handle);  
            //---  
            return;  
        }  
        FileClose(file_handle);  
    }
```

```
    }  
    ///--- delete array  
    delete array;  
}
```

Load

Loads data array from the file.

```
virtual bool Load(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CArrayDouble::Load(int)  
#include <Arrays\ArrayDouble.mqh>  
//---  
void OnStart()  
{  
    int file_handle;  
    CArrayDouble *array=new CArrayDouble;  
    //---  
    if(array!=NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- open file  
    file_handle=FileOpen("MyFile.bin",FILE_READ|FILE_BIN|FILE_ANSI);  
    if(file_handle>=0)  
    {  
        if(!array.Load(file_handle))  
        {  
            //--- file load error  
            printf("File load: Error %d!",GetLastError());  
            delete array;  
            FileClose(file_handle);  
            //---  
            return;  
        }  
        FileClose(file_handle);  
    }  
    //--- use arrays elements  
    for(int i=0;i<array.Total();i++)  
    {  
        printf("Element[%d] = %f",i,array.At(i));  
    }  
}
```

```
    }  
    ///--- delete array  
    delete array;  
}
```

Type

Gets the array type identifier.

```
virtual int Type() const
```

Return Value

Array type identifier (for CArrayDouble - 87).

Example:

```
//--- example for CArrayDouble::Type()
#include <Arrays\ArrayDouble.mqh>
//---
void OnStart()
{
    CArrayDouble *array=new CArrayDouble;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- get array type
    int type=array.Type();
    //--- delete array
    delete array;
}
```

CArrayString

CArrayString class is a class of dynamic array of string variables.

Description

The CArrayString class provides the ability to work with a dynamic array of string variables. The class allows adding/inserting/deleting array elements, performing an array sorting, and searching in a sorted array. In addition, methods of working with files have been implemented.

Declaration

```
class CArrayString : public CArray
```

Title

```
#include <Arrays\ArrayString.mqh>
```

Inheritance hierarchy

[CObject](#)

[CArray](#)

CArrayString

Class Methods by Groups

Memory control	
Reserve	Allocates memory to increase the size of the array
Resize	Sets a new (smaller) size of the array
Shutdown	Clears the array with a full memory release
Add methods	
Add	Adds an element to the end of the array
AddArray	Adds elements of one array to the end of another
AddArray	Adds elements of one array to the end of another
Insert	Inserts an element to the specified position in the array
InsertArray	Inserts to an array elements from another array from the specified position
InsertArray	Inserts to an array elements from another array from the specified position
AssignArray	Copies the elements of one array to another

AssignArray	Copies the elements of one array to another
Update methods	
Update	Changes the element at the specified position array
Shift	Moves an item from a given position in the array to the specified offset
Delete methods	
Delete	Removes the element from the specified array position
DeleteRange	Deletes a group of elements from the specified array position
Access methods	
At	Gets the element from the specified array position
Compare methods	
CompareArray	Compares the array with another one
CompareArray	Compares the array with another one
Sorted array opetations	
InsertSort	Inserts an element in a sorted array
Search	Searches for an element equal to the sample in the sorted array
SearchGreat	Searches for an element with a value exceeding the value of the sample in the sorted array
SearchLess	Searches for an element with a value less than the value of the sample in the sorted array
SearchGreatOrEqual	Searches for an element with a value greater than or equal to the value of the sample in the sorted array
SearchLessOrEqual	Searches for an element with a value less than or equal to the value of the sample in the sorted array
SearchFirst	Searches for the first element equal to the sample in the sorted array
SearchLast	Searches for the last element equal to the sample in the sorted array
SearchLinear	Searches for the element equal to the sample in the array

Input/output	
virtual Save	Saves data array in the file
virtual Load	Loads data array from the file
virtual Type	Gets the type identifier of the array

Methods inherited from class CObject

Prev, Prev, Next, Next, [Compare](#)

Methods inherited from class CArray

[Step](#), [Step](#), [Total](#), [Available](#), [Max](#), [IsSorted](#), [SortMode](#), [Clear](#), [Sort](#)

Reserve

Allocates memory to increase the size of the array.

```
bool Reserve (
    int size      // number
)
```

Parameters

size

[in] The number of additional elements of the array.

Return Value

true - successful, false - there was an attempt to request for an amount less than or equal to zero, or failed to increase the array.

Note

To reduce fragmentation of memory, the array size is changed using the step previously determined by the Step(int) method or the default step of 16.

Example:

```
//--- example for CArrayString::Reserve(int)
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
{
    CArrayString *array=new CArrayString;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- reserve memory
    if(!array.Reserve(1024))
    {
        printf("Reserve error");
        delete array;
        return;
    }
    //--- use array
    //--- . . .
    //--- delete array
    delete array;
}
```

Resize

Sets a new (smaller) size of the array.

```
bool Resize(  
    int size      // size  
)
```

Parameters

size

[in] New size of the array.

Return Value

true - successful, false - there was an attempt to set the size less than or equal to zero.

Note

Changing the size of the array allows using the memory optimally. Excessive elements on the right are lost. To reduce fragmentation of memory, the array size is changed by the step previously determined by the Step(int) method or the default step of 16.

Example:

```
//--- example for CArrayString::Resize(int)  
#include <Arrays\ArrayString.mqh>  
//---  
void OnStart()  
{  
    CArrayString *array=new CArrayString;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- resize array  
    if(!array.Resize(10))  
    {  
        printf("Resize error");  
        delete array;  
        return;  
    }  
    //--- delete array  
    delete array;  
}
```

Shutdown

Clears the array with a full memory release.

```
bool Shutdown()
```

Return Value

true - successful, false - error.

Example:

```
//--- example for CArrayString::Shutdown()
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
{
    CArrayString *array=new CArrayString;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- . . .
    //--- shutdown array
    if(!array.Shutdown())
    {
        printf("Shutdown error");
        delete array;
        return;
    }
    //--- delete array
    delete array;
}
```

Add

Adds an element to the end of the array.

```
bool Add(  
    string element    // element to add  
)
```

Parameters

element

[in] Value of the element to add to the array.

Return Value

true - successful, false - cannot add an element.

Example:

```
///--- example for CArrayString::Add(string)  
#include <Arrays\ArrayString.mqh>  
///---  
void OnStart()  
{  
    CArrayString *array=new CArrayString;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    for(int i=0;i<100;i++)  
    {  
        if(!array.Add(IntegerToString(i)))  
        {  
            printf("Element addition error");  
            delete array;  
            return;  
        }  
    }  
    ///--- use array  
    ///--- . . .  
    ///--- delete array  
    delete array;  
}
```

AddArray

Adds elements of one array to the end of another.

```
bool AddArray(  
    const string& src[]      // source array  
)
```

Parameters

src[]

[in] Reference to an array of source elements to add.

Return Value

true - successful, false - cannot add items.

Example:

```
///--- example for CArrayString::AddArray(const string &[])  
#include <Arrays\ArrayString.mqh>  
///---  
string src[];  
///---  
void OnStart()  
{  
    CArrayString *array=new CArrayString;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add another array  
    if(!array.AddArray(src))  
    {  
        printf("Array addition error");  
        delete array;  
        return;  
    }  
    ///--- use array  
    ///--- . . .  
    ///--- delete array  
    delete array;  
}
```

AddArray

Adds elements of one array to the end of another.

```
bool AddArray(  
    const CArrayString* src      // pointer to the source  
)
```

Parameters

src

[in] Pointer to an instance of CArrayString class used as a source of elements to add.

Return Value

true - successful, false - cannot add items.

Example:

```
///--- example for CArrayString::AddArray(const CArrayString*)  
#include <Arrays\ArrayString.mqh>  
///---  
void OnStart()  
{  
    CArrayString *array=new CArrayString;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- create source array  
    CArrayString *src=new CArrayString;  
    if(src==NULL)  
    {  
        printf("Object create error");  
        delete array;  
        return;  
    }  
    ///--- add source arrays elements  
    ///--- . . .  
    ///--- add another array  
    if(!array.AddArray(src))  
    {  
        printf("Array addition error");  
        delete src;  
        delete array;  
        return;  
    }  
    ///--- delete source array  
    delete src;
```

```
//--- use array  
//--- . . .  
//--- delete array  
delete array;  
}
```

Insert

Inserts an element to the specified position in the array.

```
bool Insert(  
    string element,    // element to insert  
    int    pos         // position  
)
```

Parameters

element

[in] Value of the element to be inserted into an array

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert the element.

Example:

```
//--- example for CArrayString::Insert(string,int)  
#include <Arrays\ArrayString.mqh>  
//---  
void OnStart()  
{  
    CArrayString *array=new CArrayString;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- insert elements  
    for(int i=0;i<100;i++)  
    {  
        if(!array.Insert(IntegerToString(i),0))  
        {  
            printf("Insert error");  
            delete array;  
            return;  
        }  
    }  
    //--- use array  
    //--- . . .  
    //--- delete array  
    delete array;  
}
```

InsertArray

Inserts elements of one array from the specified position of another array.

```
bool InsertArray(  
    const string& src[],      // source array  
    int          pos         // position  
)
```

Parameters

src[]

[in] Reference to an array used as a source of elements to insert

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert items.

Example:

```
//--- example for CArrayString::InsertArray(const string &[],int)  
#include <Arrays\ArrayString.mqh>  
//---  
string src[];  
//---  
void OnStart()  
{  
    CArrayString *array=new CArrayString;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- insert another array  
    if(!array.InsertArray(src,0))  
    {  
        printf("Array inserting error");  
        delete array;  
        return;  
    }  
    //--- use array  
    //--- . . .  
    //--- delete array  
    delete array;  
}
```

InsertArray

Inserts elements of one array from the specified position of another array.

```
bool InsertArray(  
    CArrayString* src,      // pointer to the source  
    int          pos       // position  
)
```

Parameters

src

[in] Pointer to an instance of the CArrayString class used as a source of elements to insert.

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert items.

Example:

```
//--- example for CArrayString::InsertArray(const CArrayString*,int)  
#include <Arrays\ArrayString.mqh>  
//---  
void OnStart()  
{  
    CArrayString *array=new CArrayString;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- create source array  
    CArrayString *src=new CArrayString;  
    if(src==NULL)  
    {  
        printf("Object create error");  
        delete array;  
        return;  
    }  
    //--- add source arrays elements  
    //--- . . .  
    //--- insert another array  
    if(!array.InsertArray(src,0))  
    {  
        printf("Array inserting error");  
        delete src;  
        delete array;  
    }  
}
```

```
        return;  
    }  
    //--- delete source array  
    delete src;  
    //--- use array  
    //--- . . .  
    //--- delete array  
    delete array;  
}
```

AssignArray

Copies the elements of one array to another.

```
bool AssignArray(  
    const string& src[]      // source array  
)
```

Parameters

src[]

[in] Reference to an array used as a source of elements to copy.

Return Value

true - successful, false - cannot copy the items.

Example:

```
///--- example for CArrayString::AssignArray(const string &[])  
#include <Arrays\ArrayString.mqh>  
///---  
string src[];  
///---  
void OnStart()  
{  
    CArrayString *array=new CArrayString;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- assign another array  
    if(!array.AssignArray(src))  
    {  
        printf("Array assigned error");  
        delete array;  
        return;  
    }  
    ///--- use array  
    ///--- . . .  
    ///--- delete array  
    delete array;  
}
```

AssignArray

Copies the elements of one array to another.

```
bool AssignArray(  
    const CArrayString* src      // pointer to the source  
)
```

Parameters

src

[in] Pointer to an instance of the CArrayString class used as a source of elements to copy.

Return Value

true - successful, false - cannot copy the elements.

Example:

```
//--- example for CArrayString::AssignArray(const CArrayString*)  
#include <Arrays\ArrayString.mqh>  
//---  
void OnStart()  
{  
    CArrayString *array=new CArrayString;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- create source array  
    CArrayString *src =new CArrayString;  
    if(src==NULL)  
    {  
        printf("Object create error");  
        delete array;  
        return;  
    }  
    //--- add source arrays elements  
    //--- . . .  
    //--- assign another array  
    if(!array.AssignArray(src))  
    {  
        printf("Array assigned error");  
        delete src;  
        delete array;  
        return;  
    }  
    //--- arrays is identical  
    //--- delete source array
```

```
delete src;  
//--- use array  
//--- . . .  
//--- delete array  
delete array;  
}
```

Update

Changes the element at the specified array position.

```
bool Update(  
    int    pos,           // position  
    string element       // value  
)
```

Parameters

pos

[in] Position of the element in the array to change

element

[in] New value of the element

Return Value

true - successful, false - cannot change the element.

Example:

```
//--- example for CArrayString::Update(int, string)  
#include <Arrays\ArrayString.mqh>  
//---  
void OnStart()  
{  
    CArrayString *array=new CArrayString;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- update element  
    if(!array.Update(0,"ABC"))  
    {  
        printf("Update error");  
        delete array;  
        return;  
    }  
    //--- delete array  
    delete array;  
}
```

Shift

Moves an item from a given position in the array to the specified offset.

```
bool Shift(  
    int pos,          // position  
    int shift         // shift  
)
```

Parameters

pos

[in] Position of the moved element in the array

shift

[in] The shift value (both positive and negative).

Return Value

true - successful, false - cannot move the element.

Example:

```
//--- example for CArrayString::Shift(int,int)  
#include <Arrays\ArrayString.mqh>  
//---  
void OnStart()  
{  
    CArrayString *array=new CArrayString;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- shift element  
    if(!array.Shift(10,-5))  
    {  
        printf("Shift error");  
        delete array;  
        return;  
    }  
    //--- delete array  
    delete array;  
}
```

Delete

Removes the element from the specified array position.

```
bool Delete(  
    int pos    // position  
)
```

Parameters

pos

[in] Position of the array element to be removed.

Return Value

true - successful, false - cannot remove the element.

Example:

```
///--- example for CArrayString::Delete(int)  
#include <Arrays\ArrayString.mqh>  
///---  
void OnStart()  
{  
    CArrayString *array=new CArrayString;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- delete element  
    if(!array.Delete(0))  
    {  
        printf("Delete error");  
        delete array;  
        return;  
    }  
    ///--- delete array  
    delete array;  
}
```

DeleteRange

Deletes a group of elements from the specified array position.

```
bool DeleteRange(  
    int from,      // position of the first element  
    int to         // position of last element  
)
```

Parameters

from

[in] Position of the first array element to be removed.

to

[in] Position of the last array element to be removed.

Return Value

true - successful, false - cannot remove the elements.

Example:

```
//--- example for CArrayString::DeleteRange(int,int)  
#include <Arrays\ArrayString.mqh>  
//---  
void OnStart()  
{  
    CArrayString *array=new CArrayString;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- delete elements  
    if(!array.DeleteRange(0,10))  
    {  
        printf("Delete error");  
        delete array;  
        return;  
    }  
    //--- delete array  
    delete array;  
}
```

At

Gets the element from the specified array position.

```
string At(  
    int pos      // position  
    ) const
```

Parameters

pos

[in] Position of the desired element in the array.

Return Value

The value of the element - success, "" - there was an attempt to get an element from a non-existing position (the last error code is ERR_OUT_OF_RANGE).

Note

Of course, "" may be a valid value of an array element. Therefore, always check the last error code after receiving such a value.

Example:

```
///--- example for CArrayString::At(int)  
#include <Arrays\ArrayString.mqh>  
///---  
void OnStart()  
{  
    CArrayString *array=new CArrayString;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    for(int i=0;i<array.Total();i++)  
    {  
        string result=array.At(i);  
        if(result=="" && GetLastError()==ERR_OUT_OF_RANGE)  
        {  
            ///--- Error reading from array  
            printf("Get element error");  
            delete array;  
            return;  
        }  
        ///--- use element  
        ///--- . . .  
    }  
}
```

```
//--- delete array  
delete array;  
}
```

CompareArray

Compares the array with another one.

```
bool CompareArray(  
    const string& src[]      // source array  
    ) const
```

Parameters

src[]

[in] Reference to an array used as a source of elements for comparison.

Return Value

true - arrays are equal, false - arrays are not equal.

Example:

```
///--- example for CArrayString::CompareArray(const string &[])  
#include <Arrays\ArrayString.mqh>  
///---  
string src[];  
///---  
void OnStart()  
{  
    CArrayString *array=new CArrayString;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- compare with another array  
    int result=array.CompareArray(src);  
    ///--- delete array  
    delete array;  
}
```

CompareArray

Compares the array with another one.

```
bool CompareArrays (
    const CArrayString* src      // pointer to the source
) const
```

Parameters

src

[in] Pointer to an instance of the CArrayString class used as a source of elements for comparison.

Return Value

true - successful, false - cannot copy the items.

Example:

```
///--- example for CArrayString::CompareArray(const CArrayString*)
#include <Arrays\ArrayString.mqh>
///---
void OnStart ()
{
    CArrayString *array=new CArrayString;
    ///---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    ///--- create source array
    CArrayString *src=new CArrayString;
    if(src==NULL)
    {
        printf("Object create error");
        delete array;
        return;
    }
    ///--- add source arrays elements
    ///--- . . .
    ///--- compare with another array
    int result=array.CompareArray(src);
    ///--- delete arrays
    delete src;
    delete array;
}
```

InsertSort

Inserts an element in a sorted array.

```
bool InsertSort(  
    string element    // element to insert  
)
```

Parameters

element

[in] Value of the element to be inserted into a sorted array

Return Value

true - successful, false - cannot insert the element.

Example:

```
///--- example for CArrayString::InsertSort(string)  
#include <Arrays\ArrayString.mqh>  
///---  
void OnStart()  
{  
    CArrayString *array=new CArrayString;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- sort array  
    array.Sort();  
    ///--- insert element  
    if(!array.InsertSort("ABC"))  
    {  
        printf("Insert error");  
        delete array;  
        return;  
    }  
    ///--- delete array  
    delete array;  
}
```

Search

Searches for an element equal to the sample in the sorted array.

```
int Search(  
    string element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayString::Search(string)  
#include <Arrays\ArrayString.mqh>  
//---  
void OnStart()  
{  
    CArrayString *array=new CArrayString;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.Search("ABC")!=-1) printf("Element found");  
    else                        printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchGreat

Searches for an element with a value exceeding the value of the sample in the sorted array.

```
int SearchGreat(  
    string element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayString::SearchGreat(string)  
#include <Arrays\ArrayString.mqh>  
//---  
void OnStart()  
{  
    CArrayString *array=new CArrayString;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.SearchGreat("ABC")!= -1) printf("Element found");  
    else                             printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchLess

Searches for an element with a value less than the value of the sample in the sorted array.

```
int SearchLess(  
    string element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
///--- example for CArrayString:: SearchLess(string)  
#include <Arrays\ArrayString.mqh>  
///---  
void OnStart()  
{  
    CArrayString *array=new CArrayString;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- sort array  
    array.Sort();  
    ///--- search element  
    if(array.SearchLess("ABC")!=-1) printf("Element found");  
    else                          printf("Element not found");  
    ///--- delete array  
    delete array;  
}
```

SearchGreatOrEqual

Searches for an element with a value greater than or equal to the value of the sample in the sorted array.

```
int SearchGreatOrEqual(  
    string element    // sample  
) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
///--- example for CArrayString:: SearchGreatOrEqual(string)  
#include <Arrays\ArrayString.mqh>  
///---  
void OnStart()  
{  
    CArrayString *array=new CArrayString;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- sort array  
    array.Sort();  
    ///--- search element  
    if(array.SearchGreatOrEqual("ABC")!=-1) printf("Element found");  
    else                                     printf("Element not found");  
    ///--- delete array  
    delete array;  
}
```

SearchLessOrEqual

Searches for an element with a value less than or equal to the value of the sample in the sorted array.

```
int SearchLessOrEqual(  
    string element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
///--- example for CArrayString:: SearchLessOrEqual(string)  
#include <Arrays\ArrayString.mqh>  
///---  
void OnStart()  
{  
    CArrayString *array=new CArrayString;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- sort array  
    array.Sort();  
    ///--- search element  
    if(array.SearchLessOrEqual("ABC")!=-1) printf("Element found");  
    else                                printf("Element not found");  
    ///--- delete array  
    delete array;  
}
```

SearchFirst

Searches for the first element equal to the sample in the sorted array.

```
int SearchFirst(  
    string element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayString:: SearchFirst(string)  
#include <Arrays\ArrayString.mqh>  
//---  
void OnStart()  
{  
    CArrayString *array=new CArrayString;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- search element  
    if(array.SearchFirst("ABC")!= -1) printf("Element found");  
    else                             printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchLast

Searches for the last element equal to the sample in the sorted array.

```
int SearchLast(  
    string element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
///--- example for CArrayString:: SearchLast(string)  
#include <Arrays\ArrayString.mqh>  
///---  
void OnStart()  
{  
    CArrayString *array=new CArrayString;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- sort array  
    array.Sort();  
    ///--- search element  
    if(array.SearchLast("ABC")!= -1) printf("Element found");  
    else                             printf("Element not found");  
    ///--- delete array  
    delete array;  
}
```

SearchLinear

Searches for the element equal to the sample in the array.

```
int SearchLinear(  
    string element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Note

The method uses the linear search (or sequential search) algorithm for unsorted arrays.

Example:

```
///--- example for CArrayString::SearchLinear(string)  
#include <Arrays\ArrayString.mqh>  
///---  
void OnStart()  
{  
    CArrayString *array=new CArrayString;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- search element  
    if(array.SearchLinear("ABC")!=-1) printf("Element found");  
    else                             printf("Element not found");  
    ///--- delete array  
    delete array;  
}
```

Save

Saves data array in the file.

```
virtual bool Save(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CArrayString::Save(int)  
#include <Arrays\ArrayString.mqh>  
//---  
void OnStart()  
{  
    int file_handle;  
    CArrayString *array=new CArrayString;  
    //---  
    if(array!=NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add 100 arrays elements  
    for(int i=0;i<100;i++)  
    {  
        array.Add(IntegerToString(i));  
    }  
    //--- open file  
    file_handle=FileOpen("MyFile.bin",FILE_WRITE|FILE_BIN|FILE_ANSI);  
    if(file_handle>=0)  
    {  
        if(!array.Save(file_handle))  
        {  
            //--- file save error  
            printf("File save: Error %d!",GetLastError());  
            delete array;  
            FileClose(file_handle);  
            //---  
            return;  
        }  
        FileClose(file_handle);  
    }
```

```
    }  
    delete array;  
}
```

Load

Loads data array from the file.

```
virtual bool Load(
    int file_handle    // file handle
)
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CArrayString::Load(int)
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
{
    int file_handle;
    CArrayString *array=new CArrayString;
    //---
    if(array!=NULL)
    {
        printf("Object create error");
        return;
    }
    //--- open file
    file_handle=FileOpen("MyFile.bin",FILE_READ|FILE_BIN|FILE_ANSI);
    if(file_handle>=0)
    {
        if(!array.Load(file_handle))
        {
            //--- file load error
            printf("File load: Error %d!",GetLastError());
            delete array;
            FileClose(file_handle);
            //---
            return;
        }
        FileClose(file_handle);
    }
    //--- use arrays elements
    for(int i=0;i<array.Total();i++)
    {
        printf("Element[%d] = '%s'",i,array.At(i));
```

```
    }  
    delete array;  
}
```

Type

Gets the array type identifier.

```
virtual int Type() const
```

Return Value

Array type identifier (for CArrayString - 89).

Example:

```
//--- example for CArrayString::Type()
#include <Arrays\ArrayString.mqh>
//---
void OnStart()
{
    CArrayString *array=new CArrayString;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- get array type
    int type=array.Type();
    //--- delete array
    delete array;
}
```

CArrayObj

CArrayObj class is a class of dynamic array of pointers to instances of CObject and its derived classes.

Description

Class CArrayObj provides the ability to work with a dynamic array of pointers to instances of [CObject](#) and its derived classes. This allows working both with multidimensional dynamic arrays of primitive data types and with data structures that have more complex organization of data.

The class allows adding/inserting/deleting array elements, performing an array sorting, and searching in a sorted array. In addition, methods of working with files have been implemented.

There are certain [subtleties](#) of the class CArrayObj.

Declaration

```
class CArrayObj : public CArray
```

Title

```
#include <Arrays\ArrayObj.mqh>
```

Inheritance hierarchy

[CObject](#)

[CArray](#)

CArrayObj

Direct descendants

[CIndicators](#), [CSeries](#)

Class Methods by Groups

Attributes	
FreeMode	Gets the flag of memory management
FreeMode	Sets the flag of memory management
Memory control	
Reserve	Allocates memory to increase the size of the array
Resize	Sets a new (smaller) size of the array
Shutdown	Clears the array with full deallocation of its memory (but not its elements).
Creating a new element	
virtual CreateElement	Creates a new array element in the specified position

Add methods	
Add	Adds an element to the end of the array
AddArray	Adds an element to the end of the array
Insert	Inserts an element to the specified position in the array
InsertArray	Inserts to an array elements from another array from the specified position
AssignArray	Copies the elements of one array to another
Update methods	
Update	Changes the element at the specified position array
Shift	Moves an item from a given position in the array to the specified offset
Delete methods	
Detach	Gets the element from the specified position and removes it from the array
Delete	Removes the element from the specified array position
DeleteRange	Deletes a group of elements from the specified array position
Clear	Removes all elements of the array without the release of the array memory
Access methods	
At	Gets the element from the specified array position
Compare methods	
CompareArray	Compares the array with another one
Sorted array operations	
InsertSort	Inserts an element in a sorted array
Search	Searches for an element equal to the sample in the sorted array
SearchGreat	Searches for an element with a value exceeding the value of the sample in the sorted array
SearchLess	Searches for an element with a value less than the value of the sample in the sorted array
SearchGreatOrEqual	Searches for an element with a value greater than or equal to the value of the sample in the

	sorted array
SearchLessOrEqual	Searches for an element with a value less than or equal to the value of the sample in the sorted array
SearchFirst	Searches for the first element equal to the sample in the sorted array
SearchLast	Searches for the last element equal to the sample in the sorted array
Input/output	
Save	Saves data array in the file
Load	Loads data array from the file
Type	Gets the type identifier of the array

Methods inherited from class CObject

Methods inherited from class CArray

[Step](#), [Step](#), [Total](#), [Available](#), [Max](#), [IsSorted](#), [SortMode](#), [Clear](#), [Sort](#)

Arrays of the CObject class have practical application (including all classes of the Standard Library).

For example, consider the options for two-dimensional array:

```
#include <Arrays\ArrayDouble.mqh>
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
{
    int i,j;
    int first_size=10;
    int second_size=100;
    //--- create array
    CArrayObj *array=new CArrayObj;
    CArrayDouble *sub_array;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- create subarrays
    for(i=0;i<first_size;i++)
    {
        sub_array=new CArrayDouble;
        if(sub_array==NULL)
```

```

    {
        delete array;
        printf("Object create error");
        return;
    }
    //--- fill array
    for(j=0;j<second_size;j++)
    {
        sub_array.Add(i*j);
    }
    array.Add(sub_array);
}
//--- create array OK
for(i=0;i<first_size;i++)
{
    sub_array=array.At(i);
    for(j=0;j<second_size;j++)
    {
        double element=sub_array.At(j);
        //--- use array element
    }
}
delete array;
}

```

Subtleties

The class has a mechanism to control dynamic memory, so be careful when working with elements of the array.

Mechanism of memory management can be switched on/off using the method FreeMode (bool). By default, the mechanism is enabled.

Accordingly, there are two options for dealing with the CArrayObj class:

1. Mechanism of memory management is enabled. (default)

In this case, CArrayObj takes responsibility for releasing the memory used for the elements after their removal from the array. A custom program should not release the array elements.

Example:

```

int i;
//--- create an array
CArrayObj *array=new CArrayObj;
//--- fill array elements
for(i=0;i<10;i++) array.Add(new CObject);
//--- do something
for(i=0;i<array.Total();i++)
{

```

```
    CObject *object=array.At(i);  
    //--- actions performed with the element  
    . . .  
}  
//--- remove the array with the elements  
delete array;
```

2. Mechanism of memory management is disabled.

In this case, CArrayObj is not responsible for deallocating of the elements' memory after their removal from the array. Besides, the user program must deallocate the array elements.

Example:

```
int i;  
//--- create an array  
CArrayObj *array=new CArrayObj;  
//--- disable the mechanism of memory management  
array.FreeMode(false);  
//--- fill array with elements  
for(i=0;i<10;i++) array.Add(new CObject);  
//--- do something  
for(i=0;i<array.Total();i++)  
{  
    CObject *object=array.At(i);  
    //--- actions performed with the element  
    . . .  
}  
//--- remove array elements  
while(array.Total()) delete array.Detach();  
//--- remove empty array  
delete array;
```

FreeMode

Gets the flag of memory management.

```
bool FreeMode() const
```

Return Value

Flag of memory management.

Example:

```
//--- example for CArrayObj::FreeMode()
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
{
    CArrayObj *array=new CArrayObj;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- get free mode flag
    bool array_free_mode=array.FreeMode();
    //--- delete array
    delete array;
}
```

FreeMode

Sets the flag of memory management.

```
void FreeMode(  
    bool mode    // new flag  
)
```

Parameters

mode

[in] New value of the memory management flag.

Return Value

None.

Note

Setting the memory management flag is an important part in the CArrayObj class use. Since the array elements are pointers to dynamic objects, it is important to determine what to do with them when removing from the array.

If the flag is set, removing an element from the array, the element is automatically deleted by the delete operator. If the flag is not set, it is assumed that a pointer to the deleted object is still somewhere in the user program and will be deallocated by the program afterwards.

If the user program resets the flag of memory management, the user must understand his responsibility for the removal of the array before the termination of the program. Otherwise the memory allocated for elements by the new operator is not released.

For large amounts of data this could lead even to crash of your terminal.

If the user does not reset the memory management flag, there is another pitfall. When pointer elements in array are stored somewhere in the local variables, then removing the array will lead to a critical error and crash of the user program. By default, the memory management flag is set, i.e. the class of the array is responsible for freeing the memory elements.

Example:

```
//--- example for CArrayObj::FreeMode(bool)  
#include <Arrays\ArrayObj.mqh>  
//---  
void OnStart()  
{  
    CArrayObj *array=new CArrayObj;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- reset free mode flag  
    array.FreeMode(false);
```

```
//--- use array  
//--- . . .  
//--- delete array  
delete array;  
}
```

Reserve

Allocates memory to increase the size of the array.

```
bool Reserve (
    int size      // number
)
```

Parameters

size

[in] The number of additional elements of the array.

Return Value

true - successful, false - there was an attempt to request for an amount less than or equal to zero, or failed to increase the array.

Note

To reduce fragmentation of memory, the array size is changed using the step previously determined by the Step(int) method or the default step of 16.

Example:

```
///--- example for CArrayObj::Reserve(int)
#include <Arrays\ArrayObj.mqh>
///---
void OnStart()
{
    CArrayObj *array=new CArrayObj;
    ///---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    if(!array.Reserve(1024))
    {
        printf("Reserve error");
        delete array;
        return;
    }
    ///--- use array
    ///--- . . .
    ///--- delete array
    delete array;
}
```

Resize

Sets a new (smaller) size of the array.

```
bool Resize(  
    int size    // size  
)
```

Parameters

size

[in] New size of the array.

Return Value

true - successful, false - there was an attempt to set the size less than or equal to zero.

Note

Changing the size of the array allows using the memory optimally. Excessive elements on the right are lost. The memory of the lost elements is released or not depending on the memory management mode.

To reduce fragmentation of memory, change the size of the array is made with a step previously given through the method of Step (int), or 16 (default).

Example:

```
///--- example for CArrayObj::Resize(int)  
#include <Arrays\ArrayObj.mqh>  
///---  
void OnStart()  
{  
    CArrayObj *array=new CArrayObj;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- resize array  
    if(!array.Resize(10))  
    {  
        printf("Resize error");  
        delete array;  
        return;  
    }  
    ///--- delete array  
    delete array;  
}
```

Clear

Removes all elements of the array without the release of the memory array.

```
void Clear()
```

Return Value

No.

Note

If the memory management flag is enabled, the memory used for the deleted objects is released.

Example:

```
//--- example for CArrayObj::Clear()
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
{
    CArrayObj *array=new CArrayObj;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- . . .
    //--- clear array
    array.Clear();
    //--- delete array
    delete array;
}
```

Shutdown

Clears the array with full deallocation of memory for it (but not for its elements).

```
bool Shutdown()
```

Return Value

true - successful, false - an error occurred.

Note

If memory management is enabled, the memory of deleted elements is deallocated.

Example:

```
//--- example for CArrayObj::Shutdown()
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
{
    CArrayObj *array=new CArrayObj;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add arrays elements
    //--- . . .
    //--- shutdown array
    if(!array.Shutdown())
    {
        printf("Shutdown error");
        delete array;
        return;
    }
    //--- delete array
    delete array;
}
```

CreateElement

Creates a new array element at the specified position.

```
bool CreateElement(  
    int index    // position  
)
```

Parameters

index

[in] Position in which you want to create a new element.

Return Value

true - successful, false - cannot create an element.

Note

Method CreateElement (int) in class CArrayObj always returns false and does not perform any action. If necessary, the CreateElement(int) method should be implemented in a derived class.

Example:

```
///--- example for CArrayObj::CreateElement(int)  
#include <Arrays\ArrayObj.mqh>  
///---  
void OnStart()  
{  
    int size=100;  
    CArrayObj *array=new CArrayObj;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- fill array  
    array.Reserve(size);  
    for(int i=0;i<size;i++)  
    {  
        if(!array.CreateElement(i))  
        {  
            printf("Element create error");  
            delete array;  
            return;  
        }  
    }  
    ///--- use array  
    ///--- . . .  
    ///--- delete array  
    delete array;
```

```
}
```

Add

Adds an element to the end of the array.

```
bool Add(  
    CObject* element    // element to add  
)
```

Parameters

element

[in] value of the element to add to the array.

Return Value

true - successful, false - cannot add an element.

Note

Element is not added to the array if an invalid pointer (such as NULL) is passed as a parameter.

Example:

```
///--- example for CArrayObj::Add(CObject*)  
#include <Arrays\ArrayObj.mqh>  
///---  
void OnStart()  
{  
    CArrayObj *array=new CArrayObj;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add 100 arrays elements  
    for(int i=0;i<100;i++)  
    {  
        if(!array.Add(new CObject))  
        {  
            printf("Element addition error");  
            delete array;  
            return;  
        }  
    }  
    ///--- use array  
    ///--- . . .  
    ///--- delete array  
    delete array;  
}
```

AddArray

Adds elements from one array to the end of another.

```
bool AddArray(  
    const CArrayObj * src      // pointer to the source array  
)
```

Parameters

src

[in] Pointer to an instance of the [CArrayDouble](#) class - source of elements to add.

Return Value

true - successful, false - cannot add items.

Note

Adding elements from array to array is actually copying the pointers. Therefore, when calling the method, there is a pitfall - there may be a pointer to a dynamic object in more than one variable.

```
//--- example  
extern bool      make_error;  
extern int       error;  
extern CArrayObj *src;  
//--- create a new instance CArrayObj  
//--- default memory management is turned on  
CArrayObj *array=new CArrayObj;  
//--- add (copy) the elements from the source array  
if(array!=NULL)  
    bool result=array.AddArray(src);  
if(make_error)  
{  
    //--- perform erroneous actions  
    switch(error)  
    {  
        case 0:  
            //--- remove the source array without checking its memory management flag  
            delete src;  
            //--- result:  
            //--- it is possible to address an element by invalid pointer in the receiver  
            break;  
        case 1:  
            //--- disable the mechanism of memory management in the source array  
            if(src.FreeMode()) src.FreeMode(false);  
            //--- but do not remove the source array  
            //--- result:  
            //--- after removing the receiver array, it is possible to address an element  
            break;  
        case 2:
```

```

        //--- disable the mechanism of memory management in the source array
        src.FreeMode(false);
        //--- disable the mechanism of memory management in the receiver array
        array.FreeMode(false);
        //--- result:
        //--- after the program termination, get a "memory leak"
        break;
    }
}
else
{
    //--- disable the mechanism of memory management in the source array
    if(src.FreeMode()) src.FreeMode(false);
    //--- delete the source array
    delete src;
    //--- result:
    //--- addressing the receiver array element will be correct
    //--- deleting the receiver array will lead to deleting its elements
}

```

Example:

```

//--- example for CArrayObj::AddArray(const CArrayObj*)
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
{
    CArrayObj *array=new CArrayObj;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- create source array
    CArrayObj *src=new CArrayObj;
    if(src==NULL)
    {
        printf("Object create error");
        delete array;
        return;
    }
    //--- reset free mode flag
    src.FreeMode(false);
    //--- fill source array
    //--- . . .
    //--- add another array
    if(!array.AddArray(src))

```

```
{  
    printf("Array addition error");  
    delete src;  
    delete array;  
    return;  
}  
//--- delete source array without elements  
delete src;  
//--- use array  
//--- . . .  
//--- delete array  
delete array;  
}
```

Insert

Inserts an element to the specified position in the array.

```
bool Insert(  
    CObject* element,    // element to insert  
    int      pos         // position  
)
```

Parameters

element

[in] Value of the element to be inserted into an array

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert the element.

Note

Element is not added to the array if an invalid pointer (such as NULL) is passed as a parameter.

Example:

```
//--- example for CArrayObj::Insert(CObject*,int)  
#include <Arrays\ArrayObj.mqh>  
//---  
void OnStart()  
{  
    CArrayObj *array=new CArrayObj;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- insert elements  
    for(int i=0;i<100;i++)  
    {  
        if(!array.Insert(new CObject,0))  
        {  
            printf("Insert error");  
            delete array;  
            return;  
        }  
    }  
    //--- use array  
    //--- . . .  
    //--- delete array
```

```
delete array;  
}
```

InsertArray

Inserts elements of one array from the specified position of another array.

```
bool InsertArray(  
    const CArrayObj* src,      // pointer to the source  
    int pos                   // position  
)
```

Parameters

src

[in] Pointer to an instance of the CArrayObj class used as a source of elements to insert.

pos

[in] Position in the array to insert

Return Value

true - successful, false - cannot insert items.

Note

See: [CArrayObj::AddArray\(const CArrayObj*\)](#).

Example:

```
//--- example for CArrayObj::InsertArray(const CArrayObj*,int)  
#include <Arrays\ArrayObj.mqh>  
//---  
void OnStart()  
{  
    CArrayObj *array=new CArrayObj;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- create source array  
    CArrayObj *src=new CArrayObj;  
    if(src==NULL)  
    {  
        printf("Object create error");  
        delete array;  
        return;  
    }  
    //--- reset free mode flag  
    src.FreeMode(false);  
    //--- fill source array  
    //--- . . .  
    //--- insert another array
```

```
if(!array.InsertArray(src,0))
{
    printf("Array inserting error");
    delete src;
    delete array;
    return;
}
//--- delete source array without elements
delete src;
//--- use array
//--- . . .
//--- delete array
delete array;
}
```

AssignArray

Compares the array with another one.

```
bool AssignArray(  
    const CArrayObj* src      // pointer to the source  
)
```

Parameters

src

[in] Pointer to an instance of the CArrayObj class used as a source of elements to copy.

Return Value

true - successful, false - cannot copy the elements.

Note

If the receiver array is not empty when calling AssignArray, then all its elements will be removed; and if the memory management flag is set, the memory used for the deleted elements will be released. The receiver array becomes an exact copy of the source one. Additionally, see [CArrayObj::AddArray\(const CArrayObj*\)](#).

Example:

```
//--- example for CArrayObj::AssignArray(const CArrayObj*)  
#include <Arrays\ArrayObj.mqh>  
//---  
void OnStart()  
{  
    CArrayObj *array=new CArrayObj;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- create source array  
    CArrayObj *src=new CArrayObj;  
    if(src==NULL)  
    {  
        printf("Object create error");  
        delete array;  
        return;  
    }  
    //--- reset free mode flag  
    src.FreeMode(false);  
    //--- fill source array  
    //--- . . .  
    //--- assign another array  
    if(!array.AssignArray(src))
```

```
{
    printf("Array assigned error");
    delete src;
    delete array;
    return;
}

//--- arrays is identical
//--- delete source array without elements
delete src;
//--- use array
//--- . . .
//--- delete array
delete array;
}
```

Update

Changes the element at the specified array position.

```
bool Update(  
    int      pos,          // position  
    CObject* element       // value  
)
```

Parameters

pos

[in] Position of the element in the array to change

element

[in] New value of the element

Return Value

true - successful, false - cannot change the element.

Note

The element will not change if an invalid pointer (for example, NULL) is passed as a parameter. If the memory management is enabled, the memory of a replaced element is deallocated.

Example:

```
//--- example for CArrayObj::Update(int,CObject*)  
#include <Arrays\ArrayObj.mqh>  
//---  
void OnStart()  
{  
    CArrayObj *array=new CArrayObj;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- update element  
    if(!array.Update(0,new CObject))  
    {  
        printf("Update error");  
        delete array;  
        return;  
    }  
    //--- delete array  
    delete array;  
}
```

Shift

Moves an item from a given position in the array to the specified offset.

```
bool Shift(  
    int pos,          // position  
    int shift         // shift  
)
```

Parameters

pos

[in] Position of the moved element in the array

shift

[in] The shift value (both positive and negative).

Return Value

true - successful, false - cannot move the element.

Example:

```
//--- example for CArrayObj::Shift(int,int)  
#include <Arrays\ArrayObj.mqh>  
//---  
void OnStart()  
{  
    CArrayObj *array=new CArrayObj;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- shift element  
    if(!array.Shift(10,-5))  
    {  
        printf("Shift error");  
        delete array;  
        return;  
    }  
    //--- delete array  
    delete array;  
}
```

Detach

Removes an element from a given position in the array.

```
CObject* Detach(  
    int pos    // position  
)
```

Parameters

pos

[in] Position of a removed item in the array.

Return Value

Pointer to the removed element - success, NULL - cannot remove the element.

Note

When an element is removed from the array, it will not be deleted regardless of the memory management flag. Once the array element pointer is used, it has to be deallocated.

Example:

```
//--- example for CArrayObj::Detach(int)  
#include <Arrays\ArrayObj.mqh>  
//---  
void OnStart()  
{  
    CArrayObj *array=new CArrayObj;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    CObject *object=array.Detach(0);  
    if(object==NULL)  
    {  
        printf("Detach error");  
        delete array;  
        return;  
    }  
    //--- use element  
    //--- . . .  
    //--- delete element  
    delete object;  
    //--- delete array  
    delete array;  
}
```

Delete

Removes the element from the specified array position.

```
bool Delete(  
    int pos    // position  
)
```

Parameters

pos

[in] Position of the array element to be removed.

Return Value

true - successful, false - cannot remove the element.

Note

If the memory management is enabled, the memory of deleted elements is deallocated.

Example:

```
///--- example for CArrayObj::Delete(int)  
#include <Arrays\ArrayObj.mqh>  
///---  
void OnStart()  
{  
    CArrayObj *array=new CArrayObj;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    if(!array.Delete(0))  
    {  
        printf("Delete error");  
        delete array;  
        return;  
    }  
    ///--- delete array  
    delete array;  
}
```

DeleteRange

Deletes a group of elements from the specified array position.

```
bool DeleteRange(  
    int from,      // position of the first element  
    int to         // position of last element  
)
```

Parameters

from

[in] Position of the first array element to be removed.

to

[in] Position of the last array element to be removed.

Return Value

true - successful, false - cannot remove elements.

Note

If the memory management is enabled, the memory of deleted elements is deallocated.

Example:

```
///--- example for CArrayObj::DeleteRange(int,int)  
#include <Arrays\ArrayObj.mqh>  
///---  
void OnStart()  
{  
    CArrayObj *array=new CArrayObj;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- delete elements  
    if(!array.DeleteRange(0,10))  
    {  
        printf("Delete error");  
        delete array;  
        return;  
    }  
    ///--- delete array  
    delete array;  
}
```

At

Gets the element from the specified array position.

```
CObject* At(  
    int pos    // position  
)
```

Parameters

pos

[in] Position of the desired element in the array.

Return Value

The value of the element - successful, NULL- there was an attempt to get an element of a non-existent position.

Example:

```
///--- example for CArrayObj::At(int)  
#include <Arrays\ArrayObj.mqh>  
///---  
void OnStart()  
{  
    CArrayObj *array=new CArrayObj;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add elements  
    ///--- . . .  
    for(int i=0;i<array.Total();i++)  
    {  
        CObject *result=array.At(i);  
        if(result==NULL)  
        {  
            ///--- Error reading from array  
            printf("Get element error");  
            delete array;  
            return;  
        }  
        ///--- use element  
        ///--- . . .  
    }  
    delete array;  
}
```

CompareArray

Compares the array with another one.

```
bool CompareArray(  
    const CArrayObj* src      // pointer to the source  
    ) const
```

Parameters

src

[in] Pointer to an instance of the CArrayObj class used as a source of elements for comparison.

Return Value

true - the arrays are equal - the arrays are not equal.

Example:

```
///--- example for CArrayObj::CompareArray(const CArrayObj*)  
#include <Arrays\ArrayObj.mqh>  
///---  
void OnStart()  
{  
    CArrayObj *array=new CArrayObj;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- create source array  
    CArrayObj *src=new CArrayObj;  
    if(src==NULL)  
    {  
        printf("Object create error");  
        delete array;  
        return;  
    }  
    ///--- fill source array  
    ///--- . . .  
    ///--- compare with another array  
    int result=array.CompareArray(src);  
    ///--- delete arrays  
    delete src;  
    delete array;  
}
```

InsertSort

Inserts an element in a sorted array.

```
bool InsertSort(  
    CObject* element    // element to insert  
)
```

Parameters

element

[in] Value of the element to be inserted into a sorted array

Return Value

true - successful, false - cannot insert the element.

Note

Element is not added to the array if an invalid pointer (such as NULL) is passed as a parameter.

Example:

```
///--- example for CArrayObj::InsertSort(CObject*)  
#include <Arrays\ArrayObj.mqh>  
///---  
void OnStart()  
{  
    CArrayObj *array=new CArrayObj;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- sort array  
    array.Sort();  
    ///--- insert element  
    if(!array.InsertSort(new CObject))  
    {  
        printf("Insert error");  
        delete array;  
        return;  
    }  
    ///--- delete array  
    delete array;  
}
```

Search

Searches for an element equal to the sample in the sorted array.

```
int Search(  
    CObject* element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayObj::Search(CObject*)  
#include <Arrays\ArrayObj.mqh>  
//---  
void OnStart()  
{  
    CArrayObj *array=new CArrayObj;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- create sample  
    CObject *sample=new CObject;  
    if(sample==NULL)  
    {  
        printf("Sample create error");  
        delete array;  
        return;  
    }  
    //--- set sample attributes  
    //--- . . .  
    //--- search element  
    if(array.Search(sample)!=-1) printf("Element found");  
    else                        printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

SearchGreat

Searches for an element with a value exceeding the value of the sample in the sorted array.

```
int SearchGreat(  
    CObject* element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
///--- example for CArrayObj::SearchGreat(CObject*)  
#include <Arrays\ArrayObj.mqh>  
///---  
void OnStart()  
{  
    CArrayObj *array=new CArrayObj;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- sort array  
    array.Sort();  
    ///--- create sample  
    CObject *sample=new CObject;  
    if(sample==NULL)  
    {  
        printf("Sample create error");  
        delete array;  
        return;  
    }  
    ///--- set sample attributes  
    ///--- . . .  
    ///--- search element  
    if(array.SearchGreat(sample)!=-1) printf("Element found");  
    else                             printf("Element not found");  
    ///--- delete array  
    delete array;  
}
```

SearchLess

Searches for an element with a value less than the value of the sample in the sorted array.

```
int SearchLess(  
    CObject* element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
///--- example for CArrayObj:: SearchLess(CObject*)  
#include <Arrays\ArrayObj.mqh>  
///---  
void OnStart()  
{  
    CArrayObj *array=new CArrayObj;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- sort array  
    array.Sort();  
    ///--- create sample  
    CObject *sample=new CObject;  
    if(sample==NULL)  
    {  
        printf("Sample create error");  
        delete array;  
        return;  
    }  
    ///--- set sample attributes  
    ///--- . . .  
    ///--- search element  
    if(array.SearchLess(sample)!=-1) printf("Element found");  
    else                             printf("Element not found");  
    ///--- delete array  
    delete array;  
}
```

SearchGreatOrEqual

Searches for an element with a value greater than or equal to the value of the sample in the sorted array.

```
int SearchGreatOrEqual(  
    CObject* element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayObj::SearchGreatOrEqual(CObject*)  
#include <Arrays\ArrayObj.mqh>  
//---  
void OnStart()  
{  
    CArrayObj *array=new CArrayObj;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- create sample  
    CObject *sample=new CObject;  
    if(sample==NULL)  
    {  
        printf("Sample create error");  
        delete array;  
        return;  
    }  
    //--- set sample attributes  
    //--- . . .  
    //--- search element  
    if(array.SearchGreatOrEqual(sample)!=-1) printf("Element found");  
    else                                     printf("Element not found");  
    //--- delete array  
    delete array;
```

```
}
```

SearchLessOrEqual

Searches for an element with a value less than or equal to the value of the sample in the sorted array.

```
int SearchLessOrEqual(  
    CObject* element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
///--- example for CArrayObj:: SearchLessOrEqual(CObject*)  
#include <Arrays\ArrayObj.mqh>  
///---  
void OnStart()  
{  
    CArrayObj *array=new CArrayObj;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- sort array  
    array.Sort();  
    ///--- create sample  
    CObject *sample=new CObject;  
    if(sample==NULL)  
    {  
        printf("Sample create error");  
        delete array;  
        return;  
    }  
    ///--- set sample attributes  
    ///--- . . .  
    ///--- search element  
    if(array.SearchLessOrEqual(sample)!=-1) printf("Element found");  
    else                                  printf("Element not found");  
    ///--- delete array  
    delete array;  
}
```

SearchFirst

Searches for the first element equal to the sample in the sorted array.

```
int SearchFirst(  
    CObject* element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
///--- example for CArrayObj::SearchFirst(CObject*)  
#include <Arrays\ArrayObj.mqh>  
///---  
void OnStart()  
{  
    CArrayObj *array=new CArrayObj;  
    ///---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add arrays elements  
    ///--- . . .  
    ///--- sort array  
    array.Sort();  
    ///--- create sample  
    CObject *sample=new CObject;  
    if(sample==NULL)  
    {  
        printf("Sample create error");  
        delete array;  
        return;  
    }  
    ///--- set sample attributes  
    ///--- . . .  
    ///--- search element  
    if(array.SearchFirst(sample)!=-1) printf("Element found");  
    else                             printf("Element not found");  
    ///--- delete array  
    delete array;  
}
```

SearchLast

Searches for the last element equal to the sample in the sorted array.

```
int SearchLast(  
    CObject* element    // sample  
    ) const
```

Parameters

element

[in] The sample element to search in the array.

Return Value

The position of the found element - successful, -1 - the element not found.

Example:

```
//--- example for CArrayObj:: SearchLast(CObject*)  
#include <Arrays\ArrayObj.mqh>  
//---  
void OnStart()  
{  
    CArrayObj *array=new CArrayObj;  
    //---  
    if(array==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- sort array  
    array.Sort();  
    //--- create sample  
    CObject *sample=new CObject;  
    if(sample==NULL)  
    {  
        printf("Sample create error");  
        delete array;  
        return;  
    }  
    //--- set sample attributes  
    //--- . . .  
    //--- search element  
    if(array.SearchLast(sample)!=-1) printf("Element found");  
    else                             printf("Element not found");  
    //--- delete array  
    delete array;  
}
```

Save

Saves data array in the file.

```
virtual bool Save(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CArrayObj::Save(int)  
#include <Arrays\ArrayObj.mqh>  
//---  
void OnStart()  
{  
    int file_handle;  
    CArrayObj *array=new CArrayObj;  
    //---  
    if(array!=NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add arrays elements  
    //--- . . .  
    //--- open file  
    file_handle=FileOpen("MyFile.bin",FILE_WRITE|FILE_BIN|FILE_ANSI);  
    if(file_handle>=0)  
    {  
        if(!array.Save(file_handle))  
        {  
            //--- file save error  
            printf("File save: Error %d!",GetLastError());  
            delete array;  
            FileClose(file_handle);  
            //---  
            return;  
        }  
        FileClose(file_handle);  
    }  
    delete array;  
}
```

Load

Loads data array from the file.

```
virtual bool Load(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen(...) function.

Return Value

true - successfully completed, false - error.

Note

When reading array elements from the file, the [CArrayObj::CreateElement\(int\)](#) method is called to create each element.

Example:

```
//--- example for CArrayObj::Load(int)  
#include <Arrays\ArrayObj.mqh>  
//---  
void OnStart()  
{  
    int file_handle;  
    CArrayObj *array=new CArrayObj;  
    //---  
    if(array!=NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- open file  
    file_handle=FileOpen("MyFile.bin",FILE_READ|FILE_BIN|FILE_ANSI);  
    if(file_handle>=0)  
    {  
        if(!array.Load(file_handle))  
        {  
            //--- file load error  
            printf("File load: Error %d!",GetLastError());  
            delete array;  
            FileClose(file_handle);  
            //---  
            return;  
        }  
        FileClose(file_handle);  
    }  
}
```

```
//--- use arrays elements  
//--- . . .  
//--- delete array  
delete array;  
}
```

Type

Gets the array type identifier.

```
virtual int Type() const
```

Return Value

Array type identifier (for CArrayObj - 7778).

Example:

```
//--- example for CArrayObj::Type()
#include <Arrays\ArrayObj.mqh>
//---
void OnStart()
{
    CArrayObj *array=new CArrayObj;
    //---
    if(array==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- get array type
    int type=array.Type();
    //--- delete array
    delete array;
}
```

CList

CList Class is a class of dynamic list of instances of the CObject class and its derived classes.

Description

Class CList provides the ability to work with a list of instances of [CObject](#) and its derived classes. The class allows adding/inserting/deleting array elements, performing an array sorting, and searching in a sorted array. In addition, methods of working with files have been implemented.

There are some subtleties of working with the CList class. The class has a mechanism to control dynamic memory, so be careful when working with elements of the list.

[Subtleties](#) of the mechanism of memory management similar to those described in CArrayObj.

Declaration

```
class CList : public CObject
```

Title

```
#include <Arrays\List.mqh>
```

Inheritance hierarchy

[CObject](#)

CList

Class Methods by Groups

Attributes	
FreeMode	Gets the flag of memory management when deleting list elements
FreeMode	Sets the flag of memory management when deleting list elements
Total	Gets the number of elements in the list
IsSorted	Gets sorted list flag
SortMode	Gets the sorting mode
Create methods	
CreateElement	Creates a new list element
Add methods	
Add	Adds an element to the end of the list
Insert	Inserts an element to the specified position of the list

Delete methods	
DetachCurrent	Removes an element from the current position in the list without deleting it "physically"
DeleteCurrent	Removes the element from the current position in the list
Delete	Removes the element from the specified position in the list
Clear	Removes all list elements
Navigation	
IndexOf	Gets the index of the specified list element
GetNodeAtIndex	Gets an item with the specified index of the list
GetFirstNode	Gets the first element of the list
GetPrevNode	Gets the previous element of the list
GetCurrentNode	Gets the current list element
GetNextNode	Gets the next element in the list
GetLastNode	Gets the last element in the list
Ordering methods	
Sort	Sorts the list
MoveToIndex	Moves the current element in the list to the specified position
Exchange	Swaps two elements in the list
Compare methods	
CompareList	Compares the list with another one
Search methods	
Search	Searches for an element equal to the sample in sorted list
Input/output	
virtual Save	Saves list data in the file
virtual Load	Loads list data from the file
virtual Type	Gets the list type identifier

Methods inherited from class CObject

Prev, Prev, Next, Next, [Compare](#)

FreeMode

Gets the flag of memory management when deleting list elements.

```
bool FreeMode() const
```

Return Value

Flag of memory management.

Example:

```
//--- example for CList::FreeMode()
#include <Arrays\List.mqh>
//---
void OnStart()
{
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- get free mode flag
    bool list_free_mode=list.FreeMode();
    //--- delete list
    delete list;
}
```

FreeMode

Sets the flag of memory management when deleting list elements.

```
void FreeMode(  
    bool mode    // new value  
)
```

Parameters

mode

[in] New value of the memory management flag.

Note

Setting the memory management flag is an important part in the CList class use. Since the list elements are pointers to dynamic objects, it is important to determine what to do with them when removing from the list.

If the flag is set, when removing an element from the list, the element is automatically deleted by the delete operator. If the flag is not set, it is assumed that a pointer to the deleted object is still somewhere in the user program and will be deallocated by the program afterwards.

If the user program resets the flag of memory management, users should understand their responsibility for the removal of the list elements before the termination of the program. Otherwise, the memory allocated for elements by the new operator is not released.

For large amounts of data this could lead even to a terminal crash.

If the user program does not reset the memory management flag, there is another "pitfall". When pointer elements in list are stored somewhere in the local variables, then removing the list will lead to a critical error and crash of the user program. By default, the memory management flag is set, i.e. the class of the list is responsible for releasing the memory elements.

Example:

```
//--- example for CList::FreeMode(bool)  
#include <Arrays\List.mqh>  
//---  
void OnStart()  
{  
    CList *list=new CList;  
    //---  
    if(list==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- reset free mode flag  
    list.FreeMode(false);  
    //--- use list  
    //--- . . .  
    //--- delete list
```

```
delete list;  
}
```

Total

Gets the number of elements in the list.

```
int Total() const
```

Return Value

Number of elements in the list.

Example:

```
//--- example for CList::Total()
#include <Arrays\List.mqh>
//---
void OnStart()
{
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- check total
    int total=list.Total();
    //--- use list
    //--- ...
    //--- delete list
    delete list;
}
```

IsSorted

Gets the sorted list flag.

```
bool IsSorted(  
    int mode=0      // sorting mode  
) const
```

Parameters

mode=0

[in] Checked sort mode.

Return Value

Flag of the sorted list. Returns true if the list is sorted using the specified mode, otherwise returns false.

Note

Flag of the sorted list cannot be changed directly. The flag is set by Sort(int) and resets by any add/insert methods.

Example:

```
///--- example for CList::IsSorted()  
#include <Arrays\List.mqh>  
///---  
void OnStart()  
{  
    CList *list=new CList;  
    ///---  
    if(list==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- check sorted  
    if(list.IsSorted(0))  
    {  
        ///--- use methods for sorted list  
        ///--- ...  
    }  
    ///--- delete list  
    delete list;  
}
```

SortMode

Gets the version of the sorting.

```
int SortMode() const
```

Return Value

Sorting mode, or -1 if the list is not sorted.

Example:

```
//--- example for CList::SortMode()
#include <Arrays\List.mqh>
//---
void OnStart()
{
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- check sort mode
    int sort_mode=list.SortMode();
    //--- use list
    //--- ...
    //--- delete list
    delete list;
}
```

CreateElement

Creates a new element of the list.

```
CObject* CreateElement()
```

Return Value

Pointer to the newly created element - successful, NULL - cannot create an element.

Note

Method `CreateElement()` in the `CList` class always returns `NULL` and does not perform any actions. If necessary, method `CreateElement()` should be implemented in a derived class.

Example:

```
//--- example for CList::CreateElement(int)
#include <Arrays\List.mqh>
//---
void OnStart()
{
    int    size=100;
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- fill list
    for(int i=0;i<size;i++)
    {
        CObject *object=list.CreateElement();
        if(object==NULL)
        {
            printf("Element create error");
            delete list;
            return;
        }
        list.Add(object);
    }
    //--- use list
    //--- . . .
    //--- delete list
    delete list;
}
```

Add

Adds an element to the end of the list.

```
int Add(  
    CObject* element    // element to add  
)
```

Parameters

element

[in] Value of the element to add to the list.

Return Value

Index of the added element - success, -1 - error.

Note

The element is not added to the list, if an invalid pointer (for example, NULL) is passed as a parameter.

Example:

```
///--- example for CList::Add(CObject*)  
#include <Arrays\List.mqh>  
///---  
void OnStart()  
{  
    CList *list=new CList;  
    ///---  
    if(list==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add 100 elements  
    for(int i=0;i<100;i++)  
    {  
        if(list.Add(new CObject)==-1)  
        {  
            printf("Element addition error");  
            delete list;  
            return;  
        }  
    }  
    ///--- use list  
    ///--- . . .  
    ///--- delete list  
    delete list;  
}
```

Insert

Inserts an element to the specified position in the list.

```
int Insert(  
    CObject* element,    // element to insert  
    int      pos         // position  
)
```

Parameters

element

[in] value of the element to insert in the list

pos

[in] position in the list to insert

Return Value

index of inserted element - success, -1 - error.

Note

The element is not added to the list, if an invalid pointer (for example, NULL) is passed as a parameter.

Example:

```
//--- example for CList::Insert(CObject*,int)  
#include <Arrays\List.mqh>  
//---  
void OnStart()  
{  
    CList *list=new CList;  
    //---  
    if(list==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- insert 100 elements  
    for(int i=0;i<100;i++)  
    {  
        if(list.Insert(new CObject,0)==-1)  
        {  
            printf("Element insert error");  
            delete list;  
            return;  
        }  
    }  
    //--- use list  
    //--- . . .
```

```
//--- delete list  
delete list;  
}
```

DetachCurrent

Extracts an element from the current position in the list without its "physical" deletion.

```
CObject* DetachCurrent()
```

Return Value

Pointer to the removed element in case of success, NULL - cannot remove the element.

Note

When removed from the list, the element is not removed in any state of the memory management flag. The pointer to the extracted element should be released after it has been used.

Example:

```
//--- example for CList::DetachCurrent()
#include <Arrays\List.mqh>
//---
void OnStart()
{
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add list elements
    //--- . . .
    CObject *object=list.DetachCurrent();
    if(object==NULL)
    {
        printf("Detach error");
        delete list;
        return;
    }
    //--- use element
    //--- . . .
    //--- delete element
    delete object;
    //--- delete list
    delete list;
}
```

DeleteCurrent

Removes the element from the current position in the list.

```
bool DeleteCurrent()
```

Return Value

true - successful, false - cannot remove the element.

Note

If the memory management is enabled, memory for the removed element is deallocated.

Example:

```
///--- example for CList::DeleteCurrent()
#include <Arrays\List.mqh>
///---
void OnStart()
{
    CList *list=new CList;
    ///---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    ///--- add list elements
    ///--- . . .
    if(!list.DeleteCurrent())
    {
        printf("Delete error");
        delete list;
        return;
    }
    ///--- delete list
    delete list;
}
```

Delete

Removes the element from the given position in the list.

```
bool Delete(  
    int pos    // position  
)
```

Parameters

pos

[in] position of element to be removed from the list.

Return Value

true - successful, false - cannot remove the element.

Note

If the memory management flag is enabled, the memory used for the deleted element is released.

Example:

```
///--- example for CList::Delete(int)  
#include <Arrays\List.mqh>  
///---  
void OnStart()  
{  
    CList *list=new CList;  
    ///---  
    if(list==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add list elements  
    ///--- . . .  
    if(!list.Delete(0))  
    {  
        printf("Delete error");  
        delete list;  
        return;  
    }  
    ///--- delete list  
    delete list;  
}
```

Clear

Removes all elements of the list.

```
void Clear()
```

Note

If the memory management is enabled, the memory of deleted elements is deallocated.

Example:

```
//--- example for CList::Clear()
#include <Arrays\List.mqh>
//---
void OnStart()
{
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add list elements
    //--- . . .
    //--- clear list
    list.Clear();
    //--- delete list
    delete list;
}
```

IndexOf

Gets the index of the specified list element.

```
int IndexOf(  
    CObject* element    // pointer to the element  
)
```

Parameters

element

[in] pointer to the list element.

Return Value

List element index, or -1.

Example:

```
///--- example for CList::IndexOf(CObject*)  
#include <Arrays\List.mqh>  
///---  
void OnStart()  
{  
    CList *list=new CList;  
    ///---  
    if(list==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    CObject *object=new CObject;  
    if(object==NULL)  
    {  
        printf("Element create error");  
        delete list;  
        return;  
    }  
    if(list.Add(object))  
    {  
        int pos=list.IndexOf(object);  
    }  
    ///--- delete list  
    delete list;  
}
```

GetNodeAtIndex

Gets an element from the specified position in the list.

```
CObject* GetNodeAtIndex(  
    int pos      // position  
)
```

Parameters

pos

[in] element position in the list.

Return Value

pointer to the element - success, NULL - cannot receive a pointer.

Example:

```
//--- example for CList::GetNodeAtIndex(int)  
#include <Arrays\List.mqh>  
//---  
void OnStart()  
{  
    CList *list=new CList;  
    //---  
    if(list==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add list elements  
    //--- . . .  
    CObject *object=list.GetNodeAtIndex(10);  
    if(object==NULL)  
    {  
        printf("Get node error");  
        delete list;  
        return;  
    }  
    //--- use element  
    //--- . . .  
    //--- do not delete element  
    //--- delete list  
    delete list;  
}
```

GetFirstNode

Gets the first element of the list.

```
CObject* GetFirstNode()
```

Return Value

Pointer to the first element - success, NULL - cannot get a pointer.

Example:

```
//--- example for CList::GetFirstNode()
#include <Arrays\List.mqh>
//---
void OnStart()
{
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add list elements
    //--- . . .
    CObject *object=list.GetFirstNode();
    if(object==NULL)
    {
        printf("Get node error");
        delete list;
        return;
    }
    //--- use element
    //--- . . .
    //--- do not delete element
    //--- delete list
    delete list;
}
```

GetPrevNode

Gets the previous element of the list.

```
CObject* GetPrevNode()
```

Return Value

Pointer to the previous element - successful, NULL - cannot get a pointer.

Example:

```
//--- example for CList::GetPrevNode()
#include <Arrays\List.mqh>
//---
void OnStart()
{
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add list elements
    //--- . . .
    CObject *object=list.GetPrevNode();
    if(object==NULL)
    {
        printf("Get node error");
        delete list;
        return;
    }
    //--- use element
    //--- . . .
    //--- do not delete element
    //--- delete list
    delete list;
}
```

GetCurrentNode

Gets the current list element.

```
CObject* GetCurrentNode()
```

Return Value

Pointer to the current element - successful, NULL - cannot get a pointer.

Example:

```
//--- example for CList::GetCurrentNode()
#include <Arrays\List.mqh>
//---
void OnStart()
{
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add list elements
    //--- . . .
    CObject *object=list.GetCurrentNode();
    if(object==NULL)
    {
        printf("Get node error");
        delete list;
        return;
    }
    //--- use element
    //--- . . .
    //--- do not delete element
    //--- delete list
    delete list;
}
```

GetNextNode

Gets the next element in the list.

```
CObject* GetNextNode()
```

Return Value

Pointer to the next element - successful, NULL - cannot get a pointer.

Example:

```
//--- example for CList::GetNextNode()
#include <Arrays\List.mqh>
//---
void OnStart()
{
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add list elements
    //--- . . .
    CObject *object=list.GetNextNode();
    if(object==NULL)
    {
        printf("Get node error");
        delete list;
        return;
    }
    //--- use element
    //--- . . .
    //--- do not delete element
    //--- delete list
    delete list;
}
```

GetLastNode

Gets the last element of the list.

```
CObject* GetLastNode()
```

Return Value

Pointer to the last element - success, NULL - cannot get a pointer.

Example:

```
//--- example for CList::GetLastNode()
#include <Arrays\List.mqh>
//---
void OnStart()
{
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- add list elements
    //--- . . .
    CObject *object=list.GetLastNode();
    if(object==NULL)
    {
        printf("Get node error");
        delete list;
        return;
    }
    //--- use element
    //--- . . .
    //--- do not delete element
    //--- delete list
    delete list;
}
```

Sort

Sorts a list.

```
void Sort(  
    int mode    // sorting mode  
)
```

Parameters

mode

[in] Sorting mode.

Return Value

No.

Note

The list is always sorted in ascending order.

Example:

```
//--- example for CList::Sort(int)  
#include <Arrays\List.mqh>  
//---  
void OnStart()  
{  
    CList *list=new CList;  
    //---  
    if(list==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- sorting by mode 0  
    list.Sort(0);  
    //--- use list  
    //--- ...  
    //--- delete list  
    delete list;  
}
```

MoveToIndex

Moves the current element in the list to the specified position.

```
bool MoveToIndex(  
    int pos    // position  
)
```

Parameters

pos

[in] position in the list to move.

Return Value

true - successful, false - cannot move the element.

Example:

```
//--- example for CList::MoveToIndex(int)  
#include <Arrays\List.mqh>  
//---  
void OnStart()  
{  
    CList *list=new CList;  
    //---  
    if(list==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- move current node to begin  
    list.MoveToIndex(0);  
    //--- use list  
    //--- . . .  
    //--- delete list  
    delete list;  
}
```

Exchange

Swaps two elements in the list.

```
bool Exchange(  
    CObject* node1,    // list element  
    CObject* node2     // list element  
)
```

Parameters

node1

[in] list element

node2

[in] list element

Return Value

true - successful, false - cannot swap the elements.

Example:

```
//--- example for CList::Exchange(CObject*,CObject*)  
#include <Arrays\List.mqh>  
//---  
void OnStart()  
{  
    CList *list=new CList;  
    //---  
    if(list==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- exchange  
    list.Exchange(list.GetFirstNode(),list.GetLastNode());  
    //--- use list  
    //--- . . .  
    //--- delete list  
    delete list;  
}
```

CompareList

Compares the list with another one.

```
bool CompareList(  
    CList* list      // pointer to the source  
)
```

Parameters

list

[in] a pointer to an instance of the CList class used as a source of elements for comparison.

Return Value

true - the lists are equal, false - the lists are not equal.

Example:

```
//--- example for CList::CompareList(const CList*)  
#include <Arrays\List.mqh>  
//---  
void OnStart()  
{  
    CList *list=new CList;  
    //---  
    if(list==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- create source list  
    CList *src=new CList;  
    if(src==NULL)  
    {  
        printf("Object create error");  
        delete list;  
        return;  
    }  
    //--- fill source list  
    //--- . . .  
    //--- compare with another list  
    bool result=list.CompareList(src);  
    //--- delete lists  
    delete src;  
    delete list;  
}
```

Search

Searches for an element equal to the sample in the sorted list.

```
CObject* Search(  
    CObject* element    // sample  
)
```

Parameters

element

[in] element sample to search for in the list.

Return Value

Pointer to the found element - successful, NULL - the element is not found.

Example:

```
//--- example for CList::Search(CObject*)  
#include <Arrays\List.mqh>  
//---  
void OnStart()  
{  
    CList *list=new CList;  
    //---  
    if(list==NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- add lists elements  
    //--- . . .  
    //--- sort list  
    list.Sort(0);  
    //--- create sample  
    CObject *sample=new CObject;  
    if(sample==NULL)  
    {  
        printf("Sample create error");  
        delete list;  
        return;  
    }  
    //--- set sample attributes  
    //--- . . .  
    //--- search element  
    if(list.Search(sample)!=NULL) printf("Element found");  
    else                          printf("Element not found");  
    //--- delete list  
    delete list;  
}
```

Save

Saves list data in the file.

```
virtual bool Save(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen () function.

Return Value

true - successfully completed, false - error.

Example:

```
///--- example for CList::Save(int)  
#include <Arrays\List.mqh>  
///---  
void OnStart()  
{  
    int file_handle;  
    CList *list=new CList;  
    ///---  
    if(list!=NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    ///--- add lists elements  
    ///--- . . .  
    ///--- open file  
    file_handle=FileOpen("MyFile.bin",FILE_WRITE|FILE_BIN|FILE_ANSI);  
    if(file_handle>=0)  
    {  
        if(!list.Save(file_handle))  
        {  
            ///--- file save error  
            printf("File save: Error %d!",GetLastError());  
            delete list;  
            FileClose(file_handle);  
            ///---  
            return;  
        }  
        FileClose(file_handle);  
    }  
    ///--- delete list  
    delete list;
```

```
}
```

Load

Loads list data from the file.

```
virtual bool Load(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] Handle of the binary file previously opened using the FileOpen () function.

Return Value

true - successfully completed, false - error.

Note

When reading list elements from the file, the [CList::CreateElement\(int\)](#) method is called to create each element.

Example:

```
//--- example for CLoad::Load(int)  
#include <Arrays\List.mqh>  
//---  
void OnStart()  
{  
    int file_handle;  
    CList *list=new CList;  
    //---  
    if(list!=NULL)  
    {  
        printf("Object create error");  
        return;  
    }  
    //--- open file  
    file_handle=FileOpen("MyFile.bin",FILE_READ|FILE_BIN|FILE_ANSI);  
    if(file_handle>=0)  
    {  
        if(!list.Load(file_handle))  
        {  
            //--- file load error  
            printf("File load: Error %d!",GetLastError());  
            delete list;  
            FileClose(file_handle);  
            //---  
            return;  
        }  
        FileClose(file_handle);  
    }  
}
```

```
//--- use list elements  
//--- . . .  
//--- delete list  
delete list;  
}
```

Type

Gets the list type identifier.

```
virtual int Type()
```

Return Value

List type identifier (for CList - 7779).

Example:

```
//--- example for CList::Type()
#include <Arrays\List.mqh>
//---
void OnStart()
{
    CList *list=new CList;
    //---
    if(list==NULL)
    {
        printf("Object create error");
        return;
    }
    //--- get list type
    int type=list.Type();
    //--- delete list
    delete list;
}
```

CTreeNode

CTreeNode is a class of the CTree binary tree node.

Description

CTreeNode provides the ability to work with nodes of the [CTree](#) binary tree. Options of navigation through the tree are implemented in the class. Besides, methods of working with the file are implemented.

Declaration

```
class CTreeNode : public CObject
```

Title

```
#include <Arrays\TreeNode.mqh>
```

Inheritance hierarchy

[CObject](#)

CTreeNode

Direct descendants

[CTree](#)

Class Methods by Groups

Attributes	
Owner	Gets/sets the pointer of the owner node
Left	Gets/sets the pointer of the left node
Right	Gets/sets the pointer of the right node
Balance	Gets the node balance
BalanceL	Gets the balance of the left sub-branch of the node
BalanceR	Gets the balance of the right sub-branch of the node
Creation of a new element	
CreateSample	Creates a new node instance
Comparison	
RefreshBalance	Recalculates the node balance
Search	
GetNext	Gets the pointer of the next node

Input/Output	
SaveNode	Saves the node data to a file
LoadNode	Downloads the node data from a file
virtual Type	Gets the identifier of the node type

Methods inherited from class CObject

Prev, Prev, Next, Next, [Save](#), [Load](#), [Compare](#)

Trees of CTreeNode class descendants have practical application.

A descendant of CTreeNode class should have predefined methods: [CreateSample](#) creates a new instance of the descendant class of CTreeNode, [Compare](#) compares values of key fields of the descendant class of CTreeNode, [Type](#) (if it is necessary to identify a node), [SaveNode](#) and [LoadNode](#) (if it is necessary to work with a file).

Let's consider an example of a CTree descendant class.

//--- reading custom variable of datetime type
    m_datetime=FileReadLong(file_handle);
//---
    return(true);
}
```

Owner

Gets the pointer of the owner node.

```
CTreeNode* Owner()
```

Return Value

Pointer of the owner node.

Owner

Sets the pointer of the owner node.

```
void Owner(  
    CTreeNode* node    // node  
)
```

Parameters

node

[in] New value of the pointer of the owner node.

Return Value

None.

Left

Gets the pointer of the left node.

```
CTreeNode* Left()
```

Return Value

Pointer of the left node.

Left

Sets the pointer of the left node.

```
void Left(  
    CTreeNode* node    // node  
)
```

Parameters

node

[in] New value of the pointer of the left node.

Return Value

None.

Right

Gets the pointer of the right node.

```
CTreeNode* Right()
```

Return Value

The pointer of the right node.

Right

Sets the pointer of the right node.

```
void Right(  
    CTreeNode* node    // node  
)
```

Parameters

node

[in] New value of the pointer of the right node.

Return Value

None.

Balance

Gets the node balance.

```
int Balance() const
```

Return Value

Node balance.

BalanceL

Gets the balance of the left sub-branch of the node.

```
int BalanceL() const
```

Return Value

Balance of the left sub-branch of the node.

BalanceR

Gets the balance of the right sub-branch of the node.

```
int BalanceR() const
```

Return Value

Balance of the right sub-branch of the node.

CreateSample

Creates a new node sample.

```
virtual CTreeNode* CreateSample()
```

Return Value

Pointer to the new node sample or NULL.

RefreshBalance

Recalculates the node balance.

```
int RefreshBalance()
```

Return Value

Node balance.

GetNext

Gets the pointer of the next node.

```
CTreeNode* GetNext (  
    CTreeNode* node    // node  
)
```

Parameters

node

[in] Node of the search start.

Return Value

Pointer of the next node.

SaveNode

Writes node data to a file.

```
bool SaveNode(  
    int file_handle    // handle  
)
```

Parameters

file_handle

[in] Handle of a binary file that was earlier opened for writing.

Return Value

true - success, otherwise false.

LoadNode

Reads node data from a file.

```
bool LoadNode(  
    int      file_handle,    // handle  
    CTreeNode* main          // node  
)
```

Parameters

file_handle

[in] Handle of a binary file that was earlier opened for reading.

main

[in] Node for data.

Return Value

true - success, otherwise false.

Type

Gets the identifier of the node type.

```
virtual int Type() const
```

Return Value

Identifier of the node type.

CTree

CTree is a class of the binary tree of the instances of CTreeNode class and its descendants.

Description

CTree class provides the possibility to work with the binary tree of [CTreeNode](#) class instances and its descendants. Options of adding/inserting/deleting of tree elements and search in the tree are implemented in the class. Besides that, methods of working with a file are implemented.

Note that mechanism of dynamic memory management is not implemented in class CTree (unlike classes [CList](#) and [CArrayObj](#)). All tree nodes are deleted with memory deallocation.

Declaration

```
class CTree : public CTreeNode
```

Title

```
#include <Arrays\Tree.mqh>
```

Inheritance hierarchy

[CObject](#)

[CTreeNode](#)

CTree

Class Methods by Groups

Attributes	
Root	Gets the root node of the tree
Creation of a new element	
CreateElement	Creates a new instance of the node
Filling	
Insert	Adds a node to a tree
Deletion	
Detach	Detaches a specified node from a tree
Delete	Deletes a specified node from a tree
Clear	Deletes all nodes of a tree
Search	
Find	Searches for a node in a tree by sample
Input/output	
virtual Save	Saves all the tree data to a file

virtual Load	Downloads tree data from a file
virtual Type	Gets identifier of the tree type

Methods inherited from class CObject

Prev, Prev, Next, Next, [Compare](#)

Methods inherited from class CTreeNode

Parent, Parent, [Left](#), [Left](#), [Right](#), [Right](#), [Balance](#), [BalanceL](#), [BalanceR](#), [RefreshBalance](#), [GetNext](#), [SaveNode](#), [LoadNode](#)

Trees of CTreeNode class descendants - descendants of class CTree - have practical application.

Descendant of CTree class should have a predefined method [CreateElement](#) that creates a new instance of the [CTreeNode](#) descendant class.

Let's consider an example of the CTree descendant class.

    }
    node.SetString(str_array[mode%10]);
    node.SetDateTime(10000*mode);
}

```

Root

Gets the root node of the tree.

```
CTreeNode* Root() const
```

Return Value

Pointer of the root node of the tree.

CreateElement

Creates a new instance of the node.

```
virtual CTreeNode* CreateElement()
```

Return Value

Pointer of the new instance of the node or NULL.

Insert

Adds a node to a tree.

```
CTreeNode* Insert(  
    CTreeNode* new_node    // node  
)
```

Parameters

new_node

[in] Pointer of a node to insert to a tree.

Return Value

Pointer of the owner node or NULL.

Detach

Detaches a specified node from a tree.

```
bool Detach(  
    CTreeNode* node    // node  
)
```

Parameters

node

[in] Node pointer to detach.

Return Value

true - success, otherwise false.

Note

After detachment, the node pointer is not released. The tree is balanced.

Delete

Deletes a specified node from a tree.

```
bool Delete(  
    CTreeNode* node    // node  
)
```

Parameters

node

[in] Node pointer to delete.

Return Value

true - success, otherwise false.

Note

After deletion, a node pointer is released. The tree is balanced.

Clear

Deletes all nodes of a tree.

```
void Clear()
```

Return Value

None.

Note

After deletion, node pointers are released.

Find

Searches for a node in a tree by sample.

```
CTreeNode* Find(  
    CTreeNode* node    // node  
)
```

Parameters

node

[in] Node that contains data used as a search sample.

Return Value

Pointer of the found node or NULL.

Save

Writes tree data to a file.

```
virtual bool Save(  
    int file_handle    // handle  
)
```

Parameters

file_handle

[in] Handle of a binary file that was earlier opened for writing.

Return Value

true - success, otherwise false.

Load

Reads tree data from a file.

```
virtual bool Load(  
    int file_handle    // handle  
)
```

Parameters

file_handle

[in] Handle of a binary file that was earlier opened for reading.

Return Value

true - success, otherwise false.

Type

Gets identifier of the tree type.

```
virtual int Type() const
```

Return Value

Identifier of the tree type.

File Operations

This section contains the technical details of the file operations classes and descriptions of the corresponding components of the MQL5 standard library.

The file operations classes will save time in developing applications using file input/output operations.

The MQL5 Standard Library (in terms of file operations) is located in the working directory of the terminal in the Include\Files folder.

Class	Description
<u>CFile</u>	Base file operations class
<u>CFileBin</u>	Binary file operations class
<u>CFileTxt</u>	Text file operations class

CFile

CFile is a base class for CFileBin and CFileTxt classes.

Description

CFile class provides the simplified access to MQL5 API file and folder functions for all of its descendants.

Declaration

```
class CFile: public CObject
```

Title

```
#include <Files\File.mqh>
```

Inheritance hierarchy

CObject

CFile

Direct descendants

CFileBin, CFilePipe, CFileTxt

Class Methods by Groups

Attributes	
<u>Handle</u>	Gets file handle
<u>Filename</u>	Gets file name
<u>Flags</u>	Gets file flags
<u>SetUnicode</u>	Sets/clears the FILE_UNICODE flag
<u>SetCommon</u>	Sets/clears the FILE_COMMON flag
General methods for files	
<u>Open</u>	Opens file
<u>Close</u>	Closes file
<u>Delete</u>	Deletes file
<u>IsExist</u>	Checks file for existence
<u>Copy</u>	Copies file
<u>Move</u>	Renames/moves file
<u>Size</u>	Gets file size
<u>Tell</u>	Gets current file position

Seek	Sets current file position
Flush	Flushes data on disk
IsEnding	Checks file for end
IsLineEnding	Checks line for end
General methods for folders	
FolderCreate	Creates folder
FolderDelete	Deletes folder
FolderClean	Clears folder
Files and folders search methods	
FileFindFirst	Begins file search
FileFindNext	Continues file search
FileFindClose	Closes search handle

Methods inherited from class CObject

Prev, Prev, Next, Next, [Save](#), [Load](#), [Type](#), [Compare](#)

Handle

Gets file handle of the opened file.

```
int Handle()
```

Return Value

Handle of the opened file assigned to the class instance. If there is no file assigned, it returns -1.

FileName

Gets file name of the opened file.

```
string FileName()
```

Return Value

File name of the opened fil, assigned to the class instance. If there is no file assigned, it returns "".

Flags

Gets flags of the opened file.

```
int  Flags ()
```

Return Value

Flags of the opened file assigned to the class instance.

SetUnicode

Sets/clears the FILE_UNICODE flag.

```
void SetUnicode(  
    bool unicode    // flag value  
)
```

Parameters

unicode

[in] New value for FILE_UNICODE flag.

Note

The result of string operations is dependent on the FILE_UNICODE flag. If it is false, the ANSI codes are used (one byte symbols). If it set, the UNICODE codes are used (two byte symbols). If the file is already opened, the flag cannot be changed.

SetCommon

Sets/clears the FILE_COMMON flag.

```
void SetCommon(  
    bool common    // flag value  
)
```

Parameters

common

[in] New value for FILE_COMMON flag.

Note

The FILE_COMMON flag determines the current working folder. If it is false, the local terminal folder is used as the current working folder. If it is true, the common data folder is used as the current working folder. If the file is already opened, the flag cannot be changed.

Open

Opens the specified file and, if it successful, assigns it to the class instance.

```
int Open(  
    const string file_name,      // file name  
    int flags,                  // flags  
    short delimiter=9           // separator  
)
```

Parameters

file_name

[in] File name to open.

flags

[in] File open flags.

delimiter=9

[in] CSV file separator.

Return Value

Handle of the opened file.

Note

The working folder is dependent on flag that was previously set/reset using the SetCommon() method.

Close

Closes file assigned to the class instance.

```
void Close()
```

Delete

Deletes the file assigned to the file instance.

```
void Delete()
```

Delete

Deletes the specified file.

```
void Delete(  
    const string file_name    // file name  
)
```

Parameters

file_name

[in] File name of the file to delete.

Note

The working folder is dependent on the flag that was previously set/reset using the SetCommon() method.

IsExist

Checks file for existence

```
bool IsExist(  
    const string file_name    // file name  
)
```

Parameters

file_name

[in] Name of the file to check.

Return Value

true - file exists.

Copy

Copies a file.

```
bool Copy(  
    const string src_name,      // file name  
    int src_flag,              // flag  
    const string dst_name,      // file name  
    int dst_flags              // flags  
)
```

Parameters

src_name

[in] Name of a source file.

src_flag

[in] Flags of a source file (only FILE_COMMON is used).

dst_name

[in] File name of the destination file.

dst_flags

[in] Flags of the destination file (only FILE_REWRITE and FILE_COMMON are used).

Return Value

true - successful, false - cannot copy the file.

Move

Renames/moves file.

```
bool Move(  
    const string src_name,      // file name  
    int src_flag,              // flag  
    const string dst_name,      // file name  
    int dst_flags              // flags  
)
```

Parameters

src_name

[in] Source file name.

src_flag

[in] Source file flags (only FILE_COMMON is used).

dst_name

[in] File name of the destination file.

dst_flags

[in] Flags of the destination file (only FILE_REWRITE and FILE_COMMON are used).

Return Value

true - successful, false - failed to move/rename the file.

Size

Gets file size in bytes.

```
ulong Size()
```

Return Value

file size in bytes. If there is no file assigned, it returns ULONG_MAX.

Tell

Gets the current file pointer's position.

```
ulong Tell()
```

Return Value

the current file position. If there no file assigned, it returns ULONG_MAX.

Seek

Sets file pointer's position.

```
void Seek(  
    long          offset,      // offset  
    ENUM_FILE_POSITION origin  // origin  
)
```

Parameters

offset

[in] File offset in bytes (can be negative).

origin

[in] Origin of the offset.

Return Value

true - successful, false - cannot change the file pointer.

Flush

Flushes all of the file input/output buffer data on disk.

```
void Flush()
```

IsEnding

Checks file for end during the file read operations.

```
bool IsEnding()
```

Return Value

true - end of file has been achieved during read or seek operation.

IsLineEnding

Checks a text file for end during the file read operations.

```
bool IsLineEnding()
```

Return Value

true - end of line has been achieved during a txt or csv file read operation (CR-LF chars).

FolderCreate

Creates new folder.

```
bool FolderCreate(  
    const string folder_name    // folder name  
)
```

Parameters

folder_name

[in] Name of the folder to create. It contains path to the folder relative to the folder defined by FILE_COMMON flag.

Return Value

true - successful, false - cannot create the folder.

Note

The working folder is dependent on the flag that was previously set/reset using the SetCommon() method.

FolderDelete

Deletes specified folder.

```
bool FolderDelete(  
    const string folder_name    // folder name  
)
```

Parameters

folder_name

[in] Name of the folder to delete. It contains path to the folder relative to the folder defined by FILE_COMMON flag.

Return Value

true - successful, false - cannot delete the folder.

Note

The working folder is dependent on the flag that was previously set/reset using the SetCommon() method.

FolderClean

Cleans specified folder.

```
bool FolderClean(  
    const string folder_name    // folder name  
)
```

Parameters

folder_name

[in] Name of the folder to clean. It contains path to the folder relative to the folder defined by FILE_COMMON flag.

Return Value

true - successful, and false - cannot change the folder.

Note

The working folder is dependent on the flag previously set/reset by SetCommon() method.

FileFindFirst

Begins file search using the specified filter.

```
int FileFindFirst(  
    const string filter,          // search filter  
    string&      file_name       // reference  
)
```

Parameters

filter

[in] Search filter.

file_name

[out] The reference to the string the name of the first found file is placed into in case of success.

Return Value

The handle that can be used for further file search using FileFindNext, or INVALID_HANDLE if there are no files corresponding to the filter.

Note

The working folder is dependent on the flag previously set/reset by SetCommon() method.

FileFindNext

Continues file search started by the FileFindFirst() method.

```
bool FileFindNext(  
    int      search_handle,    // search handle  
    string&  file_name        // reference  
)
```

Parameters

search_handle

[in] Search handle returned by FileFindFirst() method.

file_name

[in] The reference to the string the name of the found file is placed into if successful.

Return Value

true - successful, false - there are no files corresponding to the filter.

FileFindClose

Closes search handle.

```
void FileFindClose(  
    int search_handle    // search handle  
)
```

Parameters

search_handle

[in] Search handle returned by FileFindFirst() method.

CFileBin

CFileBin is a class for simplified access to binary files.

Description

CFileBin class provides access to binary files.

Declaration

```
class CFileBin: public CFile
```

Title

```
#include <Files\FileBin.mqh>
```

Inheritance hierarchy

[CObject](#)

[CFile](#)

CFileBin

Class Methods by Groups

Open methods	
Open	Opens a binary file
Write methods	
WriteChar	Writes char or uchar type variable
WriteShort	Writes short or ushort type variable
WriteInteger	Writes int or uint type variable
WriteLong	Writes long or ulong type variable
WriteFloat	Writes float type variable
WriteDouble	Writes double type variable
WriteString	Writes string type variable
WriteCharArray	Writes an array of char or uchar type variables
WriteShortArray	Writes an array of short or ushort type variables
WriteIntegerArray	Writes an array of int or uint type variables
WriteLongArray	Writes an array of long or ulong type variables
WriteFloatArray	Writes an array of float variables
WriteDoubleArray	Writes an array of double type variables

WriteObject	Writes data of the CObject class inheritor instance
Read methods	
ReadChar	Reads char or uchar type variable
ReadShort	Reads short or ushort type variable
ReadInteger	Reads int or uint type variable
ReadLong	Reads long or ulong type variable
ReadFloat	Reads float type variable
ReadDouble	Reads double type variable
ReadString	Reads string type variable
ReadCharArray	Reads an array of char or uchar type variables
ReadShortArray	Reads an array of short or ushort type variables
ReadIntegerArray	Reads an array of int or uint type variables
ReadLongArray	Reads an array of long or ulong type variables
ReadFloatArray	Reads an array of float type variables
ReadDoubleArray	Reads an array of double type variables
ReadObject	Reads data of the CObject class inheritor instance

Open

Opens the specified binary file and, if successful, assigns it to the class instance.

```
int Open(  
    const string file_name,    // file name  
    int flags                  // flags  
)
```

Parameters

file_name

[in] File name of the file to open.

flags

[in] File open flags (the FILE_BIN flag is set forcibly).

Return Value

Handle of the opened file.

WriteChar

Writes char or uchar type variable to file.

```
uint WriteChar(  
    char value    // value  
)
```

Parameters

value

[in] Variable to write.

Return Value

Number of bytes written.

WriteShort

Writes short or ushort type variable to file.

```
uint WriteShort(  
    short value    // value  
)
```

Parameters

value

[in] Variable to write.

Return Value

Number of bytes written.

WriteInteger

Writes int or uint type variable to file.

```
uint WriteInteger(  
    int value    // value  
)
```

Parameters

value

[in] Variable to write.

Return Value

Number of bytes written.

WriteLong

Writes long or ulong type variable to file.

```
uint WriteLong(  
    long value    // value  
)
```

Parameters

value

[in] Variable to write.

Return Value

Number of bytes written.

WriteFloat

Writes float type variable to file.

```
uint WriteFloat(  
    float value    // value  
)
```

Parameters

value

[in] Variable to write.

Return Value

Number of bytes written.

WriteDouble

Writes double type variable to file.

```
uint WriteDouble(  
    double value    // value  
)
```

Parameters

value

[in] Variable to write.

Return Value

Number of bytes written.

WriteString

Writes string type variable to file.

```
uint WriteString(  
    const string value    // value  
)
```

Parameters

value

[in] String to write.

Return Value

Number of bytes written.

WriteString

Writes string type variable to file.

```
uint WriteString(  
    const string value,    // value  
    int size              // size  
)
```

Parameters

value

[in] String to write.

size

[in] Number of bytes to write.

Return Value

Number of bytes written.

WriteCharArray

Writes an array of char or uchar type variables to file.

```
uint WriteCharArray(  
    char& array[],           // array  
    int start_item=0,        // start element  
    int items_count=-1       // number of elements  
)
```

Parameters

array[]

[in] Array to write.

start_item=0

[in] Start element to write from.

items_count=-1

[in] Number of elements to write (-1 - whole array).

Return Value

Number of bytes written.

WriteShortArray

Writes an array of short or ushort type variables to file.

```
uint WriteShortArray(  
    short& array[],           // array  
    int start_item=0,         // start element  
    int items_count=-1        // number of elements  
)
```

Parameters

array[]

[in] Array to write.

start_item=0

[in] Start element to write from.

items_count=-1

[in] Number of elements to write (-1 - whole array).

Return Value

Number of bytes written.

WriteIntegerArray

Writes an array of int or uint type variables to file.

```
uint WriteIntegerArray(  
    int& array[],           // array  
    int start_item=0,       // start element  
    int items_count=-1      // number of elements  
)
```

Parameters

array[]

[in] Array to write.

start_item=0

[in] Start element to write from.

items_count=-1

[in] Number of elements to write (-1 - whole array).

Return Value

Number of bytes written.

WriteLongArray

Writes an array of long or ulong type variables to file.

```
uint WriteLongArray(  
    long& array[],           // array  
    int start_item=0,        // start element  
    int items_count=-1       // number of elements  
)
```

Parameters

array[]

[in] Array to write.

start_item=0

[in] Start element to write from.

items_count=-1

[in] Number of elements to write (-1 - whole array).

Return Value

Number of bytes written.

WriteFloatArray

Writes an array of float type variables to file.

```
uint WriteFloatArray(  
    float& array[],           // array  
    int    start_item=0,      // start element  
    int    items_count=-1     // number of elements  
)
```

Parameters

array[]

[in] Array to write.

start_item=0

[in] Start element to write from.

items_count=-1

[in] Number of elements to write (-1 - whole array).

Return Value

Number of bytes written.

WriteDoubleArray

Writes an array of double type variables to file.

```
uint WriteDoubleArray(  
    double& array[],           // array to write  
    int start_item=0,         // start element  
    int items_count=-1        // number of elements  
)
```

Parameters

array[]

[in] Array to write.

start_item=0

[in] Start element to write from.

items_count=-1

[in] Number of elements to write (-1 - whole array).

Return Value

Number of bytes written.

WriteObject

Writes data of the CObject class inheritor instance to file.

```
bool WriteObject(  
    CObject* object    // reference to the object  
)
```

Parameters

object

[in] Reference to the CObject class inheritor instance to write.

Return Value

true - successful, false - cannot write the data.

ReadChar

Reads char or uchar type variable from file.

```
bool ReadChar(  
    char& value    // flag value  
)
```

Parameters

value

[in] Reference to the variable for placing read data.

Return Value

true - successful, false - cannot read the data.

ReadShort

Reads short or ushort type variable from file.

```
bool ReadShort(  
    short& value  
)
```

Parameters

value

[in] Reference to the variable for placing read data.

Return Value

true - successful, false - cannot read the data.

ReadInteger

Reads int or uint type variable from file.

```
bool ReadInteger(  
    int& value    // variable  
)
```

Parameters

value

[in] Reference to the variable for placing read data.

Return Value

true - successful, false - cannot read the data.

ReadLong

Reads long or ulong type variable from file.

```
bool ReadLong(  
    long& value  
)
```

Parameters

value

[in] Reference to the variable for placing read data.

Return Value

true - successful, false - cannot read the data.

ReadFloat

Reads float type variable from file.

```
bool ReadFloat(  
    float& value    // variable  
)
```

Parameters

value

[in] Reference to the variable for placing read data.

Return Value

true - successful, false - cannot read the data.

ReadDouble

Reads double type variable from file.

```
bool ReadDouble(  
    double& value  
)
```

Parameters

value

[in] Reference to the variable for placing read data.

Return Value

true - successful, false - cannot read the data.

ReadString

Reads string type variable from file.

```
bool ReadString(  
    string& value    // string  
)
```

Parameters

value

[in] Reference to the variable for placing read data.

Return Value

true - successful, false - cannot read the data.

ReadString

Reads string type variable from file.

```
bool ReadString(  
    string& value  
)
```

Parameters

value

[in] Reference to the variable for placing read data.

Return Value

true - successful, false - cannot read the data.

ReadCharArray

Reads an array of char or uchar type variables from file.

```
bool ReadCharArray(  
    char& array[],           // array  
    int start_item=0,        // start element  
    int items_count=-1       // number of elements  
)
```

Parameters

array[]

[in] Reference to the variable for placing read data.

start_item=0

[in] Start element to read from.

items_count=-1

[in] Number of elements to read (-1 - read to the end of file).

Return Value

true - successful, false - cannot read the data.

ReadShortArray

Reads an array of short or ushort type variables from file.

```
bool ReadShortArray(  
    short& array[],           // array  
    int start_item=0,        // start element  
    int items_count=-1       // number of elements  
)
```

Parameters

array[]

[in] Reference to the variable for placing read data.

start_item=0

[in] Start element to read from.

items_count=-1

[in] Number of elements to read (-1 - read to the end of file).

Return Value

true - successful, false - cannot read the data.

ReadIntegerArray

Reads an array of int or uint type variables from file.

```
bool ReadIntegerArray(  
    int& array[],           // array  
    int start_item=0,      // start element  
    int items_count=-1     // number of elements  
)
```

Parameters

array[]

[in] Reference to the target array of type int or uint.

start_item=0

[in] Start element to read from.

items_count=-1

[in] Number of elements to read (-1 - read to the end of file).

Return Value

true - successful, false - cannot read the data.

ReadLongArray

Reads an array of long or ulong type variables from file.

```
bool ReadLongArray(  
    long& array[],           // array  
    int start_item=0,       // start element  
    int items_count=-1      // number of elements  
)
```

Parameters

array[]

[in] Reference to the variable for placing read data.

start_item=0

[in] Start element to read from.

items_count=-1

[in] Number of elements to read (-1 - read to the end of file).

Return Value

true - successful, false - cannot read the data.

ReadFloatArray

Reads an array of float type variables from file.

```
bool ReadFloatArray(  
    float& array[],           // array  
    int start_item=0,        // start element  
    int items_count=-1       // number of elements  
)
```

Parameters

array[]

[in] Reference to the variable for placing read data.

start_item=0

[in] Start element to read from.

items_count=-1

[in] Number of elements to read (-1 - read to the end of file).

Return Value

true - successful, false - cannot read the data.

ReadDoubleArray

Reads an array of double type variables from file.

```
bool ReadDoubleArray(  
    double& array[],           // array  
    int start_item=0,         // start element  
    int items_count=-1        // number of elements  
)
```

Parameters

array[]

[in] Reference to the variable for placing read data.

start_item=0

[in] Start element to read from.

items_count=-1

[in] Number of elements to read (-1 - read to the end of file).

Return Value

true - successful, false - cannot read the data.

ReadObject

Reads data of the CObject class inheritor instance from file.

```
bool ReadObject(  
    CObject* object    // pointer  
)
```

Parameters

object

[in] Pointer to the CObject class inheritor instance to read.

Return Value

true - successful, false - cannot read the data.

CFileTxt

CFileTxt is a class for simplified access to text files.

Description

CFileTxt class provides access to text files.

Declaration

```
class CFileTxt: public CFile
```

Title

```
#include <Files\FileTxt.mqh>
```

Inheritance hierarchy

[CObject](#)

[CFile](#)

CFileTxt

Class Methods by Groups

Open methods	
Open	Opens a text file
Write methods	
WriteString	Writes string type variable
Read methods	
ReadString	Reads string type variable

Methods inherited from class CObject

Prev, Prev, Next, Next, [Save](#), [Load](#), [Type](#), [Compare](#)

Methods inherited from class CFile

[Handle](#), [FileName](#), [Flags](#), [SetUnicode](#), [SetCommon](#), [Open](#), [Close](#), [Delete](#), [Size](#), [Tell](#), [Seek](#), [Flush](#), [IsEnding](#), [IsLineEnding](#), [Delete](#), [IsExist](#), [Copy](#), [Move](#), [FolderCreate](#), [FolderDelete](#), [FolderClean](#), [FileFindFirst](#), [FileFindNext](#), [FileFindClose](#)

Open

Opens the specified text file and, if successful, assigns it to the class instance.

```
int Open(  
    const string file_name,    // file name  
    int flags                 // flags  
)
```

Parameters

file_name

[in] File name to open.

flags

[in] File open flags (FILE_TXT flag is forcibly set).

Return Value

Opened file handle.

WriteString

Writes string type variable to file.

```
uint WriteString(  
    const string value    // string  
)
```

Parameters

value

[in] String to write.

Return Value

Number of bytes written.

ReadString

Reads string type variable from file.

```
string ReadString()
```

Return Value

String which has been read.

String operations

This section contains the technical details of the string operations classes and descriptions of the corresponding components of the MQL5 standard library.

The use of string operations classes will save time in developing applications processing textual data.

The MQL5 standard library (in terms of string operations) is located in the working directory of the terminal in the Include\Strings folder.

Class	Description
<u>CString</u>	Class for string operations

CString

CString is a class for simplified access to the variables of string type.

Description

CString class provides simplified access to MQL5 API functions working with string variables.

Declaration

```
class CString: public CObject
```

Title

```
#include <Strings\String.mqh>
```

Inheritance hierarchy

[CObject](#)

CString

Class Methods by Groups

Data access methods	
Str	Gets a string
Len	Gets length of a string
Copy	Copies a string copy
Fill methods	
Fill	Fills a string
Assign	Assigns a string
Append	Appends a string
Insert	Inserts a string
Compare methods	
Compare	Compares strings
CompareNoCase	Performs a case insensitive string comparison
Substring methods	
Left	Gets a substring from the left
Right	Gets a substring from the right
Mid	Gets a substring from the middle
Trim/delete methods	

Trim	Trims a string from the left and from the right
TrimLeft	Trims a string from the left
TrimRight	Trims a string from the right
Clear	Clears a string
Convert methods	
ToUpper	Converts a string to uppercase.
ToLower	Converts a string to lowercase.
Reverse	Reverses a string
Search methods	
Find	Searches a substring left to right
FindRev	Searches a substring right to left
Remove	Deletes a substring
Replace	Replaces a substring

Methods inherited from class CObject

Prev, [Prev](#), [Next](#), [Next](#), [Save](#), [Load](#), [Type](#)

Str

Gets a string.

```
string Str() const;
```

Return Value

Copy of a string.

Len

Gets length of a string.

```
uint Len() const;
```

Return Value

Length of a string.

Copy

Copies a string by reference.

```
void Copy(  
    string& copy      // reference  
    ) const;
```

Parameters

copy

[in] Reference to a data string.

Copy

Copies a string to the CString class instance.

```
void Copy(  
    CString* copy      // pointer  
    ) const;
```

Parameters

copy

[in] Pointer to CString class instance for data.

Fill

Fills a string with specified char.

```
bool Fill(  
    short character    // character  
)
```

Parameters

character

[in] Character for filling a string.

Return Value

true - successful, false - cannot fill a string.

Assign

Assigns a string.

```
void Assign(  
    const string str    // string  
)
```

Parameters

str

[in] String to assign.

Assign

Assigns a string from the CString class instance.

```
void Assign(  
    CString* str        // pointer  
)
```

Parameters

str

[in] Pointer to the CString class instance to assign.

Append

Appends a string.

```
void Append(  
    const string str      // string  
)
```

Parameters

str

[in] String to append.

Append

Appends a string from the CString class instance.

```
void Append(  
    CString* string      // pointer  
)
```

Parameters

string

[in] Pointer to the CString class instance to append.

Insert

Inserts a string to the specified position.

```
uint Insert(  
    uint      pos,      // position  
    const string str     // string  
)
```

Parameters

pos

[in] Insert position.

str

[in] String to insert.

Return Value

Resulted string length.

Insert

Inserts a string to the specified position from the CString class instance.

```
uint Insert(  
    uint      pos,      // position  
    CString*  str        // pointer  
)
```

Parameters

pos

[in] Position to insert into.

str

[in] Pointer to the CString class instance to insert.

Return Value

Resulted string length.

Compare

Compares to a string.

```
int Compare(  
    const string str    // string  
    ) const;
```

Parameters

str

[in] String to compare.

Return Value

0 - both strings are equal, -1 - the class string is lower than the string to compare, 1 - the class string is greater than the string to compare.

Compare

Compares to a CString class instance string.

```
int Compare(  
    CString* str        // pointer  
    ) const;
```

Parameters

str

[in] Pointer to CString class instance to compare.

Return Value

0 - strings are equal, -1 - the class string is lower than the string to compare, 1 - the class string is greater than the string to compare.

CompareNoCase

Performs a case insensitive string comparison.

```
int CompareNoCase(  
    const string str      // string  
    ) const;
```

Parameters

str

[in] String to compare.

Return Value

0 - strings are equal, -1 - a class string is lower than a string to compare, 1 - a class string is greater than a string to compare.

CompareNoCase

Compares a string (case insensitive) to a CString class instance string.

```
int CompareNoCase(  
    CString* str          // pointer  
    ) const;
```

Parameters

str

[in] Pointer to CString class instance to compare.

Return Value

0 - if strings are equal, -1 - a class string is lower than a string to compare, 1 - a class string is greater than a string to compare.

Left

Gets a substring of a specified length from the beginning of a string.

```
string Left(  
    uint count    // length  
)
```

Parameters

count

[in] Substring length.

Return Value

Resulted substring.

Right

Gets a substring of a specified length from the end of a string.

```
string Right(  
    uint count    // length  
)
```

Parameters

count

[in] Substring length.

Return Value

Resulted substring.

Mid

Gets a substring of a specified length from a specified string position.

```
string Mid(  
    uint pos,           // position  
    uint count          // length  
)
```

Parameters

pos

[in] Substring position.

count

[in] Substring length.

Return Value

Resulted substring.

Trim

Removes all characters within a set (as well as ' ', '\t', '\r', '\n') at both ends of a string from this string.

```
int Trim(  
    const string targets    // set  
)
```

Parameters

targets

[in] Set of characters to remove.

Return Value

Number of removed characters.

Example:

```
///--- example for CString::Trim  
#include <Strings\String.mqh>  
///---  
void OnStart()  
{  
    CString str;  
    ///---  
    str.Assign(" \t\tABCD\r\n");  
    printf("Source string '%s'", str.Str());  
    ///---  
    str.Trim("DA-DA-DA");  
    printf("Result string '%s'", str.Str());  
}
```

TrimLeft

Removes all characters within a set (as well as ' ', '\t', '\r', '\n') at the beginning of a string from this string.

```
int TrimLeft(  
    const string targets    // set  
)
```

Parameters

targets

[in] Set of characters to remove.

Return Value

Number of characters removed.

TrimRight

Removes all characters within a set (as well as ' ', '\t', '\r', '\n') at the end of a string from this string.

```
int TrimRight(  
    const string targets    // set  
)
```

Parameters

targets

[in] Set of characters to remove.

Return Value

Number of characters removed.

Clear

Clears a string.

```
bool Clear()
```

Return Value

true - successful, false - cannot clear a string.

ToUpper

Converts all string characters to uppercase.

```
bool ToUpper ()
```

Return Value

true - successful, false - cannot convert to uppercase.

ToLower

Converts all string characters to lowercase.

```
bool ToLower ()
```

Return Value

true - successful, false - cannot convert to lowercase.

Reverse

Reverses a string (initial and final characters exchange places pair-wise).

```
void Reverse ()
```

Find

Searches for the first match of a substring from a specified position.

```
int Find(  
    uint      start,          // position  
    const string substring    // substring  
) const;
```

Parameters

start

[in] Initial position for substring search.

substring

[in] Sample substring to search for.

Return Value

The index of the first match of a substring (-1 - substring is not found).

FindRev

Searches for the last match of a substring.

```
int FindRev(  
    const string substring    // substring  
    ) const;
```

Parameters

substring

[in] Sample substring to search for.

Return Value

The index of the last match of a substring (-1 - substring is not found).

Remove

Removes all substring matches.

```
uint Remove(  
    const string substring // substring  
)
```

Parameters

substring

[in] Sample substring to search for.

Return Value

Number of substring removals.

Replace

Replaces all substring matches.

```
uint Replace(  
    const string  substring,    // substring  
    const string  newstring     // substring  
)
```

Parameters

substring

[in] Sample substring to search for.

newstring

[in] Sample substring to replace with.

Return Value

Number of substring replacements.

Graphic Objects

This section contains the technical details of working with classes of graphical objects and a description of the relevant components of the MQL5 Standard Library.

The use of classes of graphical objects will save time when creating custom programs (scripts, Expert Advisors).

MQL5 Standard Library (in terms of graphical objects) is located in the working directory of the terminal in the Include\ChartObjects folder.

Class/Group	Description
<u>CChartObject</u>	Base class of a graphic object
<u>Lines</u>	Group classes "Lines"
<u>Channels</u>	Group classes "Channels"
<u>Gann Tools</u>	Group classes "Gann"
<u>Fibonacci Tools</u>	Group classes "Fibonacci"
<u>Elliott Tools</u>	Group classes "Elliott"
<u>Shapes</u>	Group classes "Shapes"
<u>Arrows</u>	Group classes "Arrows"
<u>Controls</u>	Group classes "Controls"

CChartObject

CChartObject is a base class for the classes of chart graphical objects of the Standard MQL5 library.

Description

CChartObject class provides the simplified access to MQL5 API functions for all of its descendants.

Declaration

```
class CChartObject : public CObject
```

Title

```
#include <ChartObjects\ChartObject.mqh>
```

Inheritance hierarchy

[CObject](#)

CChartObject

Direct descendants

[CChartObjectArrow](#), [CChartObjectBitmap](#), [CChartObjectBmpLabel](#), [CChartObjectCycles](#),
[CChartObjectElliottWave3](#), [CChartObjectEllipse](#), [CChartObjectFiboArc](#), [CChartObjectFiboFan](#),
[CChartObjectFiboTimes](#), [CChartObjectHLine](#), [CChartObjectRectangle](#), [CChartObjectSubChart](#),
[CChartObjectText](#), [CChartObjectTrend](#), [CChartObjectTriangle](#), [CChartObjectVLine](#)

Class Methods by Groups

Attributes	
ChartId	Gets the ID of the chart a graphical object belongs to
Window	Gets the number of a chart window where a graphical object is located
Name	Gets/sets the name of a graphical object
NumPoints	Gets the number of anchor points
Assign	
Attach	Binds a chart graphical object
SetPoint	Sets the anchor point parameters
Delete	
Delete	Deletes a chart graphical object
Detach	Detaches a chart graphical object
Shift	

<u>ShiftObject</u>	The relative object shift
<u>ShiftPoint</u>	The relative object point shift
Object properties	
<u>Time</u>	Gets/sets the time coordinates of an object point
<u>Price</u>	Gets/sets the price coordinate of an object point
<u>Color</u>	Gets/sets the color of the object
<u>Style</u>	Gets/sets the object line style
<u>Width</u>	Gets/sets the object line width
<u>BackGround</u>	Gets/sets the flag of drawing an object in the background
<u>Selected</u>	Gets/sets the "selected" flag of a graphical object
<u>Selectable</u>	Gets/sets the selectable object flag
<u>Description</u>	Gets/sets the text of the object
<u>Tooltip</u>	Gets/sets the tooltip of the object
<u>Timeframes</u>	Gets/sets the mask of the object visibility flags
<u>Z_Order</u>	Gets/sets the graphical object priority for receiving an event of mouse clicking on a chart
<u>CreateTime</u>	Gets the time of the object creation
Object level properties	
<u>LevelsCount</u>	Gets/sets the number of object levels
<u>LevelColor</u>	Gets/sets the level line color
<u>LevelStyle</u>	Gets/sets the level line style
<u>LevelWidth</u>	Gets/sets the level line width
<u>LevelValue</u>	Gets/sets the level
<u>LevelDescription</u>	Gets/sets the level text
Access to API MQL5 functions	
<u>GetInteger</u>	Gets the value of the object property
<u>SetInteger</u>	Sets the value of the object property
<u>GetDouble</u>	Gets the value of the object property
<u>SetDouble</u>	Sets the value of the object property

GetString	Gets the value of the object property
SetString	Sets the value of the object property
Input/Output	
virtual Save	Virtual method of writing to a file
virtual Load	Virtual method of reading from a file
virtual Type	Virtual method of identification

Methods inherited from class CObject

Prev, Prev, Next, Next, [Compare](#)

ChartId

Gets the ID of the chart a graphical object belongs to.

```
long ChartId() const
```

Return Value

ID of the chart where the graphical object is located. If there is no bound object, it returns -1.

Example:

```
//--- example for CChartObject::ChartId
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
{
    CChartObject object;
    //--- get chart identifier of chart object
    long chart_id=object.ChartId();
}
```

Window

Gets the index of the chart window where the graphical object is located.

```
int Window() const
```

Return Value

The number of the chart window where the graphical object is located (0 - main window). If there is no bound object, it returns -1.

Example:

```
//--- example for CChartObject::Window
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
{
    CChartObject object;
    //--- get window of chart object
    int window=object.Window();
}
```

Name (Get Method)

Gets the name of the graphical object.

```
string Name() const
```

Return Value

Name of the graphical object attached to an instance of the class. If there is no attached object, it returns NULL.

Name (Set Method)

Sets the name of the graphical object.

```
bool Name (  
    string name      // new name  
)
```

Parameters

name

[in] The new name of the graphical object.

Return Value

true - success, false - cannot change the name.

Example:

```
//--- example for CChartObject::Name  
#include <ChartObjects\ChartObject.mqh>  
//---  
void OnStart()  
{  
    CChartObject object;  
    //--- get name of chart object  
    string object_name=object.Name();  
    if(object_name!="MyChartObject")  
    {  
        //--- set name of chart object  
        object.Name("MyChartObject");  
    }  
}
```

NumPoints

Gets the number of anchor points of a graphical object.

```
int NumPoints() const
```

Return Value

Number of points linking a graphical object attached to an instance of the class. If there is no attached object, it returns 0.

Example:

```
//--- example for CChartObject::NumPoints
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
{
    CChartObject object;
    //--- get points count of chart object
    int points=object.NumPoints();
}
```

Attach

Attaches a graphical object to an instance of the class.

```
bool Attach(  
    long    chart_id,      // chart ID  
    string  name,          // name of the object  
    int     window,        // chart window  
    int     points         // number of points  
)
```

Parameters

chart_id

[out] Chart identifier.

name

[in] Name of the graphical object.

window

[in] Chart window number (0 - main window).

points

[in] Number of anchor points of the graphical object.

Return Value

true - success, false - cannot bind the object.

Example:

```
///--- example for CChartObject::Attach  
#include <ChartObjects\ChartObject.mqh>  
///---  
void OnStart()  
{  
    CChartObject object;  
    ///--- attach chart object  
    if(!object.Attach(CharID(), "MyObject", 0, 2))  
    {  
        printf("Object attach error");  
        return;  
    }  
}
```

SetPoint

Sets new coordinates of the specified anchor point of the graphical object.

```
bool SetPoint(  
    int      point,          // point number  
    datetime new_time,       // time coordinate  
    double   new_price       // price coordinate  
)
```

Parameters

point

[in] Number of the graphical object anchor point.

new_time

[in] New value for the time coordinate of the specified anchor point.

new_price

[in] New value for price coordinate of the specified anchor point.

Return Value

true - success, false - cannot change coordinates of the point.

Example:

```
///--- example for CChartObject::SetPoint  
#include <ChartObjects\ChartObject.mqh>  
///---  
void OnStart()  
{  
    CChartObject object;  
    double       price;  
    ///---  
    if(object.NumPoints()>0)  
    {  
        ///--- set point of chart object  
        object.SetPoint(0,CurrTime(),price);  
    }  
}
```

Delete

Removes an attached graphical object from the chart.

```
bool Delete()
```

Return Value

true - success, false - cannot remove the object.

Example:

```
//--- example for CChartObject::Delete
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
{
    CChartObject object;
    //--- detach chart object
    if(!object.Delete())
    {
        printf("Object delete error");
        return;
    }
}
```

Detach

Detaches the graphical object.

```
void Detach()
```

Return Value

None.

Example:

```
//--- example for CChartObject::Detach
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
{
    CChartObject object;
    //--- detach chart object
    object.Detach();
}
```

ShiftObject

Shifts a graphical object.

```
bool ShiftObject(  
    datetime d_time,      // increment of time coordinate  
    double   d_price      // increment of price coordinate  
)
```

Parameters

d_time

[in] Increment of the time coordinate of all anchor points.

d_price

[in] Increment of the price coordinate of all anchor points.

Return Value

true - success, false - cannot shift the object.

Example:

```
//--- example for CChartObject::ShiftObject  
#include <ChartObjects\ChartObject.mqh>  
//---  
void OnStart()  
{  
    CChartObject object;  
    datetime   d_time;  
    double     d_price;  
    //--- shift chart object  
    object.ShiftObject(d_time,d_price);  
}
```

ShiftPoint

Shifts a specified anchor point of the graphical object.

```
bool ShiftPoint(  
    int      point,          // point number  
    datetime d_time,        // increment of time coordinate  
    double   d_price         // increment of price coordinate  
)
```

Parameters

point

[in] Number of a graphical object anchor point.

d_time

[in] Increment of the time coordinate of the specified point.

d_price

[in] Increment of the price coordinate of the specified point.

Return Value

true - success, false - cannot shift the point.

Example:

```
///--- example for CChartObject::ShiftPoint  
#include <ChartObjects\ChartObject.mqh>  
///---  
void OnStart()  
{  
    CChartObject object;  
    datetime      d_time;  
    double        d_price;  
    ///---  
    if(object.NumPoints()>0)  
    {  
        ///--- shift point of chart object  
        object.ShiftPoint(0,d_time,d_price);  
    }  
}
```

Time (Get Method)

Gets the time coordinate of the specified anchor point of a graphical object.

```
datetime Time(  
    int point      // point number  
) const
```

Parameters

point

[in] Number of a graphical object anchor point.

Return Value

Time coordinate of the specified anchor point of the graphical object attached to an instance of the class. If there is no attached object or the object does not have this point, it returns 0.

Time (Set Method)

Sets the time coordinate of the specified anchor point of a graphical object.

```
bool Time(  
    int point,      // point number  
    datetime new_time // time  
)
```

Parameters

point

[in] Number of a graphical object anchor point.

new_time

[in] New value for the time coordinate of the specified graphical object anchor point.

Return Value

true - success, false - cannot change the time coordinate.

Example:

```
///--- example for CChartObject::Time  
#include <ChartObjects\ChartObject.mqh>  
///---  
void OnStart()  
{  
    CChartObject object;  
    ///---  
    for(int i=0;i<object.NumPoints();i++)  
    {  
        ///--- get time of the chart object point  
        datetime point_time=object.Time(i);  
        if(point_time==0)
```

```
{  
    //--- set time of the chart object point  
    object.Time(i,TimeCurrent());  
}  
}  
}
```

Price (Get Method)

Gets the price coordinate of the specified anchor point of a graphical object.

```
double Price(  
    int point    // point number  
) const
```

Parameters

point

[in] Number of a graphical object anchor point.

Return Value

Price coordinate of the specified anchor point of the graphical object attached to an instance of the class. If there is no attached object or the object does not have this point, it returns [EMPTY_VALUE](#).

Price (Set Method)

Sets the price coordinate of the specified anchor point of a graphical object.

```
bool Price(  
    int point,      // point number  
    double new_price // price  
)
```

Parameters

point

[in] Number of a graphical object anchor point.

new_price

[in] New value for the price coordinate of the specified graphical object anchor point.

Return Value

true - success, false - cannot change the price coordinate.

Example:

```
///--- example for CChartObject::Price  
#include <ChartObjects\ChartObject.mqh>  
///---  
void OnStart()  
{  
    CChartObject object;  
    double price;  
    ///---  
    for(int i=0;i<object.NumPoints();i++)  
    {  
        ///--- get price of the chart object point  
        double point_price=object.Price(i);
```

```
if(point_price!=price)
{
    ///--- set price for the chart object point
    object.Price(i,price);
}
}
```

Color (Get Method)

Gets the line color of the graphical object.

```
color Color() const
```

Return Value

Line color of the graphical object attached to the class instance. If there is no object attached, it returns CLR_NONE.

Color (Set Method)

Sets the line color of the graphical object.

```
bool Color(  
    color new_color    // new color  
)
```

Parameters

new_color

[in] New value of a graphical object line color.

Return Value

true - success, false - cannot change the color.

Example:

```
///--- example for CChartObject::Color  
#include <ChartObjects\ChartObject.mqh>  
///---  
void OnStart()  
{  
    CChartObject object;  
    ///--- get color of chart object  
    color object_color=object.Color();  
    if(object_color!=clrRed)  
    {  
        ///--- set color of chart object  
        object.Color(clrRed);  
    }  
}
```

Style (Get Method)

Gets the line style of the graphical object.

```
ENUM_LINE_STYLE Style() const
```

Return Value

Line style of the graphical object attached to the class instance. If there is no attached object, it returns WRONG_VALUE.

Style (Set Method)

Sets the line style of the graphical object.

```
bool Style(  
    ENUM_LINE_STYLE new_style    // style  
)
```

Parameters

new_style

[in] New value of the graphical object line style.

Return Value

true - success, false - cannot change the style.

Example:

```
//--- example for CChartObject::Style  
#include <ChartObjects\ChartObject.mqh>  
//---  
void OnStart()  
{  
    CChartObject object;  
    //--- get style of chart object  
    ENUM_LINE_STYLE style=object.Style();  
    if(style!=STYLE_SOLID)  
    {  
        //--- set style of chart object  
        object.Style(STYLE_SOLID);  
    }  
}
```

Width (Get Method)

Gets the line width of the graphical object.

```
int Width() const
```

Return Value

The line width of the graphical object attached to an instance of the class. If there is no attached object, it returns -1.

Width (Set Method)

Sets the line width of the graphical object.

```
bool Width(  
    int new_width    // thickness  
)
```

Parameters

new_width

[in] New value of the graphical object line width.

Return Value

true - success, false - cannot change the width.

Example:

```
///--- example for CChartObject::Width  
#include <ChartObjects\ChartObject.mqh>  
///---  
void OnStart()  
{  
    CChartObject object;  
    ///--- get width of chart object  
    int width=object.Width();  
    if(width!=1)  
    {  
        ///--- set width of chart object  
        object.Width(1);  
    }  
}
```

Background (Get Method)

Gets the flag for drawing a graphical object on the background.

```
bool Background() const
```

Return Value

Flag for drawing the graphical object, attached to an instance of the class, on the background. If there is no attached object, returns false.

Background (Set Method)

Sets the flag for drawing a graphical object on the background.

```
bool Background(  
    bool background    // value of the flag  
)
```

Parameters

background

[in] New value of the flag for drawing a graphical object on the background.

Return Value

true - success, false - cannot change the flag.

Example:

```
///--- example for CChartObject::Background  
#include <ChartObjects\ChartObject.mqh>  
///---  
void OnStart()  
{  
    CChartObject object;  
    ///--- get background flag of chart object  
    bool background_flag=object.Background();  
    if(!background_flag)  
    {  
        ///--- set background flag of chart object  
        object.Background(true);  
    }  
}
```

Selected (Get Method)

Gets the flag indicating that a graphical object is selected. In other words - if the graphical object is selected or not.

```
bool Selected() const
```

Return Value

The state that the object, attached to an instance of the class, is selected. If there is no attached object, returns false.

Selected (Set Method)

Sets the flag indicating that the graphical object is selected.

```
bool Selected(  
    bool selected    // value of the flag  
)
```

Parameters

selected

[in] New value of the flag indicating that a graphical object is selected.

Return Value

true - success, false - cannot change the flag.

Example:

```
//--- example for CChartObject::Selected  
#include <ChartObjects\ChartObject.mqh>  
//---  
void OnStart()  
{  
    CChartObject object;  
    //--- get the "selected" flag of chart object  
    bool selected_flag=object.Selected();  
    if(selected_flag)  
    {  
        //--- set the "selected" flag of chart object  
        object.Selected(false);  
    }  
}
```

Selectable (Get Method)

Gets the flag indicating an ability of a graphical object to be selected. In other words - if the graphical object can be selected or not.

```
bool Selectable() const
```

Return Value

Flag indicating the ability of the graphical object, attached to an instance of the class, to be selected. If there is no attached object, returns false.

Selectable (Set Method)

Sets the flag indicating the ability of a graphical object to be selected.

```
bool Selectable(  
    bool selectable    // value of the flag  
)
```

Parameters

selectable

[in] New value of the flag indicating an ability of a graphical object to be selected.

Return Value

true - success, false - cannot change the flag.

Example:

```
//--- example for CChartObject::Selectable  
#include <ChartObjects\ChartObject.mqh>  
//---  
void OnStart()  
{  
    CChartObject object;  
    //--- get the "selectable" flag of chart object  
    bool selectable_flag=object.Selectable();  
    if(selectable_flag)  
    {  
        //--- set the "selectable" flag of chart object  
        object.Selectable(false);  
    }  
}
```

Description (Get Method)

Gets a description (text) of a graphical object.

```
string Description() const
```

Return Value

Description (text) of the graphical object attached to an instance of the class. If there is no attached object, it returns NULL.

Description (Set Method)

Sets the description (text) of the graphical object.

```
bool Description(  
    string text    // text  
)
```

Parameters

text

[in] New description (text) of a graphical object.

Return Value

true - success, false - cannot change the description (text).

Example:

```
///--- example for CChartObject::Description  
#include <ChartObjects\ChartObject.mqh>  
///---  
void OnStart()  
{  
    CChartObject object;  
    ///--- get description of chart object  
    string description=object.Description();  
    if(description=="")  
    {  
        ///--- set description of chart object  
        object.Description("MyObject");  
    }  
}
```

Tooltip (Get Method)

Gets the tooltip text of a graphical object.

```
string Tooltip() const
```

Return Value

The text of a tooltip of the graphical object attached to an instance of the class. If there is no attached object, it returns NULL.

Tooltip (Set Method)

Sets the text of the tooltip of a graphical object.

```
bool Tooltip(  
    string new_tooltip    // new text of a tooltip  
)
```

Parameters

new_tooltip

[in] New text of a graphical object tooltip.

Return Value

true - success, false - cannot change the tooltip.

Note:

If the property is not set, then the tooltip generated automatically by the terminal is shown. A tooltip can be disabled by setting the "\n" (line feed) value.

Timeframes (Get Method)

Gets visibility flags of a graphical object.

```
int Timeframes() const
```

Return Value

Visibility flags of the graphical object attached to an instance of the class. If there is no attached object, it returns 0.

Timeframes (Set Method)

Sets visibility flags of a graphical object.

```
bool Timeframes (
    int new_timeframes    // visibility flags
)
```

Parameters

new_timeframes

[in] New visibility flags of the graphical object.

Return Value

true - success, false - cannot change the flags of visibility.

Example:

```
///--- example for CChartObject::Timeframes
#include <ChartObjects\ChartObject.mqh>
///---
void OnStart()
{
    CChartObject object;
    ///--- get timeframes of chart object
    int timeframes=object.Timeframes();
    if(!(timeframes&OBJ_PERIOD_H1))
    {
        ///--- set timeframes of chart object
        object.Timeframes(timeframes|OBJ_PERIOD_H1);
    }
}
```

Z_Order (Get Method)

Gets the graphical object priority for receiving an event of mouse clicking on a chart ([CHARTEVENT_CLICK](#)).

```
long Z_Order() const
```

Return Value

Priority of a graphical object, attached to the class instance. If there is no object attached, it returns 0.

Z_Order (Set Method)

Sets the graphical object priority for receiving an event of mouse clicking on a chart ([CHARTEVENT_CLICK](#)).

```
bool Z_Order(  
    long value    // graphical object priority  
)
```

Parameters

value

[in] New value of priority of a graphical object for receiving the event [CHARTEVENT_CLICK](#).

Return Value

true - success, false - cannot change the priority.

Note

Z_Order property manages a priority when handling clicks on graphical objects. By setting the value greater than 0 (default value), you can increase the object priority when handling mouse clicks.

CreateTime

Gets the graphical object creation time.

```
datetime CreateTime() const
```

Return Value

Creation time of the graphical object attached to the instance of the class. If there is no attached object, it returns 0.

Example:

```
//--- example for CChartObject::CreateTime
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
{
    CChartObject object;
    //--- get create time of chart object
    datetime create_time=object.CreateTime();
}
```

LevelsCount (Get Method)

Gets the number of levels of a graphical object.

```
int LevelsCount() const
```

Return Value

Number of levels of the graphical object attached to an instance of the class. If there is no attached object, it returns 0.

LevelsCount (Set Method)

Sets the number of levels of the graphical object.

```
bool LevelsCount(  
    int levels    // number of levels  
)
```

Parameters

levels

[in] The new number of levels of the graphical object.

Return Value

true - success, false - cannot change the number of levels.

Example:

```
//--- example for CChartObject::LevelsCount  
#include <ChartObjects\ChartObject.mqh>  
//---  
void OnStart()  
{  
    CChartObject object;  
    //--- get levels count of chart object  
    int levels_count=object.LevelsCount();  
    //--- set levels count of chart object  
    object.LevelsCount(levels_count+1);  
}
```

LevelColor (Get Method)

Gets the line color of the specified level of a graphical object.

```
color LevelColor(  
    int level    // level number  
) const
```

Parameters

level

[in] Number of graphical object level.

Return Value

Line color of the specified level of the graphical object attached to the instance of the class. If there is no attached object or the object does not have the specified level, it returns CLR_NONE.

LevelColor (Set Method)

Sets the line color of the specified level of the graphical object.

```
bool LevelColor(  
    int level,        // level number  
    color new_color    // new color  
)
```

Parameters

level

[in] Number of graphical object level.

new_color

[in] New line color of the specified level of a graphical object.

Return Value

true - success, false - cannot change the color.

Example:

```
///--- example for CChartObject::LevelColor  
#include <ChartObjects\ChartObject.mqh>  
///---  
void OnStart()  
{  
    CChartObject object;  
    ///---  
    for(int i=0;i<object.LevelsCount();i++)  
    {  
        ///--- get level color of chart object  
        color level_color=object.LevelColor(i);  
        if(level_color!=clrRed)
```

```
{  
    //--- set level color of chart object  
    object.LevelColor(i,clrRed);  
}  
}  
}
```

LevelStyle (Get Method)

Gets the line style of the specified level of a graphical object.

```
ENUM_LINE_STYLE LevelStyle(  
    int level    // level number  
) const
```

Parameters

level

[in] Number of graphical object level.

Return Value

Line style of the specified level of the graphical object attached to an instance of the class. If there is no attached object or the object does not have the specified level, it returns WRONG_VALUE.

LevelStyle (Set Method)

Sets the line style of the specified level of the graphic object.

```
int LevelStyle(  
    int level,    // level number  
    ENUM_LINE_STYLE style // line style  
)
```

Parameters

level

[in] Number of graphical object level.

style

[in] New line style of the specified level of a graphical object.

Return Value

true - success, false - cannot change the style.

Example:

```
//--- example for CChartObject::LevelStyle  
#include <ChartObjects\ChartObject.mqh>  
//---  
void OnStart()  
{  
    CChartObject object;  
    //---  
    for(int i=0;i<object.LevelsCount();i++)  
    {  
        //--- get level style of chart object  
        ENUM_LINE_STYLE level_style=object.LevelStyle(i);  
        if(level_style!=STYLE_SOLID)
```

```
{  
    //--- set level style of chart object  
    object.LevelStyle(i,STYLE_SOLID);  
}  
}  
}
```

LevelWidth (Get Method)

Gets the line width of the specified level of a graphical object.

```
int LevelWidth(  
    int level    // level number  
) const
```

Parameters

level

[in] Number of graphical object level.

Return Value

Line width of the specified level of the graphical object attached to the instance of the class. If there is no attached object or the object does not have the specified level, it returns -1.

LevelWidth (Set Method)

Sets the line width of the specified level of the graphical object.

```
bool LevelWidth(  
    int level,        // level number  
    int new_width     // new width  
)
```

Parameters

level

[in] Number of graphical object level.

new_width

[in] New line width of the specified level of a graphical object.

Return Value

true - success, false - cannot change the width.

Example:

```
//--- example for CChartObject::LevelWidth  
#include <ChartObjects\ChartObject.mqh>  
//---  
void OnStart()  
{  
    CChartObject object;  
    //---  
    for(int i=0;i<object.LevelsCount();i++)  
    {  
        //--- get level width of chart object  
        int level_width=object.LevelWidth(i);  
        if(level_width!=1)
```

```
{  
    //--- set level width of chart object  
    object.LevelWidth(i,1);  
}  
}  
}
```

LevelValue (Get Method)

Gets the value of the specified level of a graphical object.

```
double LevelValue(  
    int level    // level number  
) const
```

Parameters

level

[in] Number of a graphical object level.

Return Value

The value of the specified level of a graphical object that is bound to an instance of the class. If there is no bound object or the object has no level specified, returns [EMPTY_VALUE](#).

LevelValue (Set Method)

Sets the value of the specified level of the graphical object.

```
bool LevelValue(  
    int level,        // level number  
    double new_value  // new value  
)
```

Parameters

level

[in] Number of a graphical object level.

new_value

[in] New value of the specified level of a graphical object.

Return Value

true - successful, false - cannot change the value.

Example:

```
//--- example for CChartObject::LevelValue  
#include <ChartObjects\ChartObject.mqh>  
//---  
void OnStart()  
{  
    CChartObject object;  
    //---  
    for(int i=0;i<object.LevelsCount();i++)  
    {  
        //--- get level value of chart object  
        double level_value=object.LevelValue(i);  
        if(level_value!=0.1*i)
```

```
{  
    //--- set level value of chart object  
    object.LevelValue(i,0.1*i);  
}  
}  
}
```

LevelDescription (Get Method)

Gets a description (text) of the level of a graphical object.

```
string LevelDescription(  
    int level      // level number  
) const
```

Parameters

level

[in] Number of a graphical object level.

Return Value

Description (text) of the specified level of a graphical object that is bound to an instance of the class. Returns NULL if there is no bound object or the object has no specified level.

LevelDescription (Set Method)

Sets the description (text) of the specified graphical object level.

```
bool LevelDescription(  
    int level,      // level number  
    string text     // text  
)
```

Parameters

level

[in] Number of a graphical object level.

text

[in] New value of description (text) of the specified graphical object level.

Return Value

true - success, false - cannot change the description (text).

Example:

```
///--- example for CChartObject::LevelDescription  
#include <ChartObjects\ChartObject.mqh>  
///---  
void OnStart()  
{  
    CChartObject object;  
    ///---  
    for(int i=0;i<object.LevelsCount();i++)  
    {  
        ///--- get level description of chart object  
        string level_description=object.LevelDescription(i);  
        if(level_description=="")
```

```
{  
    ///--- set level description of chart object  
    object.LevelDescription(i,"Level_"+IntegerToString(i));  
}  
}  
}
```

GetInteger

Provides simplified access to the functions of API MQL5 [ObjectGetInteger\(\)](#) to receive values of integer properties (of bool, char, uchar, short, ushort, int, uint, long, ulong, datetime, color types) of a graphical object bound to a class instance. There are two versions of the function call:

Getting a property value without checking the correctness

```
long GetInteger (
    ENUM_OBJECT_PROPERTY_INTEGER prop_id,      // integer property ID
    int modifier=-1                          // modifier
) const
```

Parameters

prop_id

[in] ID of the graphical object double property.

modifier=-1

[in] Modifier (index) of a double property.

Return Value

Value of an integer property - success, 0 - cannot receive an integer property.

Getting a property value verifying the correctness of the operation

```
bool GetInteger (
    ENUM_OBJECT_PROPERTY_INTEGER prop_id,      // integer property ID
    int modifier,                             // modifier
    long& value                               // link to a variable
) const
```

Parameters

prop_id

[in] ID of a graphical object integer property.

modifier

[in] Modifier (index) of an integer property.

value

[out] Link to a variable to place an integer property value.

Return Value

true - success, false - cannot get an integer property.

Example:

```
///--- example for CChartObject::GetInteger
#include <ChartObjects\ChartObject.mqh>
///---
void OnStart ()
```

```
{
    CChartObject object;
    //--- get color of chart object by easy method
    printf("Objects color is %s",ColorToString(object.GetInteger(OBJPROP_COLOR),true));
    //--- get color of chart object by classic method
    long color_value;
    if(!object.GetInteger(OBJPROP_COLOR,0,color_value))
    {
        printf("Get integer property error %d",GetLastError());
        return;
    }
    else
        printf("Objects color is %s",color_value);
    for(int i=0;i<object.LevelsCount();i++)
    {
        //--- get levels width by easy method
        printf("Level %d width is %d",i,object.GetInteger(OBJPROP_LEVELWIDTH,i));
        //--- get levels width by classic method
        long width_value;
        if(!object.GetInteger(OBJPROP_LEVELWIDTH,i,width_value))
        {
            printf("Get integer property error %d",GetLastError());
            return;
        }
        else
            printf("Level %d width is %d",i,width_value);
    }
}
```

SetInteger

Provides simplified access to the functions of API MQL5 [ObjectSetInteger\(\)](#) to change integer properties (of type bool, char, uchar, short, ushort, int, uint, long, ulong, datetime, color types) of a graphical object bound to class instance. There are two versions of the function call:

Setting a property value that does not require a modifier

```
bool SetInteger (
    ENUM_OBJECT_PROPERTY_INTEGER prop_id,    // integer property ID
    long value                                // value
)
```

Parameters

prop_id

[in] ID of a graphical object integer property.

value

[in] New value of a changed integer property.

Setting a property value indicating the modifier

```
bool SetInteger (
    ENUM_OBJECT_PROPERTY_INTEGER prop_id,    // integer property ID
    int modifier,                            // modifier
    long value                                // value
)
```

Parameters

prop_id

[in] ID of a graphical object integer property.

modifier

[in] Modifier (index) of an integer property.

value

[in] New value of an integer property.

Return Value

true - success, false - cannot change the integer property.

Example:

```
///--- example for CChartObject::SetInteger
#include <ChartObjects\ChartObject.mqh>
///---
void OnStart ()
{
    CChartObject object;
    ///--- set new color of chart object
```

```
if(!object.SetInteger(OBJPROP_COLOR,clrRed))
{
    printf("Set integer property error %d",GetLastError());
    return;
}
for(int i=0;i<object.LevelsCount();i++)
{
    //--- set levels width
    if(!object.SetInteger(OBJPROP_LEVELWIDTH,i,i))
    {
        printf("Set integer property error %d",GetLastError());
        return;
    }
}
}
```

GetDouble

Provides simplified access to the functions of API MQL5 [ObjectGetDouble\(\)](#) to receive double values (of float and double types) of a graphical object bound to a class instance. There are two versions of the function call:

Getting a property value without checking the correctness

```
double  GetDouble (
    ENUM_OBJECT_PROPERTY_DOUBLE prop_id,      // integer property ID
    int      modifier=-1                      // modifier
) const
```

Parameters

prop_id
[in] ID of the graphical object double property.

modifier=-1
[in] Modifier (index) of a double property.

Return Value

Value of a double property - success, [EMPTY_VALUE](#) - cannot receive a double property.

Getting a property value in verifying the correctness of such treatment

```
bool  GetDouble (
    ENUM_OBJECT_PROPERTY_DOUBLE prop_id,      // double property ID
    int      modifier,                      // modifier
    double&   value                        // link to a variable
) const
```

Parameters

prop_id
[in] ID of a graphical object double property.

modifier
[in] Modifier (index) of a double property.

value
[out] Link to a variable to place a double property value.

Return Value

true - success, false - cannot get a double property.

Example:

```
//--- example for CChartObject::GetDouble
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart ()
```

```
{
    CChartObject object;
    ///---
    for(int i=0;i<object.LevelsCount();i++)
    {
        ///--- get levels value by easy method
        printf("Level %d value=%f",i,object.GetDouble(OBJPROP_LEVELVALUE,i));
        ///--- get levels value by classic method
        double value;
        if(!object.SetDouble(OBJPROP_LEVELVALUE,i,value))
        {
            printf("Get double property error %d",GetLastError());
            return;
        }
        else
            printf("Level %d value=%f",i,value);
    }
}
```

SetDouble

Provides simplified access to the functions of API MQL5 [ObjectSetDouble\(\)](#) to change double properties (of float and double types) of a graphical object bound to a class instance. There are two versions of a function call:

Setting a property value that does not require a modifier

```
bool SetDouble (
    ENUM_OBJECT_PROPERTY_DOUBLE prop_id,    // double property ID
    double value                             // value
)
```

Parameters

prop_id

[in] ID of a graphical object double property.

value

[in] New value of a changed double property.

Setting a property value indicating the modifier

```
bool SetDouble (
    ENUM_OBJECT_PROPERTY_DOUBLE prop_id,    // double property ID
    int modifier,                          // modifier
    double value                             // value
)
```

Parameters

prop_id

[in] ID of a graphical object double property.

modifier

[in] Modifier (index) of a double property.

value

[in] New value of a changed double property.

Return Value

true - success, false - cannot change the double feature.

Example:

```
///--- example for CChartObject::SetDouble
#include <ChartObjects\ChartObject.mqh>
///---
void OnStart ()
{
    CChartObject object;
    ///---
```

```
for(int i=0;i<object.LevelsCount();i++)
{
    //--- set level value of chart object
    if(!object.SetDouble(OBJPROP_LEVELVALUE,i,0.1*i))
    {
        printf("Set double property error %d",GetLastError());
        return;
    }
}
}
```

GetString

Provides simplified access to the functions of API MQL5 [ObjectGetString\(\)](#) for string property values of a graphical object bound to a class instance. There are two versions of a function call:

Getting a property value without checking the correctness

```
string GetString(  
    ENUM_OBJECT_PROPERTY_STRING prop_id,      // string property ID  
    int modifier=-1                          // modifier  
) const
```

Parameters

prop_id

[in] ID of graphical object string property.

modifier=-1

[in] Modifier (index) of a string property.

Return Value

Value of a string property - success, "" - cannot receive a string property.

Getting a property value verifying the correctness of such treatment

```
bool GetString(  
    ENUM_OBJECT_PROPERTY_STRING prop_id,      // string property ID  
    int modifier,                          // modifier  
    string& value                          // link to a variable  
) const
```

Parameters

prop_id

[in] ID of a graphical object string property.

modifier

[in] Modifier (index) of a string property.

value

[out] Link to a variable to place a string property value.

Return Value

true - successful, false - cannot get a string property.

Example:

```
//--- example for CChartObject::GetString  
#include <ChartObjects\ChartObject.mqh>  
//---  
void OnStart()  
{
```

```
CChartObject object;
string      value;
//--- get name of chart object by easy method
printf("Object name is '%s'",object.GetString(OBJPROP_NAME));
//--- get name of chart object by classic method
if(!object.GetString(OBJPROP_NAME,0,value))
{
    printf("Get string property error %d",GetLastError());
    return;
}
else
    printf("Object name is '%s'",value);
for(int i=0;i<object.LevelsCount();i++)
{
    //--- get levels description by easy method
    printf("Level %d description is '%s'",i,object.GetString(OBJPROP_LEVELTEXT,i));
    //--- get levels description by classic method
    if(!object.GetString(OBJPROP_LEVELTEXT,i,value))
    {
        printf("Get string property error %d",GetLastError());
        return;
    }
    else
        printf("Level %d description is '%s'",i,value);
}
}
```

SetString

Provides simplified access to the functions of API MQL5 [ObjectSetString\(\)](#) for changing string properties of a graphical object bound to a class instance. There are two versions of a function call:

Setting a property value that does not require a modifier

```
bool SetString(  
    ENUM_OBJECT_PROPERTY_STRING prop_id,    // string property ID  
    string value                            // value  
)
```

Parameters

prop_id

[in] ID of a graphical object string property.

value

[in] New value of a changed string property.

Setting a property value indicating the modifier

```
bool SetString(  
    ENUM_OBJECT_PROPERTY_STRING prop_id,    // string property ID  
    int modifier,                          // modifier  
    string value                            // value  
)
```

Parameters

prop_id

[in] ID of a graphical object string property.

modifier

[in] Modifier (index) of a string property.

value

[in] New value of a changed string property.

Return Value

true - success, false - cannot change a string property.

Example:

```
///--- example for CChartObject::SetString  
#include <ChartObjects\ChartObject.mqh>  
///---  
void OnStart()  
{  
    CChartObject object;  
    ///--- set new name of chart object  
    if(!object.SetString(OBJPROP_NAME, "MyObject"))
```

```
{
    printf("Set string property error %d",GetLastError());
    return;
}
for(int i=0;i<object.LevelsCount();i++)
{
    ///--- set levels description
    if(!object.SetString(OBJPROP_LEVELTEXT,i,"Level_"+IntegerToString(i))
    {
        printf("Set string property error %d",GetLastError());
        return;
    }
}
}
```

Save

Saves parameters of the object in the file.

```
virtual bool Save(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] Handle of the file previously opened using the function FileOpen (...).

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CChartObject::Save  
#include <ChartObjects\ChartObject.mqh>  
//---  
void OnStart()  
{  
    int file_handle;  
    CChartObject object=new CChartObject;  
    //--- set object parameters  
    //--- . . .  
    //--- open file  
    file_handle=FileOpen("MyFile.bin",FILE_WRITE|FILE_BIN|FILE_ANSI);  
    if(file_handle>=0)  
    {  
        if(!object.Save(file_handle))  
        {  
            //--- file save error  
            printf("File save: Error %d!",GetLastError());  
            FileClose(file_handle);  
            //---  
            return;  
        }  
        FileClose(file_handle);  
    }  
}
```

Load

Loads the parameters of the object from the file.

```
virtual bool Load(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] handle of the file previously opened using the function `FileOpen (...)`.

Return Value

true - successfully completed, false - error.

Example:

```
//--- example for CChartObject::Load  
#include <ChartObjects\ChartObject.mqh>  
//---  
void OnStart()  
{  
    int file_handle;  
    CChartObject object;  
    //--- open file  
    file_handle=FileOpen("MyFile.bin",FILE_READ|FILE_BIN|FILE_ANSI);  
    if(file_handle>=0)  
    {  
        if(!object.Load(file_handle))  
        {  
            //--- file load error  
            printf("File load: Error %d!",GetLastError());  
            FileClose(file_handle);  
            //---  
            return;  
        }  
        FileClose(file_handle);  
    }  
    //--- use object  
    //--- . . .  
}
```

Type

Gets the graphical object type ID.

```
virtual int Type() const
```

Return Value

Object type ID (0x8888 for [CChartObject](#)).

Example:

```
//--- example for CChartObject::Type
#include <ChartObjects\ChartObject.mqh>
//---
void OnStart()
{
    CChartObject object;
    //--- get object type
    int type=object.Type();
}
```

Line Objects

A group of "Lines" graphical objects.

This section contains the technical details of working with a group of classes of "Lines" graphical objects and a description of the relevant components of the MQL5 Standard Library.

Class name	Object
CChartObjectVLine	"Vertical Line" graphical object
CChartObjectHLine	"Horizontal Line" graphical object
CChartObjectTrend	"Trend Line" graphical object
CChartObjectTrendByAngle	"Trend Line by Angle" graphical object
CChartObjectCycles	"Cyclic Lines" graphical object

See also

[Object types](#), [Graphic objects](#)

CChartObjectVLine

CChartObjectVLine is a class for simplified access to "Vertical Line" graphical object properties.

Description

CChartObjectVLine class provides access to "Vertical Line" object properties.

Declaration

```
class CChartObjectVLine : public CChartObject
```

Title

```
#include <ChartObjects\ChartObjectsLines.mqh>
```

Inheritance hierarchy

Class Methods by Groups

Create

Creates "Vertical Line" graphical object.

```
bool Create(  
    long      chart_id,      // chart identifier  
    string     name,         // object name  
    int        window,       // chart window  
    datetime   time          // time coordinate  
)
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time

[in] Time coordinate of the anchor point.

Return Value

true - successful, false - error.

Type

Returns graphical object type identifier.

```
int Type() const
```

Return Value

Object type identifier (OBJ_VLINE for [CChartObjectVLine](#)).

CChartObjectHLine

CChartObjectHLine is a class for simplified access to "Horizontal Line" graphical object properties.

Description

CChartObjectHLine class provides access to "Horizontal Line" object properties.

Declaration

```
class CChartObjectHLine : public CChartObject
```

Title

```
#include <ChartObjects\ChartObjectsLines.mqh>
```

[Object types](#), [Graphic objects](#)

Create

Creates "Horizontal Line" graphical object.

```
bool Create(  
    long    chart_id,    // chart identifier  
    string  name,        // object name  
    long    window,      // chart window  
    double  price        // price coordinate  
)
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

price

[in] Price coordinate of the anchor point.

Return Value

true - successful, false - error.

Type

Returns graphical object type identifier.

```
int Type() const
```

Return Value

Object type identifier (OBJ_HLINE for [CChartObjectHLine](#)).

CChartObjectTrend

CChartObjectTrend is a class for simplified access to "Trend Line" graphical object properties.

Description

CChartObjectTrend class provides access to "Trend Line" object properties.

Declaration

```
class CChartObjectTrend : public CChartObject
```

Title

[Object types](#), [Graphic objects](#)

Create

Creates "Trend Line" graphical object.

```
bool Create(  
    long      chart_id,      // chart identifier  
    string     name,         // object name  
    int       window,        // chart window  
    datetime  time1,         // 1st time coordinate  
    double    price1,        // 1st price coordinate  
    datetime  time2,         // 2nd time coordinate  
    double    price2         // 2nd price coordinate  
)
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time1

[in] Time coordinate of the first anchor point.

price1

[in] Price coordinate of the first anchor point.

time2

[in] Time coordinate of the second anchor point.

price2

[in] Price coordinate of the second anchor point.

Return Value

true - successful, false - error.

RayLeft (Get Method)

Gets the value of "Ray Left" property.

```
bool RayLeft () const
```

Return Value

The value of "Ray Left" property assigned to the class instance. If there is no object assigned, it returns false.

RayLeft (Set Method)

Sets new flag value for the "Ray Left" property.

```
bool RayLeft (  
    bool ray      // flag  
)
```

Parameters

ray

[in] New value of the "Ray Left" property.

Return Value

true - successful, false - cannot change flag.

RayRight (Get Method)

Gets the value of "Ray Right" property.

```
bool RayRight() const
```

Return Value

The value of "Ray Right" property, assigned to the class instance. If there is no object assigned, it returns false.

RayRight (Set Method)

Sets new flag value for the "Ray Right" property.

```
bool RayRight (
    bool ray      // flag
)
```

Parameters

ray

[in] New value of the "Ray Right" property.

Return Value

true - successful, false - cannot change flag.

Save

Saves object parameters to file.

```
virtual bool Save(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] handle of a file opened previously using the FileOpen(...) function.

Return Value

true - successful, false - error.

Load

Loads object parameters from file.

```
virtual bool Load(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] handle of file opened previously using the FileOpen(...) function.

Return Value

true - successful, false - error.

Type

Returns graphical object type identifier.

```
int Type() const
```

Return Value

Object type identifier (OBJ_TREND for [CChartObjectTrend](#)).

CChartObjectTrendByAngle

CChartObjectTrendByAngle is a class for simplified access to "Trend Line by Angle" graphical object properties.

Description

CChartObjectTrendByAngle class provides access to "Trend Line by Angle" object properties.

Declaration

```
class CChartObjectTrendByAngle : public CChartObjectTrend
```

Title

```
#include <ChartObjects\ChartObjectsLines.mqh>
```

Inheritance hierarchy

[Object types](#), [Graphic objects](#)

Create

Creates "Trend Line by Angle" graphical object.

```
bool Create(  
    long      chart_id,      // chart identifier  
    string    name,          // object name  
    long      window,        // chart window  
    datetime  time1,         // 1st time coordinate  
    double    price1,        // 1st price coordinate  
    datetime  time2,         // 2nd time coordinate  
    double    price2         // 2nd price coordinate  
)
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time1

[in] Time coordinate of the first anchor point.

price1

[in] Price coordinate of the first anchor point.

time2

[in] Time coordinate of the second anchor point.

price2

[in] Price coordinate of the second anchor point.

Return Value

true - successful, false - error.

Angle (Get Method)

Gets the value of "Angle" property.

```
double Angle() const
```

Return Value

The value of "Angle" property assigned to the class instance. If there is no object assigned, it returns EMPTY_VALUE.

Angle (Set Method)

Sets new value for the "Angle" property.

```
bool Angle(  
    double angle    // angle  
)
```

Parameters

angle

[in] New value of the "Angle" property.

Return Value

true - successful, false - cannot change the property.

Type

Returns graphical object type identifier.

```
int Type() const
```

Return Value

Object type identifier (OBJ_TRENDBYANGLE for [CChartObjectTrendByAngle](#)).

CChartObjectCycles

CChartObjectCycles is a class for simplified access to "Cyclic Lines" graphical object properties.

Description

CChartObjectCycles provides access to "Cyclic Lines" object properties.

Declaration

```
class CChartObjectCycles : public CChartObject
```

Title

```
#include <ChartObjects\ChartObjectsLines.mqh>
```

Inheritance hierarchy

Class Methods by Groups

Create	
Create	Creates "Cycle Lines" graphical object
Input/output	
virtual Type	Virtual method of identification

Methods inherited from class CObject

[Object types](#), [Graphic objects](#)

Create

Creates "Cyclic Lines" graphical object.

```
bool Create(  
    long      chart_id,      // chart identifier  
    string    name,          // object name  
    long      window,        // chart window  
    datetime  time1,         // 1st time coordinate  
    double    price1,        // 1st price coordinate  
    datetime  time2,         // 2nd time coordinate  
    double    price2         // 2nd price coordinate  
)
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time1

[in] Time coordinate of the first anchor point.

price1

[in] Price coordinate of the first anchor point.

time2

[in] Time coordinate of the second anchor point.

price2

[in] Price coordinate of the second anchor point.

Return Value

true - successful, false - error.

Type

Returns graphical object type identifier.

```
int Type() const
```

Return Value

Object type identifier (OBJ_CYCLES for [CChartObjectCycles](#)).

Channel Objects

A group of "Channels" graphical objects.

This section contains the technical details of working with a group of classes of "Channels" graphical objects and a description of the relevant components of the MQL5 Standard Library.

Class name	Object
CChartObjectChannel	"Equidistant Channel" graphical object
CChartObjectRegression	"Linear Regression Channel" graphical object
CChartObjectStdDevChannel	"Standard deviations Channel" graphical object
CChartObjectPitchfork	"Andrew's Pitchfork" graphical object

Create

Creates "Equidistant Channel" graphic object.

```
bool Create(  
    long      chart_id,      // chart identifier  
    string    name,          // object name  
    int       window,        // chart window  
    datetime  time1,         // time coordinate of the first anchor point  
    double    price1,        // price coordinate of the first anchor point  
    datetime  time2,         // time coordinate of the second anchor point  
    double    price2,        // price coordinate of the second anchor point  
    datetime  time3,         // time coordinate of the third anchor point  
    double    price3         // price coordinate of the third anchor point  
)
```

Parameters

chart_id

[in] Chart ID (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time1

[in] Time coordinate of the first anchor point.

price1

[in] Price coordinate of the first anchor point.

time2

[in] Time coordinate of the second anchor point.

price2

[in] Price coordinate of the second anchor point.

time3

[in] Time coordinate of the third anchor point.

price3

[in] Price coordinate of the third anchor point.

Return Value

true - successful, false - error.

Type

Returns graphical object type identifier.

```
int Type() const
```

Return Value

Object type identifier (OBJ_CHANNEL for [CChartObjectChannel](#)).

CChartObjectRegression

CChartObjectRegression is a class for simplified access to "Linear Regression Channel" graphical object properties.

Description

CChartObjectRegression class provides access to "Linear Regression Channel" object properties.

Declaration

```
class CChartObjectRegression : public CChartObjectTrend
```

Title

```
#include <ChartObjects\ChartObjectsChannels.mqh>
```

Create

Creates "Linear Regression Channel" graphical object.

```
bool Create(  
    long      chart_id,      // chart identifier  
    string     name,         // object name  
    long      window,        // chart window  
    datetime   time1,        // first time coordinate  
    datetime   time2         // second time coordinate  
)
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time1

[in] Time coordinate of the first anchor point.

time2

[in] Time coordinate of the second anchor point.

Return Value

true - successful, false - error.

Type

Returns graphical object type identifier.

```
int Type() const
```

Return Value

Object type identifier (OBJ_REGRESSION for [CChartObjectRegression](#)).

CChartObjectStdDevChannel

CChartObjectStdDevChannel is a class for simplified access to "Standard Deviation Channel" graphical object properties.

Description

CChartObjectStdDevChannel class provides access to "Standard Deviation Channel" object properties.

Declaration

```
class CChartObjectStdDevChannel : public CChartObjectTrend
```

Title

```
#include <ChartObjects\ChartObjectsChannels.mqh>
```

Create

Creates "Standard Deviation Channel" graphical object.

```
bool Create(  
    long      chart_id,      // chart identifier  
    string     name,         // object name  
    int        window,       // chart window  
    datetime   time1,        // first time coordinate  
    datetime   time2,        // second time coordinate  
    double     deviation     // deviation  
)
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time1

[in] Time coordinate of the first anchor point.

time2

[in] Time coordinate of the second anchor point.

deviation

[in] Numerical value for "Deviation" property.

Return Value

true - successful, false - error.

Deviation (Get Method)

Gets "Deviation" property value.

```
double Deviation() const
```

Return Value

Value of "Deviation" property assigned to the class instance. If there is no object assigned, it returns EMPTY_VALUE.

Deviation (Set Method)

Sets "Deviation" property value.

```
bool Deviation(  
    double deviation    // deviation  
)
```

Parameters

deviation

[in] New value for "Deviation" property.

Return Value

true - successful, false - cannot change the property.

Save

Saves object parameters to file.

```
virtual bool Save(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] handle of file opened previously using the FileOpen(...) function.

Return Value

true - successful, false - error.

Load

Loads object parameters from file.

```
virtual bool Load(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] handle of file opened previously using the FileOpen(...) function.

Return Value

true - successful, false - error.

Type

Returns graphical object type identifier.

```
int Type() const
```

Return Value

Object type identifier (OBJ_STDDEVCHANNEL for [CChartObjectStdDevChannel](#)).

CChartObjectPitchfork

CChartObjectPitchfork is a class for simplified access to "Andrew's Pitchfork" graphical object properties.

Description

CChartObjectPitchfork class provides access to "Andrew's Pitchfork" object properties.

Declaration

```
class CChartObjectPitchfork : public CChartObjectTrend
```

Title

```
#include <ChartObjects\ChartObjectsChannels.mqh>
```

Create

Creates "Andrew's Pitchfork" graphical object.

```
bool Create(  
    long      chart_id,      // chart identifier  
    string     name,         // object name  
    long      window,        // chart window  
    datetime  time1,         // time coordinate of the first anchor point  
    double    price1,        // price coordinate of the first anchor point  
    datetime  time2,         // time coordinate of the second anchor point  
    double    price2,        // price coordinate of the second anchor point  
    datetime  time3,         // time coordinate of the third anchor point  
    double    price3         // price coordinate of the third anchor point  
)
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] Unique name of the object to create.

window

[in] Chart window number (0 - main window).

time1

[in] Time coordinate of the first anchor point.

price1

[in] Price coordinate of the first anchor point.

time2

[in] Time coordinate of the second anchor point.

price2

[in] Price coordinate of the second anchor point.

time3

[in] Time coordinate of the third anchor point.

price3

[in] Price coordinate of the third anchor point.

Return Value

true - successful, false - error.

Type

Returns graphical object type identifier.

```
int Type() const
```

Return Value

Object type identifier (OBJ_PITCHFORK for [CChartObjectPitchfork](#)).

Gann Tools

Create

Creates "Gann Line" graphical object.

```
bool Create(  
    long      chart_id,      // chart identifier  
    string     name,         // object name  
    int       window,        // chart window  
    datetime  time1,         // first time coordinate  
    double    price1,        // first price coordinate  
    datetime  time2,         // second time coordinate  
    double    ppb            // pips per bar  
)
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time1

[in] Time coordinate of the first anchor point.

price1

[in] Price coordinate of the first anchor point.

time2

[in] Time coordinate of the second anchor point.

ppb

[in] Pips per bar.

Return Value

true - successful, false - error.

PipsPerBar (Get Method)

Gets the value of "Pips per bar" property.

```
double PipsPerBar() const
```

Return Value

Value of "Pips per bar" property of the object assigned to the class instance. If there is no object assigned, it returns [EMPTY_VALUE](#).

PipsPerBar (Set Method)

Sets new value for "Pips per bar" property.

```
bool PipsPerBar(  
    double ppb      // pips per bar  
)
```

Parameters

ppb

[in] New value for "Pips per bar" property.

Return Value

true - successful, false - cannot change the property.

Save

Saves object parameters to file.

```
virtual bool Save(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] handle of the binary file already opened using the FileOpen(...) function

Return Value

true - successful, false - error.

Load

Loads object parameters from file.

```
virtual bool Load(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] handle of the binary file already opened using the FileOpen(...) function

Return Value

true - successful, false - error.

Type

Returns graphical object type identifier.

```
virtual int Type() const
```

Return Value

Object type identifier (OBJ_GANLINE for [CChartObjectGannLine](#)).

CChartObjectGannFan

CChartObjectGannFan is a class for simplified access to "Gann Fan" graphical object properties.

Description

CChartObjectGannFan class provides access to "Gann Fan" object properties.

Declaration

```

Create

Creates "Gann Fan" graphical object.

```
bool Create(  
    long      chart_id,      // chart identifier  
    string    name,          // object name  
    int       window,        // chart window  
    datetime  time1,         // first time coordinate  
    double    price1,        // first price coordinate  
    datetime  time2,         // second time coordinate  
    double    ppb            // pips per bar  
)
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - base window).

time1

[in] Time coordinate of the first anchor point.

price1

[in] Price coordinate of the first anchor point.

time2

[in] Time coordinate of the second anchor point.

ppb

[in] Pips per bar.

Return Value

true - successful, false - error.

PipsPerBar (Get Method)

Gets the value of "Pips per bar" property.

```
double PipsPerBar() const
```

Return Value

Value of "Pips per bar" property of the object assigned to the class instance. If there is no object assigned, it returns [EMPTY_VALUE](#).

PipsPerBar (Set Method)

Sets new value for "Pips per bar" property.

```
bool PipsPerBar (
    double ppb      // pips per bar
)
```

Parameters

ppb

[in] New value for "Pips per bar" property.

Return Value

true - successful, false - cannot change the property.

Downtrend (Get Method)

Gets the value of "Downtrend" flag.

```
bool Downtrend() const
```

Return Value

Value of the "Downtrend" flag of the object assigned to the class instance. If there is no object assigned, it returns false.

Downtrend (Set Method)

Sets new value of "Downtrend" property.

```
bool Downtrend(  
    bool downtrend    // flag value  
)
```

Parameters

downtrend

[in] New value for "Downtrend" property.

Return Value

true - successful, false - cannot change the flag.

Save

Saves object parameters to file.

```
virtual bool Save(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] handle of the binary file already opened using the FileOpen(...) function.

Return Value

true - successful, false - error.

Load

Loads object parameters from file.

```
virtual bool Load(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] handle of the binary file already opened using the FileOpen(...) function.

Return Value

true - successful, false - error.

Type

Returns graphical object type identifier.

```
virtual int Type() const
```

Return Value

Object type identifier (OBJ_GANNFAN for [CChartObjectGannFan](#)).

CChartObjectGannGrid

CChartObjectGannGrid is a class for simplified access to "Gann Grid" graphical object properties.

Description

CChartObjectGannGrid class provides access to "Gann Grid" object properties.

Declaration

```
class CChartObjectGannGrid : public CChartObjectTrend
```

Title

```
#include <ChartObjects\ChartObjectsGann.mqh>
```

Inheritance hierarchy

[Object types](#), [Graphic objects](#)

Create

Creates "Gann Grid" graphical object.

```
bool Create(  
    long      chart_id,      // chart identifier  
    string     name,         // object name  
    int       window,        // chart window  
    datetime  time1,         // first time coordinate  
    double    price1,        // first price coordinate  
    datetime  time2,         // second time coordinate  
    double    ppb            // pips per bar  
)
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time1

[in] Time coordinate of the first anchor point.

price1

[in] Price coordinate of the first anchor point.

time2

[in] Time coordinate of the second anchor point.

ppb

[in] Pips per bar.

Return Value

true - successful, false - error.

PipsPerBar (Get Method)

Gets the value of "Pips per bar" property.

```
double PipsPerBar() const
```

Return Value

Value of "Pips per bar" property of the object assigned to the class instance. If there is no object assigned, it returns [EMPTY_VALUE](#).

PipsPerBar (Set Method)

Sets new value for "Pips per bar" property.

```
bool PipsPerBar(  
    double ppb      // Pips per bar  
)
```

Parameters

ppb

[in] New value for "Pips per bar" property.

Return Value

true - successful, false - cannot change the property.

Downtrend (Get Method)

Gets the value of "Downtrend" property.

```
bool Downtrend() const
```

Return Value

Value of "Downtrend" property of the object assigned to the class instance. If there is no object assigned, it returns false.

Downtrend (Set Method)

Sets new value of "Downtrend" property.

```
bool Downtrend(  
    bool downtrend    // flag value  
)
```

Parameters

downtrend

[in] New value for "Downtrend" property.

Return Value

true - successful, false - cannot change the property.

Save

Saves object parameters to file.

```
virtual bool Save(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] handle of the binary file already opened using the FileOpen(...) function.

Return Value

true - successful, false - error.

Load

Loads object parameters from file.

```
virtual bool Load(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] handle of the binary file already opened using the FileOpen(...) function.

Return Value

true - successful, false - error.

Type

Returns graphic object type identifier.

```
virtual int Type() const
```

Return Value

Object type identifier (OBJ_GANNGRID for [CChartObjectGannGrid](#)).

Fibonacci Tools

A group of "Fibonacci Tools" graphical objects.

This section contains the technical details of working with a group of classes of "Fibonacci Tools" graphical objects and a description of the relevant components of the MQL5 Standard Library.

Class name	Object
<u>CChartObjectFibo</u>	"Fibonacci Retracement" graphical object
<u>CChartObjectFiboTimes</u>	"Fibonacci Time Zones" graphical object
<u>CChartObjectFiboFan</u>	"Fibonacci Fan" graphical object
<u>CChartObjectFiboArc</u>	"Fibonacci Arc" graphical object
<u>CChartObjectFiboChannel</u>	"Fibonacci Channel" graphical object
<u>CChartObjectFiboExpansion</u>	"Fibonacci Expansion" graphical object

Create

Creates "Fibonacci Retracement" graphical object.

```
bool Create(  
    long      chart_id,    // chart identifier  
    string     name,       // object name  
    int       window,      // chart window  
    datetime  time1,       // first time coordinate  
    double    price1,      // first price coordinate  
    datetime  time2,       // second time coordinate  
    double    price2       // second price coordinate  
)
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time1

[in] Time coordinate of the first anchor point.

price1

[in] Price coordinate of the first anchor point.

time2

[in] Time coordinate of the second anchor point.

price2

[in] Price coordinate of the second anchor point.

Return Value

true - successful, false - error.

Type

Returns graphical object type identifier.

```
virtual int Type() const
```

Return Value

Object type identifier (OBJ_FIBO for [CChartObjectFibo](#)).

CChartObjectFiboTimes

CChartObjectFiboTimes is a class for simplified access to "Fibonacci Time Zones" graphical object properties.

Description

CChartObjectFiboTimes class provides access to "Fibonacci Time Zones" object properties.

Declaration

```
class CChartObjectFiboTimes : public CChartObject
```

Title

```
#include <ChartObjects\ChartObjectsFibo.mqh>
```

Create

Creates "Fibonacci Time Zones" graphical object.

```
bool Create(  
    long      chart_id,      // chart identifier  
    string    name,          // object name  
    int       window,        // chart window  
    datetime  time1,         // first time coordinate  
    double    price1,        // first price coordinate  
    datetime  time2,         // second time coordinate  
    double    price2         // second price coordinate  
)
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time1

[in] Time coordinate of the first anchor point.

price1

[in] Price coordinate of the first anchor point.

time2

[in] Time coordinate of the second anchor point.

price2

[in] Price coordinate of the second anchor point.

Return Value

true - successful, false - error.

Type

Returns graphical object type identifier.

```
virtual int Type() const
```

Return Value

Object type identifier (OBJ_FIBOTIMES for [CChartObjectFiboTimes](#)).

CChartObjectFiboFan

CChartObjectFiboFan is a class for simplified access to "Fibonacci Fan" graphical object properties.

Description

CChartObjectFiboFan class provides access to "Fibonacci Fan" object properties.

Declaration

```
class CChartObjectFiboFan : public CChartObject
```

Title

```
#include <ChartObjects\ChartObjectsFibo.mqh>

[Object types](#), [Graphic objects](#)

Create

Creates "Fibonacci Fan" graphical object.

```
bool Create(  
    long      chart_id,      // chart identifier  
    string    name,          // object name  
    int       window,        // chart window  
    datetime  time1,         // first time coordinate  
    double    price1,        // first price coordinate  
    datetime  time2,         // second time coordinate  
    double    price2         // second price coordinate  
)
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time1

[in] Time coordinate of the first anchor point.

price1

[in] Price coordinate of the first anchor point.

time2

[in] Time coordinate of the second anchor point.

price2

[in] Price coordinate of the second anchor point.

Return Value

true - successful, false - error.

Type

Returns graphical object type identifier.

```
virtual int Type() const
```

Return Value

Object type identifier (OBJ_FIBOFAN for [CChartObjectFiboFan](#)).

CChartObjectFiboArc

CChartObjectFiboArc is a class for simplified access to "Fibonacci Arc" graphical object properties.

Description

CChartObjectFiboArc class provides access to "Fibonacci Arc" object properties.

Declaration

```
class CChartObjectFiboArc : public CChartObject
```

Create

Creates "Fibonacci Arc" graphical object.

```
bool Create(  
    long      chart_id,      // chart identifier  
    string    name,          // object name  
    int       window,        // chart window  
    datetime  time1,         // first time coordinate  
    double    price1,        // first price coordinate  
    datetime  time2,         // second time coordinate  
    double    price2,        // second price coordinate  
    double    scale          // scale  
)
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time1

[in] Time coordinate of the first anchor point.

price1

[in] Price coordinate of the first anchor point.

time2

[in] Time coordinate of the second anchor point.

price2

[in] Price coordinate of the second anchor point.

scale

[in] Scale.

Return Value

true - successful, false - error.

Scale (Get Method)

Gets the value of "Scale" property.

```
double Scale() const
```

Return Value

Value of "Scale" property of the object assigned to the class instance. If there is no object assigned, it returns [EMPTY_VALUE](#).

Scale (Set Method)

Sets new value for "Scale" property.

```
bool Scale(  
    double scale    // scale  
)
```

Parameters

scale

[in] New value for "Scale" property.

Return Value

true - successful, false - cannot change the property.

Ellipse (Get Method)

Gets the value of "Ellipse" flag.

```
bool Ellipse() const
```

Return Value

Value of "Ellipse" flag of the object assigned to the class instance. If there is no object assigned, it returns false.

Ellipse (Set Method)

Sets "Ellipse" flag value.

```
bool Ellipse(  
    bool ellipse    // flag value  
)
```

Parameters

ellipse

[in] New value for "Ellipse" property.

Return Value

true - successful, false - cannot change the property.

Save

Saves object parameters to file.

```
virtual bool Save(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] handle of the binary file already opened using the FileOpen(...) function.

Return Value

true - successful, false - error.

Load

Loads object parameters from file.

```
virtual bool Load(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] handle of the binary file already opened using the FileOpen(...) function.

Return Value

true - successful, false - error.

Type

Returns graphical object type identifier.

```
virtual int Type() const
```

Return Value

Object type identifier (OBJ_FIBOARC for [CChartObjectFiboArc](#)).

CChartObjectFiboChannel

CChartObjectFiboChannel is a class for simplified access to "Fibonacci Channel" graphical object properties.

Description

CChartObjectFiboChannel class provides access to "Fibonacci Channel" object properties.

Declaration

```
class CChartObjectFiboChannel : public CChartObjectTrend
```

Title

```
#include <ChartObjects\ChartObjectsFibo.mqh>

Create

Creates "Fibonacci Channel" graphical object.

```
bool Create(  
    long      chart_id,      // chart identifier  
    string     name,         // object name  
    int       window,        // chart window  
    datetime   time1,        // first time coordinate  
    double     price1,        // first price coordinate  
    datetime   time2,        // second time coordinate  
    double     price2,        // second price coordinate  
    datetime   time3,        // third time coordinate  
    double     price3         // third price coordinate  
)
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time1

[in] Time coordinate of the first anchor point.

price1

[in] Price coordinate of the first anchor point.

time2

[in] Time coordinate of the second anchor point.

price2

[in] Price coordinate of the second anchor point.

time3

[in] Time coordinate of the third anchor point.

price3

[in] Price coordinate of the third anchor point.

Return Value

true - successful, false - error.

Type

Returns graphical object type identifier.

```
virtual int Type() const
```

Return Value

Object type identifier (OBJ_FIBOCHANNEL for [CChartObjectFiboChannel](#)).

CChartObjectFiboExpansion

CChartObjectFiboExpansion is a class for simplified access to "Fibonacci Expansion" graphical object properties.

Description

CChartObjectFiboExpansion class provides access to "Fibonacci Expansion" object properties.

Declaration

    datetime   time1,        // first time coordinate  
    double     price1,        // first price coordinate  
    datetime   time2,        // second time coordinate  
    double     price2,        // second price coordinate  
    datetime   time3,        // third time coordinate  
    double     price3         // third price coordinate  
)
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time1

[in] Time coordinate of the first anchor point.

price1

[in] Price coordinate of the first anchor point.

time2

[in] Time coordinate of the second anchor point.

price2

[in] Price coordinate of the second anchor point.

time3

[in] Time coordinate of the third anchor point.

price3

[in] Price coordinate of the third anchor point.

Return Value

true - successful, false - error.

Type

Returns graphical object type identifier.

```
virtual int Type() const
```

Return Value

Object type identifier (OBJ_EXPANSION for [CChartObjectFiboExpansion](#)).

Create

Creates "Correcting Wave" graphical object.

```
bool Create(  
    long      chart_id,      // chart identifier  
    string    name,          // object name  
    int       window,        // chart window  
    datetime  time1,         // first time coordinate  
    double    price1,        // first price coordinate  
    datetime  time2,         // second time coordinate  
    double    price2,        // second price coordinate  
    datetime  time3,         // third time coordinate  
    double    price3         // third price coordinate  
)
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time1

[in] Time coordinate of the first anchor point.

price1

[in] Price coordinate of the first anchor point.

time2

[in] Time coordinate of the second anchor point.

price2

[in] Price coordinate of the second anchor point.

time3

[in] Time coordinate of the third anchor point.

price3

[in] Time coordinate of the third anchor point.

Return Value

true - successful, false - error.

Degree (Get Method)

Gets the value of "Degree" property.

```
ENUM_ELLIOT_WAVE_DEGREE Degree() const
```

Return Value

Value of "Degree" property of the object assigned to the class instance. If there is no object assigned, it returns WRONG_VALUE.

Degree (Set Method)

Sets new value for "Degree" property.

```
bool Degree(  
    ENUM_ELLIOT_WAVE_DEGREE degree // property value  
)
```

Parameters

degree

[in] New value for "Degree" property.

Return Value

true - successful, false - cannot change the property.

Lines (Get Method)

Gets the value of "Lines" property.

```
bool Lines() const
```

Return Value

Value of "Lines" property of the object assigned to the class instance. If there is no object assigned, it returns false.

Lines (Set Method)

Sets new value for "Lines" property.

```
bool Lines(  
    bool lines    // flag value  
)
```

Parameters

lines

[in] New value for "Lines" property.

Return Value

true - successful, false - cannot change the flag.

Save

Saves object parameters to file.

```
virtual bool Save(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] handle of the binary file already opened using the FileOpen(...) function.

Return Value

true - successful, false - error.

Load

Loads object parameters from file.

```
virtual bool Load(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] handle of the binary file already opened using the FileOpen(...) function.

Return Value

true - successful, false - error.

Type

Returns graphical object type identifier.

```
virtual int Type() const
```

Return Value

Object type identifier (OBJ_ELLIOTWAVE3 for [CChartObjectElliottWave3](#)).

CChartObjectElliottWave5

CChartObjectElliottWave5 is a class for simplified access to "Impulse Wave" graphical object properties.

Description

CChartObjectElliottWave5 class provides access to "Impulse Wave" object properties.

Declaration

```
class CChartObjectElliottWave5 : public CChartObjectElliottWave3
```

Title

```
#include <ChartObjects\ChartObjectsElliott.mqh>
```

Create

Creates "Impulse Wave" graphical object.

```
bool Create(  
    long      chart_id,    // chart identifier  
    string     name,       // object name  
    int       window,      // chart window  
    datetime  time1,       // first time coordinate  
    double    price1,      // first price coordinate  
    datetime  time2,       // second time coordinate  
    double    price2,      // second price coordinate  
    datetime  time3,       // third time coordinate  
    double    price3,      // third price coordinate  
    datetime  time4,       // fourth time coordinate  
    double    price4,      // fourth price coordinate  
    datetime  time5,       // fifth time coordinate  
    double    price5,      // fifth price coordinate  
)
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time1

[in] Time coordinate of the first anchor point.

price1

[in] Price coordinate of the first anchor point.

time2

[in] Time coordinate of the second anchor point.

price2

[in] Price coordinate of the second anchor point.

time3

[in] Time coordinate of the third anchor point.

price3

[in] Price coordinate of the third anchor point.

time4

[in] Time coordinate of the fourth anchor point.

price4

[in] Price coordinate of the fourth anchor point.

time5

[in] Time coordinate of the fifth anchor point.

price5

[in] Price coordinate of the fifth anchor point.

Return Value

true - successful, false - error.

Type

Returns graphical object type identifier.

```
virtual int Type() const
```

Return Value

Object type identifier (OBJ_ELLIOTWAVE5 for [CChartObjectElliottWave5](#)).

Shape Objects

A group of "Shapes" graphical objects.

This section contains the technical details of working with a group of classes of "Shapes" graphical objects and a description of the relevant components of the MQL5 Standard Library.

Class name	Object
<u>CChartObjectRectangle</u>	"Rectangle" graphical objects

Create

Creates "Rectangle" graphical object.

```
bool Create(  
    long      chart_id,      // chart identifier  
    string     name,         // object name  
    long      window,        // chart window  
    datetime   time1,        // first time coordinate  
    double     price1,       // first price coordinate  
    datetime   time2,        // second time coordinate  
    double     price2        // second price coordinate  
)
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time1

[in] Time coordinate of the first anchor point.

price1

[in] Price coordinate of the first anchor point.

time2

[in] Time coordinate of the second anchor point.

price2

[in] Price coordinate of the second anchor point.

Return Value

true - successful, false - error.

Type

Returns graphical object type identifier.

```
int Type() const
```

Return Value

Object type identifier (OBJ_RECTANGLE for [CChartObjectRectangle](#)).

CChartObjectTriangle

CChartObjectTriangle is a class for simplified access to "Triangle" graphical object properties.

Description

CChartObjectTriangle class provides access to "Triangle" object properties.

Declaration

```
class CChartObjectTriangle : public CChartObject
```

Title

```

Create

Creates "Triangle" graphical object.

```
bool Create(  
    long      chart_id,    // chart identifier  
    string     name,       // object name  
    long      window,      // chart window  
    datetime  time1,       // first time coordinate  
    double    price1,      // first price coordinate  
    datetime  time2,       // second time coordinate  
    double    price2,      // second price coordinate  
    datetime  time3,       // third time coordinate  
    double    price3       // third price coordinate  
)
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time1

[in] Time coordinate of the first anchor point.

price1

[in] Price coordinate of the first anchor point.

time2

[in] Time coordinate of the second anchor point.

price2

[in] Price coordinate of the second anchor point.

time3

[in] Time coordinate of the third anchor point.

price3

[in] Price coordinate of the third anchor point.

Return Value

true - successful, false - error.

Type

Returns graphical object type identifier.

```
int Type() const
```

Return Value

Object type identifier (OBJ_TRIANGLE for [CChartObjectTriangle](#)).

CChartObjectEllipse

CChartObjectEllipse is a class for simplified access to "Ellipse" graphical object properties.

Description

CChartObjectEllipse class provides access to "Ellipse" object properties.

Declaration

```
class CChartObjectEllipse : public CChartObject
```

Title

```
#include <ChartObjects\ChartObjectsShapes.mqh>
```

    double    price1,      // first price coordinate  
    datetime  time2,       // second time coordinate  
    double    price2,      // second price coordinate  
    datetime  time3,       // third time coordinate  
    double    price3       // third price coordinate  
)
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time1

[in] Time coordinate of the first anchor point.

price1

[in] Price coordinate of the first anchor point.

time2

[in] Time coordinate of the second anchor point.

price2

[in] Price coordinate of the second anchor point.

time3

[in] Time coordinate of the third anchor point.

price3

[in] Price coordinate of the third anchor point.

Return Value

true - successful, false - error.

Type

Returns graphical object type identifier.

```
int Type() const
```

Return Value

Object type identifier (OBJ_ELLIPSE for [CChartObjectEllipse](#)).

Arrow Objects

Group for Arrows graphical objects.

This section contains the technical details of working with a group of classes of "Arrow" graphical objects and a description of the relevant components of the MQL5 Standard Library. In essence, the arrow is a certain icon which is associated with a specific code. There are two types of "Arrow" graphical object to display icons on the charts:

- "Arrow" object, which allows you to specify the code of the icon displayed by the object.
- Group of objects to display a certain type of icons (corresponding to a certain fixed code).

Class for working with arrows displaying arbitrary code icons

Class name	Name of the arrow object
CChartObjectArrow	Arrow

Classes for working arrows displaying a fixed code icon

Class name	Name of the arrow object
CChartObjectArrowCheck	Check
CChartObjectArrowDown	Arrow Up
CChartObjectArrowUp	Arrow Down
CChartObjectArrowStop	Stop Sign
CChartObjectArrowThumbDown	Thumbs Up
CChartObjectArrowThumbUp	Thumbs Down
CChartObjectArrowLeftPrice	Left Price Label
CChartObjectArrowRightPrice	Right Price Label

See also

[Object types](#), [Methods of Object Binding](#), [Graphic objects](#)

CChartObjectArrow

CChartObjectArrow is a class for simplified access to "Arrow" graphical object properties.

Description

CChartObjectArrow class provides access to common properties of "Arrow" objects to all of its descendants.

Declaration

```
class CChartObjectArrow : public CChartObject
```

Title

```
#include <ChartObjects\ChartObjectsArrows.mqh>
```

Inheritance hierarchy

[CObject](#)

[CChartObject](#)

CChartObjectArrow

Direct descendants

CChartObjectArrowCheck, CChartObjectArrowDown, CChartObjectArrowLeftPrice,
CChartObjectArrowRightPrice, CChartObjectArrowStop, CChartObjectArrowThumbDown,
CChartObjectArrowThumbUp, CChartObjectArrowUp

Class Methods by Groups

Create	
Create	Creates "Arrow" graphical object
Properties	
ArrowCode	Gets/sets "Arrow Code" property
Anchor	Gets/sets "Anchor" property
Input/output	
virtual Save	Virtual method for writing to file
virtual Load	Virtual method for reading from file
virtual Type	Virtual method of identification

Methods inherited from class CObject

See also

[Object types](#), [Methods of objects binding](#), [Graphic objects](#)

Create

Creates "Arrow" graphical object.

```
bool Create(  
    long      chart_id,      // chart ID  
    string     name,         // object Name  
    int       window,        // chart Window  
    datetime   time,         // time  
    double     price,        // price  
    char       code          // arrow code  
)
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique object name.

window

[in] Chart window number (0 - main window).

time

[in] Time coordinate.

price

[in] Price coordinate.

code

[in] "Arrow" code (Wingdings).

Return Value

true - success, false - error.

Example:

```
///--- example for CChartObjectArrow::Create  
#include <ChartObjects\ChartObjectsArrows.mqh>  
///---  
void OnStart()  
{  
    CChartObjectArrow arrow;  
    ///--- set object parameters  
    double price=SymbolInfoDouble(Symbol(),SYMBOL_BID);  
    if(!arrow.Create(0,"Arrow",0,TimeCurrent(),price,181))  
    {  
        ///--- arrow create error  
        printf("Arrow create: Error %d!",GetLastError());  
        ///---  
    }  
}
```

```
        return;  
    }  
    //--- use arrow  
    //--- . . .  
}
```

ArrowCode (Get Method)

Gets "Arrow" symbol code.

```
char ArrowCode() const
```

Return Value

"Arrow" symbol code of the object assigned to the class instance. If there is no object assigned, it returns 0.

ArrowCode (Set Method)

Sets symbol code for "Arrow"

```
bool ArrowCode (
    char code      // code value
)
```

Parameters

code

[in] New value for "arrow" code (Wingdings).

Return Value

true - success, false - cannot change the code.

Example:

```
//--- example for CChartObjectArrow::ArrowCode
#include <ChartObjects\ChartObjectsArrows.mqh>
//---
void OnStart()
{
    CChartObjectArrow arrow;
    char code=181;
    //--- set object parameters
    double price=SymbolInfoDouble(Symbol(),SYMBOL_BID);
    if(!arrow.Create(0,"Arrow",0,TimeCurrent(),price,code))
    {
        //--- arrow create error
        printf("Arrow create: Error %d!",GetLastError());
        //---
        return;
    }
    //--- change the code of arrow
    //--- . . .
    //--- get code of arrow
    if(arrow.ArrowCode()!=code)
    {
        //--- set code of arrow
```

```
        arrow.ArrowCode(code);  
    }  
    //--- use arrow  
    //--- . . .  
}
```

Anchor (Get Method)

Gets anchor type of the "Arrow" object

```
ENUM_ARROW_ANCHOR Anchor() const
```

Return Value

Anchor type of the "Arrow" object assigned to the class instance (to the chart). If there is no object assigned, it returns WRONG_VALUE.

Anchor (Set Method)

Sets anchor type for the "Arrow" object

```
bool Anchor(
    ENUM_ARROW_ANCHOR anchor // anchor type
)
```

Parameters

anchor

[in] New anchor type value

Return Value

true - successful, false - cannot change the anchor type.

Example:

```
//--- example for CChartObject::Anchor
#include <ChartObjects\ChartObjectsArrows.mqh>
//---
void OnStart()
{
    CChartObjectArrow arrow;
    ENUM_ARROW_ANCHOR anchor=ANCHOR_BOTTOM;
    //--- set object parameters
    double price=SymbolInfoDouble(Symbol(),SYMBOL_BID);
    if(!arrow.Create(0,"Arrow",0,TimeCurrent(),price,181))
    {
        //--- arrow create error
        printf("Arrow create: Error %d!",GetLastError());
        //---
        return;
    }
    //--- get anchor of arrow
    if(arrow.Anchor()!=anchor)
    {
        //--- set anchor of arrow
        arrow.Anchor(anchor);
    }
```

```
//--- use arrow  
//--- . . .  
}
```

Save

Saves object parameters to file.

```
virtual bool Save(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] handle of file opened previously using the FileOpen(...) function.

Return Value

true - successful, false - error.

Example:

```
//--- example for CChartObjectArrow::Save  
#include <ChartObjects\ChartObjectsArrows.mqh>  
//---  
void OnStart()  
{  
    int file_handle;  
    CChartObjectArrow arrow;  
    //--- set object parameters  
    double price=SymbolInfoDouble(Symbol(),SYMBOL_BID);  
    if(!arrow.Create(0,"Arrow",0,TimeCurrent(),price,181))  
    {  
        //--- arrow create error  
        printf("Arrow create: Error %d!",GetLastError());  
        //---  
        return;  
    }  
    //--- open file  
    file_handle=FileOpen("MyFile.bin",FILE_WRITE|FILE_BIN|FILE_ANSI);  
    if(file_handle>=0)  
    {  
        if(!arrow.Save(file_handle))  
        {  
            //--- file save error  
            printf("File save: Error %d!",GetLastError());  
            FileClose(file_handle);  
            //---  
            return;  
        }  
        FileClose(file_handle);  
    }  
}
```

Load

Loads object parameters from file.

```
virtual bool Load(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] handle of file previously opened using the FileOpen(...) function.

Return Value

true - success, false - error.

Example:

```
//--- example for CChartObjectArrow::Load  
#include <ChartObjects\ChartObjectsArrows.mqh>  
//---  
void OnStart()  
{  
    int file_handle;  
    CChartObjectArrow arrow;  
    //--- open file  
    file_handle=FileOpen("MyFile.bin",FILE_READ|FILE_BIN|FILE_ANSI);  
    if(file_handle>=0)  
    {  
        if(!arrow.Load(file_handle))  
        {  
            //--- file load error  
            printf("File load: Error %d!",GetLastError());  
            FileClose(file_handle);  
            //---  
            return;  
        }  
        FileClose(file_handle);  
    }  
    //--- use arrow  
    //--- . . .  
}
```

Type

Returns graphical object type identifier.

```
virtual int Type() const
```

Return Value

Object type identifier (for example, OBJ_ARROW for [CChartObjectArrow](#))

Example:

```
//--- example for CChartObjectArrow::Type
#include <ChartObjects\ChartObjectsArrows.mqh>
//---
void OnStart()
{
    CChartObjectArrow arrow;
    //--- get arrow type
    int type=arrow.Type();
}
```

Arrows with fixed code

"Arrows with fixed code" are classes for simplified access to the properties of the following graphical objects:

Class name	Arrow object name
CChartObjectArrowCheck	"Arrow Check"
CChartObjectArrowDown	"Arrow Down"
CChartObjectArrowUp	"Arrow Up"
CChartObjectArrowStop	"Arrow Stop"
CChartObjectArrowThumbDown	"Good" ("Thumbs up")
CChartObjectArrowThumbUp	"Bad" ("Thumbs down")
CChartObjectArrowLeftPrice	"Left price" arrow
CChartObjectArrowRightPrice	"Right price" arrow

Description

"Arrows with fixed code" classes provide access to the object properties.

Declarations

```

class CChartObjectArrowCheck      : public CChartObjectArrow;
class CChartObjectArrowDown      : public CChartObjectArrow;
class CChartObjectArrowUp        : public CChartObjectArrow;
class CChartObjectArrowStop      : public CChartObjectArrow;
class CChartObjectArrowThumbDown : public CChartObjectArrow;
class CChartObjectArrowThumbUp   : public CChartObjectArrow;
class CChartObjectArrowLeftPrice : public CChartObjectArrow;
class CChartObjectArrowRightPrice : public CChartObjectArrow;
```

Title

<ChartObjects\ChartObjectsArrows.mqh>

Class Methods by Groups

Create	
Create	Creates the graphical object matching the class
Properties	
ArrowCode	"Stub" for symbol code change method
Input/output	
virtual Type	Virtual method of identification

See also

[Object types](#), [Methods of object binding](#), [Graphic objects](#)

Create

Creates "Arrow with fixed code" graphical object.

```
bool Create(
    long      chart_id,      // chart ID
    string     name,         // object Name
    int       window,        // chart Window
    datetime   time,         // time
    double     price         // price
)
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] Unique name of the object to create.

window

[in] Chart window number (0 - main window).

time

[in] Time coordinate.

price

[in] Price coordinate.

Return Value

true - successful, false - error.

Example:

```
//--- example for CChartObjectArrowCheck::Create
//--- example for CChartObjectArrowDown::Create
//--- example for CChartObjectArrowUp::Create
//--- example for CChartObjectArrowStop::Create
//--- example for CChartObjectArrowThumbDown::Create
//--- example for CChartObjectArrowThumbUp::Create
//--- example for CChartObjectArrowLeftPrice::Create
//--- example for CChartObjectArrowRightPrice::Create
#include <ChartObjects\ChartObjectsArrows.mqh>
//---
void OnStart()
{
    //--- for example, take CChartObjectArrowCheck
    CChartObjectArrowCheck arrow;
    //--- set object parameters
    double price=SymbolInfoDouble(Symbol(),SYMBOL_BID);
    if(!arrow.Create(0,"ArrowCheck",0,TimeCurrent(),price))
```

```
{
    //--- arrow create error
    printf("Arrow create: Error %d!", GetLastError());
    //---
    return;
}
//--- use arrow
//--- . . .
}
```

ArrowCode

Prohibits "Arrow" symbol code changes.

```
bool ArrowCode(  
    char code    // code value  
)
```

Parameters

code

[in] Any value

Return Value

Always false.

Example:

```
//--- example for CChartObjectArrowCheck::ArrowCode  
//--- example for CChartObjectArrowDown::ArrowCode  
//--- example for CChartObjectArrowUp::ArrowCode  
//--- example for CChartObjectArrowStop::ArrowCode  
//--- example for CChartObjectArrowThumbDown::ArrowCode  
//--- example for CChartObjectArrowThumbUp::ArrowCode  
//--- example for CChartObjectArrowLeftPrice::ArrowCode  
//--- example for CChartObjectArrowRightPrice::ArrowCode  
#include <ChartObjects\ChartObjectsArrows.mqh>  
//---  
void OnStart()  
{  
    //--- for example, take CChartObjectArrowCheck  
    CChartObjectArrowCheck arrow;  
    //--- set object parameters  
    double price=SymbolInfoDouble(Symbol(),SYMBOL_BID);  
    if(!arrow.Create(0,"ArrowCheck",0,TimeCurrent(),price))  
    {  
        //--- arrow create error  
        printf("Arrow create: Error %d!",GetLastError());  
        //---  
        return;  
    }  
    //--- set code of arrow  
    if(!arrow.ArrowCode(181))  
    {  
        //--- it is not error  
        printf("Arrow code can not be changed");  
    }  
    //--- use arrow  
    //--- . . .  
}
```

Type

Returns graphical object type identifier

```
virtual int Type() const
```

Return Value

Object type identifier:

CChartObjectArrowCheck - OBJ_ARROW_CHECK,

CChartObjectArrowDown - OBJ_ARROW_DOWN,

CChartObjectArrowUp - OBJ_ARROW_UP,

CChartObjectArrowStop - OBJ_ARROW_STOP,

CChartObjectArrowThumbDown - OBJ_ARROW_THUMB_DOWN,

CChartObjectArrowThumbUp - OBJ_ARROW_THUMB_UP,

CChartObjectArrowLeftPrice - OBJ_ARROW_LEFT_PRICE,

CChartObjectArrowRightPrice - OBJ_ARROW_RIGHT_PRICE.

Example:

```
//--- example for CChartObjectArrowCheck::Type
//--- example for CChartObjectArrowDown::Type
//--- example for CChartObjectArrowUp::Type
//--- example for CChartObjectArrowStop::Type
//--- example for CChartObjectArrowThumbDown::Type
//--- example for CChartObjectArrowThumbUp::Type
//--- example for CChartObjectArrowLeftPrice::Type
//--- example for CChartObjectArrowRightPrice::Type
#include <ChartObjects\ChartObjectsArrows.mqh>
//---
void OnStart()
{
//--- for example, take CChartObjectArrowCheck
    CChartObjectArrowCheck arrow;
//--- get arrow type
    int type=arrow.Type();
}
```

Control Objects

A group of "Object Controls" graphical objects.

This section contains the technical details of working with a group of classes of "Object Controls" graphical objects and a description of the relevant components of the MQL5 Standard Library.

Class name	Object
<u>CChartObjectText</u>	"Text" graphical object
<u>CChartObjectLabel</u>	"Text Label" graphical object
<u>CChartObjectEdit</u>	"Edit" graphical object
<u>CChartObjectButton</u>	"Button" graphical object
<u>CChartObjectSubChart</u>	"Chart" graphical object
<u>CChartObjectBitmap</u>	"Bitmap" graphical object
<u>CChartObjectBmpLabel</u>	"Bitmap Label" graphical object
<u>CChartObjectRectLabel</u>	"Rectangle Label" graphical object

Create

Creates "Text" graphical object.

```
bool Create(  
    long      chart_id,    // chart identifier  
    string    name,        // object name  
    int       window,      // chart window  
    datetime  time,        // time coordinate  
    double    price        // price coordinate  
)
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time

[in] Time coordinate of the anchor point.

price

[in] Price coordinate of the anchor point.

Return Value

true - successful, false - error.

Angle (Get Method)

Gets the value of "Angle" property.

```
double Angle() const
```

Return Value

Value of "Angle" property of the object assigned to the class instance. If there is no object assigned, it returns EMPTY_VALUE.

Angle (Set Method)

Sets a value for "Angle" property.

```
bool Angle(  
    double angle    // property value  
)
```

Parameters

angle

[in] New value for "Angle" property.

Return Value

true - successful, false - cannot change the property.

Font (Get Method)

Gets the value of "Font" property.

```
string Font() const
```

Return Value

Value of "Font" property of the object assigned to the class instance. If there is no object assigned, it returns "".

Font (Set Method)

Sets new value for "Font" property.

```
bool Font(  
    string font    // property value  
)
```

Parameters

font

[in] New value for "Font" property.

Return Value

true - success, false - cannot change the property.

FontSize (Get Method)

Gets the value of "Font size" property.

```
int FontSize() const
```

Return Value

Value of "FontSize" property of the object assigned to the class instance. If there is no object assigned, it returns 0.

FontSize (Set Method)

Sets new value for "Font size" property.

```
bool FontSize(  
    int size    // property value  
)
```

Parameters

size

[in] New value for "Font size" property.

Return Value

true - successful, false - cannot change the property.

Anchor (Get Method)

Gets the value of "Anchor" property.

```
ENUM_ANCHOR_POINT Anchor() const
```

Return Value

Value of "Anchor" property of the object assigned to the class instance. If there is no object assigned, it returns WRONG_VALUE.

Anchor (Set Method)

Sets new value for "Anchor" property.

```
bool Anchor(  
    ENUM_ANCHOR_POINT anchor    // property value  
)
```

Parameters

anchor

[in] New value for "Anchor" property.

Return Value

true - success, false - cannot change the property.

Save

Saves object parameters to file.

```
virtual bool Save(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] handle of the binary file already opened by the [FileOpen](#) function.

Return Value

true - success, false - error.

Load

Loads object parameters from file.

```
virtual bool Load(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] handle of the binary file already opened by the [FileOpen](#) function.

Return Value

true - successful, false - error.

Type

Returns graphical object type identifier.

```
virtual int Type() const
```

Return Value

Object type identifier (OBJ_TEXT for [CChartObjectText](#)).

CChartObjectLabel

CChartObjectLabel is a class for simplified access to "Label" graphical object properties.

Description

CChartObjectLabel class provides access to "Label" object properties.

Declaration

```
class CChartObjectLabel : public CChartObjectText
```

Title

```
#include <ChartObjects\ChartObjectsTxtControls.mqh>
```

Inheritance hierarchy

Create

Creates "Label" graphical object.

```
bool Create(  
    long    chart_id,    // chart identifier  
    string  name,        // object name  
    int     window,      // chart window  
    int     X,           // X coordinate  
    int     Y            // Y coordinate  
)
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

X

[in] X coordinate.

Y

[in] Y coordinate.

Return Value

true - successful, false - error.

X_Distance (Get Method)

Gets the value of "X_Distance" property.

```
int X_Distance() const
```

Return Value

Value of "X_Distance" property of the object assigned to the class instance. If there is no object assigned, it returns 0.

X_Distance (Set Method)

Sets new value for "X_Distance" property.

```
bool X_Distance(  
    int x      // property value  
)
```

Parameters

x

[in] New value for "X_Distance" property.

Return Value

true - successful, false - cannot change the property.

Y_Distance (Get Method)

Gets the value of "Y_Distance" property.

```
int Y_Distance() const
```

Return Value

Value of "Y_Distance" property of the object assigned to the class instance. If there is no object assigned, it returns 0.

Y_Distance (Set Method)

Sets new value for "Y_Distance" property.

```
bool Y_Distance(  
    int Y    // property value  
)
```

Parameters

Y

[in] New value for "Y_Distance" property.

Return Value

true - successful, false - cannot change the property.

X_Size

Gets the value of "X_Size" property.

```
int X_Size() const
```

Return Value

Value of "X_Size" property of the object assigned to the class instance. If there is no object assigned, it returns 0.

Y_Size

Gets the value of "Y_Size" property.

```
int Y_Size() const
```

Return Value

Value of "Y_Size" property of the object assigned to the class instance. If there is no object assigned, it returns 0.

Corner (Get Method)

Gets the value of "Corner" property.

```
ENUM_BASE_CORNER Corner() const
```

Return Value

Value of "Corner" property of the object assigned to the class instance. If there is no object assigned, it returns WRONG_VALUE.

Corner (Set Method)

Sets new value for "Corner" property.

```
bool Corner(  
    ENUM_BASE_CORNER corner    // property value  
)
```

Parameters

corner

[in] New value for "Corner" property.

Return Value

true - successful, false - cannot change the property.

Time

Prohibits changes of the time coordinate.

```
bool Time(  
    datetime time    // any value  
)
```

Parameters

time

[in] Any value of datetime type.

Return Value

always false.

Price

Prohibits changes of the price coordinate.

```
bool Price(  
    double price    // any value  
)
```

Parameters

price

[in] Any value of double type.

Return Value

always false.

Save

Saves object parameters to file.

```
virtual bool Save(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] handle of the binary file already opened by [FileOpen](#) function.

Return Value

true - successful, false - error.

Load

Loads object parameters from file.

```
virtual bool Load(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] handle of the binary file already opened by [FileOpen](#) function.

Return Value

true - successful, false - error.

Type

Returns graphical object type identifier.

```
virtual int Type() const
```

Return Value

Object type identifier (OBJ_LABEL for [CChartObjectLabel](#)).

CChartObjectEdit

CChartObjectEdit is a class for simplified access to "Edit" graphical object properties.

Description

CChartObjectEdit class provides access to "Edit" object properties.

Declaration

```
class CChartObjectEdit : public CChartObjectLabel
```

Title

```

Create

Creates "Edit" graphical object.

```
bool Create(  
    long    chart_id,    // chart identifier  
    string  name,        // object name  
    int     window,      // chart window  
    int     X,           // X coordinate  
    int     Y,           // Y coordinate  
    int     sizeX,       // X size  
    int     sizeY        // Y size  
)
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

X

[in] X coordinate.

Y

[in] Y coordinate.

sizeX

[in] X size.

sizeY

[in] Y size.

Return Value

true - successful, false - error.

TextAlign (Get method)

Gets the value of "TextAlign" property ([text alignment mode](#)).

```
ENUM_ALIGN_MODE TextAlign() const
```

Return Value

Value of "TextAlign" property of the object assigned to the class instance.

TextAlign (Set method)

Sets the value of "TextAlign" property ([text alignment mode](#)).

```
bool TextAlign(  
    ENUM_ALIGN_MODE align    // property value  
)
```

Parameters

align

[in] New value of "TextAlign" property.

Return Value

true - success, false - cannot change the property.

X_Size

Sets the value for "X_Size" property.

```
bool X_Size(  
    int size    // property value  
)
```

Parameters

size

[in] New value for "X_Size" property.

Return Value

true - success, false - cannot change the property.

Y_Size

Sets the value for "Y_Size" property.

```
bool Y_Size(  
    int size    // property value  
)
```

Parameters

size

[in] New value for "Y_Size" property.

Return Value

true - success, false - cannot change the property.

BackColor (Get Method)

Gets the value of "BackColor" property.

```
color BackColor() const
```

Return Value

Value of "BackColor" property of the object assigned to the class instance. If there is no object assigned, it returns CLR_NONE.

BackColor (Set Method)

Sets the value for "BackColor" property.

```
bool BackColor(  
    color new_color    // property value  
)
```

Parameters

new_color

[in] New value for "BackColor" property.

Return Value

true - success, false - cannot change the property.

BorderColor (Get Method)

Gets the value of "Border Color" property.

```
color BorderColor() const
```

Return Value

Value of "Border Color" property of the object assigned to the class instance. If there is no object assigned, it returns CLR_NONE.

BorderColor (Set Method)

Sets new value for "Border Color" property.

```
bool BorderColor (
    color new_color      // new property value
)
```

Parameters

new_color

[in] New value for "Border Color" property.

Return Value

true - success, false - cannot change the property.

ReadOnly (Get Method)

Gets the value of "Read Only" property.

```
bool ReadOnly() const
```

Return Value

Value of "Read Only" property of the object assigned to the class instance. If there is no object assigned, it returns false.

ReadOnly (Set Method)

Sets the value for "Read Only" property.

```
bool ReadOnly(  
    const bool flag    // new property value  
)
```

Parameters

flag

[in] New value for "Read Only" property (true means text editing is disabled).

Return Value

true - success, false - cannot change the property.

Angle

Prohibits changes of the "Angle" property.

```
bool Angle(  
    double angle    // any value  
)
```

Parameters

angle

[in] Any value of double type.

Return Value

always false.

Save

Saves object parameters to file.

```
virtual bool Save(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] handle of the binary file already opened by [FileOpen](#) function.

Return Value

true - success, false - error.

Load

Loads object parameters from file.

```
virtual bool Load(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] handle of the binary file already opened by [FileOpen](#) function.

Return Value

true - success, false - error.

Type

Returns graphical object type identifier.

```
virtual int Type() const
```

Return Value

Object type identifier (OBJ_EDIT for [CChartObjectEdit](#)).

CChartObjectButton

CChartObjectButton is a class for simplified access to "Button" graphical object properties.

Description

CChartObjectButton class provides access to "Button" object properties.

Declaration

```
class CChartObjectButton : public CChartObjectEdit
```

Title

```
#include <ChartObjects\ChartObjectsTxtControls.mqh>
```

Inheritance hierarchy

State (Get Method)

Gets the value of "State" property.

```
bool State() const
```

Return Value

Value of "State" property of the object assigned to the class instance. If there is no object assigned, it returns false.

State (Set Method)

Sets new value for "State" property.

```
bool State(  
    bool state    // property value  
)
```

Parameters

X

[in] New value for "State" property.

Return Value

true - success, false - cannot change the property.

Save

Saves object parameters to file.

```
virtual bool Save(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] handle of the binary file already opened by [FileOpen](#) function.

Return Value

true - successful, false - error.

Load

Loads object parameters from file.

```
virtual bool Load(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] handle of the binary file already opened by [FileOpen](#) function.

Return Value

true - successful, false - error.

Type

Returns graphical object type identifier.

```
virtual int Type() const
```

Return Value

Object type identifier (OBJ_BUTTON for [CChartObjectButton](#)).

CChartObjectSubChart

CChartObjectSubChart is a class for simplified access to "Chart" graphical object properties.

Description

CChartObjectSubChart class provides access to "Chart" object properties.

Declaration

```
class CChartObjectSubChart : public CChartObject
```

Title

```
#include <ChartObjects\ChartObjectSubChart.mqh>
```

Create

Creates "SubChart" graphical object.

```
bool Create(  
    long    chart_id,    // chart identifier  
    string  name,        // object name  
    int     window,      // chart window  
    int     X,           // X coordinate  
    int     Y,           // Y coordinate  
    int     sizeX,       // X size  
    int     sizeY        // Y size  
)
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

X

[in] X coordinate.

Y

[in] Y coordinate.

sizeX

[in] X size.

sizeY

[in] Y size.

Return Value

true - successful, false - error.

X_Distance (Get Method)

Gets the value of "X_Distance" property.

```
int X_Distance() const
```

Return Value

Value of "X_Distance" property of the object assigned to the class instance. If there is no object assigned, it returns 0.

X_Distance (Set Method)

Sets new value for "X_Distance" property.

```
bool X_Distance(  
    int x    // property value  
)
```

Parameters

x

[in] New value for "X_Distance" property.

Return Value

true - successful, false - cannot change the property.

Y_Distance (Get Method)

Gets the value of "Y_Distance" property.

```
int Y_Distance() const
```

Return Value

Value of "Y_Distance" property of the object assigned to the class instance. If there is no object assigned, it returns 0.

Y_Distance (Set Method)

Sets new value for "Y_Distance" property.

```
bool Y_Distance(  
    int Y      // property value  
)
```

Parameters

Y

[in] New value for "Y_Distance" property.

Return Value

true - successful, false - cannot change the property.

Corner (Get Method)

Gets the value of "Corner" property.

```
ENUM_BASE_CORNER Corner() const
```

Return Value

Value of "Corner" property of the object assigned to the class instance. If there is no object assigned, it returns WRONG_VALUE.

Corner (Set Method)

Sets new value for "Corner" property.

```
bool Corner(  
    ENUM_BASE_CORNER corner    // property value  
)
```

Parameters

corner

[in] New value for "Corner" property.

Return Value

true - successful, false - cannot change the property.

X_Size (Get Method)

Gets the value of "X_Size" property.

```
int X_Size() const
```

Return Value

Value of "X_Size" property of the object assigned to the class instance. If there is no object assigned, it returns 0.

X_Size (Set Method)

Sets new value for "X_Size" property.

```
bool X_Size(  
    int x    // property value  
)
```

Parameters

x

[in] New value for "X_Size" property.

Return Value

true - successful, false - cannot change the property.

Y_Size (Get Method)

Gets the value of "Y_Size" property.

```
int Y_Size() const
```

Return Value

Value of "Y_Size" property of the object assigned to the class instance. If there is no object assigned, it returns 0.

Y_Size (Set Method)

Sets new value for "Y_Size" property.

```
bool Y_Size(  
    int Y    // property value  
)
```

Parameters

Y

[in] New value for "Y_Size" property.

Return Value

true - successful, false - cannot change the property.

Symbol (Get Method)

Gets the value of "Symbol" property.

```
string Symbol() const
```

Return Value

Value of "Symbol" property of the object assigned to the class instance. If there is no object assigned, it returns "".

Symbol (Set Method)

Sets new value for "Symbol" property.

```
bool Symbol(  
    string symbol    // symbol  
)
```

Parameters

symbol

[in] New value for "Symbol" property.

Return Value

true - successful, false - cannot change the property.

Period (Get Method)

Gets the value of "Period" property.

```
int Period() const
```

Return Value

Value of "Period" property of the object assigned to the class instance. If there is no object assigned, it returns 0.

Period (Set Method)

Sets new value for "Period" property.

```
bool Period(  
    int period    // period  
)
```

Parameters

period

[in] New value for "Period" property.

Return Value

true - successful, false - cannot change the property.

Scale (Get Method)

Gets the value of "Scale" property.

```
double Scale() const
```

Return Value

Value of "Scale" property of the object assigned to the class instance. If there is no object assigned, it returns [EMPTY_VALUE](#).

Scale (Set Method)

Sets new value for "Scale" property.

```
bool Scale(  
    double scale    // property value  
)
```

Parameters

scale

[in] New value for "Scale" property.

Return Value

true - successful, false - cannot change the property.

DateScale (Get Method)

Gets the value of "DateScale" flag.

```
bool DateScale() const
```

Return Value

Value of "DateScale" flag of the object assigned to the class instance. If there is no object assigned, it returns false.

DateScale (Set Method)

Sets new value for "DateScale" property.

```
bool DateScale (
    bool scale    // flag value
)
```

Parameters

scale

[in] New value for "DateScale" flag.

Return Value

true - successful, false - cannot change the flag.

PriceScale (Get Method)

Gets the value of "PriceScale" flag.

```
bool PriceScale() const
```

Return Value

Value of "PriceScale" flag of the object assigned to the class instance. If there is no object assigned, it returns false.

PriceScale (Set Method)

Sets new value for "PriceScale" flag.

```
bool PriceScale(  
    bool scale    // flag value  
)
```

Parameters

scale

[in] New value for "PriceScale" flag.

Return Value

true - successful, false - cannot change the flag.

Time

Prohibits changes of the time coordinate.

```
bool Time(  
    datetime time    // any value  
)
```

Parameters

time
[in]

Return Value

always false.

Price

Prohibits changes of the price coordinate.

```
bool Price(  
    double price    // any value  
)
```

Parameters

price
[in]

Return Value

always false.

Save

Saves object parameters to file.

```
virtual bool Save(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] handle of the binary file already opened by [FileOpen](#) function.

Return Value

true - successful, false - error.

Load

Loads object parameters from file.

```
virtual bool Load(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] handle of the binary file already opened by [FileOpen](#) function.

Return Value

true - successful, false - error.

Type

Returns graphical object type identifier.

```
virtual int Type() const
```

Return Value

Object type identifier (OBJ_CHART for [CChartObjectSubChart](#)).

CChartObjectBitmap

CChartObjectBitmap is a class for simplified access to "Bitmap" graphical object properties.

Description

CChartObjectBitmap class provides access to "Bitmap" object properties.

Declaration

```
class CChartObjectBitmap : public CChartObject
```

Title

```
#include <ChartObjects\ChartObjectsBmpControls.mqh>
```

Inheritance hierarchy

Create

Creates "Bitmap" graphical object.

```
bool Create(  
    long      chart_id,    // chart identifier  
    string     name,       // object name  
    int       window,      // chart window  
    datetime   time,       // time coordinate  
    double     price       // price coordinate  
)
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

time

[in] Time coordinate of the anchor point.

price

[in] Price coordinate of the anchor point.

Return Value

true - successful, false - error.

BmpFile (Get Method)

Gets the value of "BmpFile" property.

```
string BmpFile() const
```

Return Value

Value of "BmpFile" property of the object assigned to the class instance. If there is no object assigned, it returns false.

BmpFile (Set Method)

Sets new value for "BmpFile" property.

```
bool BmpFile(  
    string name    // property value  
)
```

Parameters

name

[in] New value for "BmpFile" property.

Return Value

true - successful, false - cannot change the property.

X_Offset (Get Method)

Gets the value of "X_Offset" property (the upper left corner) of the [CChartObjectBitmap](#) graphical object.

```
int X_Offset() const
```

Return Value

Value of "X_Offset" property of the object assigned to the class instance. If there is no object assigned, it returns 0.

X_Offset (Set Method)

Sets new value for "X_Offset" property (the upper left corner) of the [CChartObjectBitmap](#) graphical object. The value is set in pixels relative to the upper left corner of the original image.

```
bool X_Offset(  
    int X        // property value  
)
```

Parameters

X

[in] New value for "X_Offset" property.

Return Value

true - successful, false - cannot change the property.

Y_Offset (Get Method)

Gets the value of "Y_Offset" property (the upper left corner) of the [CChartObjectBitmap](#) graphical object.

```
int Y_Offset() const
```

Return Value

Value of "Y_Offset" property of the object assigned to the class instance. If there is no object assigned, it returns 0.

Y_Offset (Set Method)

Sets new value for "Y_Offset" property (the upper left corner) of the [CChartObjectBitmap](#) graphical object. The value is set in pixels relative to the upper left corner of the original image.

```
bool Y_Offset(  
    int Y      // property value  
)
```

Parameters

Y

[in] New value for "Y_Offset" property.

Return Value

true - successful, false - cannot change the property.

Save

Saves object parameters to file.

```
virtual bool Save(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] handle of the binary file already opened by [FileOpen](#) function.

Return Value

true - successful, false - error.

Load

Loads object parameters from file.

```
virtual bool Load(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] handle of the binary file already opened by [FileOpen](#) function.

Return Value

true - successful, false - error.

Type

Returns graphical object type identifier.

```
virtual int Type() const
```

Return Value

Object type identifier (OBJ_BITMAP for [CChartObjectBitmap](#)).

CChartObjectBmpLabel

CChartObjectBmpLabel is a class for simplified access to "Bitmap Label" graphical object properties.

Description

CChartObjectBmpLabel class provides access to "Bitmap Label" object properties.

Declaration

```
class CChartObjectBmpLabel : public CChartObject
```

Title

```
#include <ChartObjects\ChartObjectsBmpControls.mqh>
```

See also

[Object types](#), [Object properties](#), [Chart angle](#), [Graphic objects](#)

Create

Creates "BmpLabel" graphical object.

```
bool Create(  
    long    chart_id,    // chart identifier  
    string  name,        // object name  
    int     window,      // chart window  
    int     X,           // X coordinate  
    int     Y            // Y coordinate  
)
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

X

[in] X coordinate.

Y

[in] Y coordinate.

Return Value

true - successful, false - error.

X_Distance (Get Method)

Gets the value of "X_Distance" property.

```
int X_Distance() const
```

Return Value

Value of "X_Distance" property of the object assigned to the class instance. If there is no object assigned, it returns 0.

X_Distance (Set Method)

Sets new value for "X_Distance" property.

```
bool X_Distance(  
    int X      // property value  
)
```

Parameters

X

[in] New value for "X_Distance" property.

Return Value

true - successful, false - cannot change the property.

Y_Distance (Get Method)

Gets the value of "Y_Distance" property.

```
int Y_Distance() const
```

Return Value

Value of "Y_Distance" property of the object assigned to the class instance. If there is no object assigned, it returns 0.

Y_Distance (Set Method)

Sets new value for "Y_Distance" property.

```
bool Y_Distance(  
    int Y    // property value  
)
```

Parameters

Y

[in] New value for "Y_Distance" property.

Return Value

true - successful, false - cannot change the property.

X_Offset (Get Method)

Gets the value of "X_Offset" property (the upper left corner) of the [CChartObjectBmpLabel](#) graphical object.

```
int X_Offset() const
```

Return Value

Value of "X_Offset" property of the object assigned to the class instance. If there is no object assigned, it returns 0.

X_Offset (Set Method)

Sets new value for "X_Offset" property (the upper left corner) of the [CChartObjectBitmap](#) graphical object. The value is set in pixels relative to the upper left corner of the original image.

```
bool X_Offset(  
    int X        // property value  
)
```

Parameters

X

[in] New value for "X_Offset" property.

Return Value

true - successful, false - cannot change the property.

Y_Offset (Get Method)

Gets the value of "Y_Offset" property (the upper left corner) of the [CCartObjectBmpLabel](#) graphical object.

```
int Y_Offset () const
```

Return Value

Value of "Y_Offset" property of the object assigned to the class instance. If there is no object assigned, it returns 0.

Y_Offset (Set Method)

Sets new value for "Y_Offset" property (the upper left corner) of the [CCartObjectBmpLabel](#) graphical object. The value is set in pixels relative to the upper left corner of the original image.

```
bool Y_Offset (
    int Y      // property value
)
```

Parameters

Y

[in] New value for "Y_Offset" property.

Return Value

true - successful, false - cannot change the property.

Corner (Get Method)

Gets the value of "Corner" property.

```
ENUM_BASE_CORNER Corner() const
```

Return Value

Value of "Corner" property of the object assigned to the class instance. If there is no object assigned, it returns WRONG_VALUE.

Corner (Set Method)

Sets new value for "Corner" property.

```
bool Corner(  
    ENUM_BASE_CORNER corner    // property value  
)
```

Parameters

corner

[in] New value for "Corner" property.

Return Value

true - successful, false - cannot change the property.

X_Size

Gets the value of "X_Size" property.

```
int X_Size() const
```

Return Value

Value of "X_Size" property of the object assigned to the class instance. If there is no object assigned, it returns 0.

Y_Size

Gets the value of "Y_Size" property.

```
int Y_Size() const
```

Return Value

Value of "Y_Size" property of the object assigned to the class instance. If there is no object assigned, it returns 0.

BmpFileOn (Get Method)

Gets the value of "BmpFileOn" property.

```
string BmpFileOn() const
```

Return Value

Value of "BmpFileOn" property of the object assigned to the class instance. If there is no object assigned, it returns "".

BmpFileOn (Set Method)

Sets new value for "BmpFileOn" property.

```
bool BmpFileOn (
    string name      // file name
)
```

Parameters

name

[in] New value for "BmpFileOn" property.

Return Value

true - successful, false - cannot change the property.

BmpFileOff (Get Method)

Gets the value of "BmpFileOff" property.

```
string BmpFileOff() const
```

Return Value

Value of "BmpFileOff" property of the object assigned to the class instance. If there is no object assigned, it returns "".

BmpFileOff (Set Method)

Sets new value for "BmpFileOff" property.

```
bool BmpFileOff(  
    string name    // file name  
)
```

Parameters

name

[in] New value for "BmpFileOff" property.

Return Value

true - successful, false - cannot change the property.

State (Get Method)

Gets the value of "State" property.

```
bool State() const
```

Return Value

Value of "State" property of the object assigned to the class instance. If there is no object assigned, it returns false.

State (Set Method)

Sets new value for "State" property.

```
bool State(  
    bool state    // property value  
)
```

Parameters

state

[in] New value for "State" property.

Return Value

true - successful, false - cannot change the property.

Time

Prohibits changes of the time coordinate.

```
bool Time(  
    datetime time    // any value  
)
```

Parameters

time

[in] Any value of datetime type.

Return Value

always false.

Price

Prohibits changes of the price coordinate.

```
bool Price(  
    double price    // any value  
)
```

Parameters

price

[in] Any value of double type.

Return Value

always false.

Save

Saves object parameters to file.

```
virtual bool Save(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] handle of the binary file already opened by [FileOpen](#) function.

Return Value

true - successful, false - error.

Load

Loads object parameters from file.

```
virtual bool Load(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] handle of the binary file already opened by [FileOpen](#) function.

Return Value

true - successful, false - error.

Type

Returns graphical object type identifier.

```
virtual int Type() const
```

Return Value

Object type identifier (OBJ_BITMAP_LABEL for [CChartObjectBmpLabel](#)).

CChartObjectRectLabel

CChartObjectRectLabel is a class for simplified access to "Rectangle Label" graphical object properties.

Description

CChartObjectRectLabel class provides access to "Rectangle Label" object properties.

Declaration

```
class CChartObjectRectLabel : public CChartObjectLabel
```

Title

```
#include <ChartObjects\ChartObjectsTxtControls.mqh>
```

Inheritance hierarchy

[CObject](#)

[CChartObject](#)

[CChartObjectText](#)

[CChartObjectLabel](#)

CChartObjectRectLabel

Class Methods by Groups

Create	
Create	Creates "RectLabel" graphical object
Properties	
X_Size	Sets the horizontal size
Y_Size	Sets the vertical size
BackColor	Gets/sets the background color
Angle	Prohibits slope angle change
BorderType	Gets/sets type of the border
Input/output	
virtual Save	Virtual method for writing to file
virtual Load	Virtual method for reading from file
virtual Type	Virtual method of identification

Create

Creates the "CChartObjectRectLabel" graphic object.

```
bool Create(  
    long    chart_id,    // chart ID  
    string  name,        // object name  
    int     window,      // chart window  
    int     X,           // X coordinate  
    int     Y,           // Y coordinate  
    int     sizeX,       // horizontal size  
    int     sizeY        // vertical size  
)
```

Parameters

chart_id

[in] Chart identifier (0 - current chart).

name

[in] A unique name of the object to create.

window

[in] Chart window number (0 - main window).

X

[in] X coordinate.

Y

[in] Y coordinate.

sizeX

[in] Horizontal size.

sizeY

[in] Vertical size.

Return Value

true - successful, false - error.

X_Size

Sets the value of "X_Size" property.

```
bool X_Size(  
    int size    // property value  
)
```

Parameters

size

[in] New horizontal size property value.

Return Value

true - successful, false - cannot change the property.

Note

To get the values of "X_Size" and "Y_Size" properties, use the [X_Size](#) and [Y_Size](#) methods of the parent [CChartObjectLabel](#) class.

Y_Size

Sets the value of "Y_Size" property.

```
bool Y_Size(  
    int size    // property value  
)
```

Parameters

size

[in] New vertical size property value.

Return Value

true - successful, false - cannot change the property.

Note

To get the values of "X_Size" and "Y_Size" properties, use the [X_Size](#) and [Y_Size](#) methods of the parent [CChartObjectLabel](#) class.

BackColor

Gets the background color property value.

```
color BackColor() const
```

Return Value

Background color property value of the object assigned to the class instance. If there is no object assigned, it returns 0.

BackColor

Sets the background color property value.

```
bool BackColor(  
    color new_color    // property value  
)
```

Parameters

new_color

[in] New background color property value.

Return Value

true - successful, false - cannot change the property.

Angle

Prohibits changing the slope angle property.

```
bool Angle(  
    double angle    // any value  
)
```

Parameters

angle

[in] Any value of [double](#) type.

Return Value

Always false.

BorderType

Gets border type property value.

```
int BorderType() const
```

Return Value

Border type property value of the object assigned to the class instance. If there is no object assigned, it returns 0.

BorderType

Sets border type property value.

```
bool BorderType(  
    int type    // property value  
)
```

Parameters

type

[in] New border type property value.

Return Value

true - successful, false - cannot change the property.

Save

Saves object parameters to file.

```
virtual bool Save(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] handle of the binary file already opened by [FileOpen](#) function.

Return Value

true - successful, false - error.

Load

Loads object parameters from file.

```
virtual bool Load(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] handle of the binary file already opened by [FileOpen](#) function.

Return Value

true - successful, false - error.

Type

Returns graphical object type identifier.

```
virtual int Type() const
```

Return Value

Object type identifier (OBJ_RECTANGLE_LABEL for [CChartObjectRectangleLabel](#)).

CCanvas

CCanvas is a class for simplified creation of custom images.

Description

CCanvas provides creation of a graphical resource (with or without binding to a chart object) and drawing graphic primitives.

Declaration

```
class CCanvas
```

Title

```
#include <Canvas\Canvas.mqh>
```

Inheritance hierarchy

CCanvas

Direct descendants

CChartCanvas, CFlameCanvas

Class methods by groups

Creating	
Attach	Attaches the OBJ_BITMAP_LABEL object to an instance of the CCanvas class
Create	Creates a graphical resource without binding to a chart object
CreateBitmap	Create a graphical resource bound to a chart object
CreateBitmapLabel	Create a graphical resource bound to a chart object
Destroy	Destroys a graphical resource
Properties	
ChartObjectName	Gets the name of a bound chart object
ResourceName	Gets the name of a graphical resource
Width	Gets the width of a graphical resource
Height	Gets the height of a graphical resource
LineStyleSet	Sets the line style
Updates an object on the screen	

Update	Displays changes on the screen
Resize	Resizes a graphical resource
Erasing/Filling with color	
Erase	Erases or fills with the specified color
Data access	
PixelGet	Gets a color of the dot with the specified coordinates
PixelSet	Sets color of the dot with the specified coordinates
Draws primitives	
LineVertical	Draws a vertical line
LineHorizontal	Draws a horizontal line
Line	Draws a freehand line
Polyline	Draws a polyline
Polygon	Draws a polygon
Rectangle	Draws a rectangle
Circle	Draws a circle
Triangle	Draws a triangle
Ellipse	Draws an ellipse
Arc	Draws an ellipse arc
Pie	Draws an ellipse sector
Draws filled primitives	
FillRectangle	Draws a filled rectangle
FillCircle	Draws a filled circle
FillTriangle	Draws a filled triangle
FillPolygon	Draws a filled polygon
FillEllipse	Draws a filled ellipse
Fill	Fills an area
Draws primitives with antialiasing	
PixelSetAA	Draws a pixel
LineAA	Draws a line
PolylineAA	Draws a polyline

<u>PolygonAA</u>	Draws a polygon
<u>TriangleAA</u>	Draws a triangle
<u>CircleAA</u>	Draws a circle
<u>EllipseAA</u>	Draws an ellipse
<u>LineWu</u>	Draws a line
<u>PolylineWu</u>	Draws a polyline
<u>PolygonWu</u>	Draws a polygon
<u>TriangleWu</u>	Draws a triangle
<u>CircleWu</u>	Draws a circle
<u>EllipseWu</u>	Draws an ellipse
<u>LineThick</u>	Draws a segment of a freehand line having a specified width using antialiasing algorithm.
<u>LineThickVertical</u>	Draws a vertical segment of a freehand line having a specified width using antialiasing algorithm.
<u>LineThickHorizontal</u>	Draws a horizontal segment of a freehand line having a specified width using antialiasing algorithm.
<u>PolygonSmooth</u>	Draws a polygon with a specified width using two antialiasing algorithms
<u>PolygonThick</u>	Draws a polygon with a specified width using antialiasing algorithm
<u>PolylineSmooth</u>	Draws a polyline with a specified width using two antialiasing algorithms
<u>PolylineThick</u>	Draws a polyline with a specified width using antialiasing algorithm
Text	
<u>FontSet</u>	Sets font parameters
<u>FontNameSet</u>	Sets font name
<u>FontSizeSet</u>	Sets font size
<u>FontFlagsSet</u>	Sets font flags
<u>FontAngleSet</u>	Sets font slope angle
<u>FontGet</u>	Gets font parameters
<u>FontNameGet</u>	Gets font name
<u>FontSizeGet</u>	Gets font size

<u>FontFlagsGet</u>	Gets font flags
<u>FontAngleGet</u>	Gets font slope angle
<u>TextOut</u>	Displays text
<u>TextWidth</u>	Gets the text width
<u>TextHeight</u>	Gets the text height
<u>TextSize</u>	Gets the text size
Transparency	
<u>TransparentLevelSet</u>	Sets transparency level
Input/output	
<u>LoadFromFile</u>	Reads an image from a BMP file

Attach

Gets the graphical resource from an [OBJ_BITMAP_LABEL](#) object and attaches it to an instance of the CCanvas class.

```
bool Attach(  
    const long      chart_id,           // chart identifier  
    const string    objname,           // object name  
    ENUM_COLOR_FORMAT clrfmt=COLOR_FORMAT_XRGB_NOALPHA // color processing method  
    e.)
```

Creates a graphical [resource](#) for an [OBJ_BITMAP_LABEL](#) object and attaches it to an instance of the CCanvas class.

```
bool Attach(  
    const long      chart_id,           // chart identifier  
    const string    objname,           // object name  
    const int       width,             // image width in pixels  
    const int       height,            // image height in pixels  
    ENUM_COLOR_FORMAT clrfmt=COLOR_FORMAT_XRGB_NOALPHA // color processing method  
    e.)
```

Parameters

chart_id

[out] Chart identifier.

objname

[in] Name of the graphical object.

width

[in] Image width in the resource.

height

[in] Image height in the resource.

clrfmt=COLOR_FORMAT_XRGB_NOALPHA

[in] Alpha channel processing method. The alpha channel is ignored by default.

Return Value

true - if successful, false - if failed to attach the object.

Arc

Draws an arc of an ellipse inscribed in a rectangle with corners at (x1,y1) and (x2,y2). The arc boundaries are clipped by lines from the center of the ellipse, which extend to two points with coordinates (x3,y3) and (x4,y4).

```
void Arc(  
    int      x1,      // X coordinate of the upper left corner of the rectangle  
    int      y1,      // Y coordinate of the upper left corner of the rectangle  
    int      x2,      // X coordinate of the bottom right corner of the rectangle  
    int      y2,      // Y coordinate of the bottom right corner of the rectangle  
    int      x3,      // X coordinate of the first point to find the arc boundaries  
    int      y3,      // Y coordinate of the first point to find the arc boundaries  
    int      x4,      // X coordinate of the second point to find the arc boundaries  
    int      y4,      // Y coordinate of the second point to find the arc boundaries  
    const uint clr     // color  
);
```

Parameters

x1

[in] X coordinate of the top left corner forming the rectangle.

y1

[in] Y coordinate of the top left corner forming the rectangle.

x2

[in] X coordinate of the bottom right corner forming the rectangle.

y2

[in] Y coordinate of the bottom right corner forming the rectangle.

x3

[in] X coordinate of the first point, to which a line from the rectangle center is drawn in order to obtain the arc boundary.

y3

[in] Y coordinate of the first point, to which a line from the rectangle center is drawn in order to obtain the arc boundary.

x4

[in] X coordinate of the second point, to which a line from the rectangle center is drawn in order to obtain the arc boundary.

y4

[in] Y coordinate of the second point, to which a line from the rectangle center is drawn in order to obtain the arc boundary.

clr

[in] Color in ARGB format. Use the [ColorToARGB\(\)](#) function to convert a color into the ARGB format.

Draws an arc of an ellipse with center at point (x,y), inscribed in rectangle, with radii rx and ry. The arc boundaries are cropped from the ellipse center using rays formed by angles fi3 and fi4.

```
void Arc(
    int      x,          // X coordinate of the ellipse center
    int      y,          // Y coordinate of the ellipse center
    int      rx,         // ellipse radius on the X axis
    int      ry,         // ellipse radius on the Y axis
    int      fi3,        // angle of ray from ellipse center, which defines the first boundary
    int      fi4,        // angle of ray from ellipse center, which defines the second boundary
    const uint clr       // color
);
```

Draws an arc of an ellipse with center at point (x,y), inscribed in rectangle, with radii rx and ry, and also returns the coordinates of the arc boundaries. The arc boundaries are cropped from the ellipse center using rays formed by angles fi3 and fi4.

```
void Arc(
    int      x,          // X coordinate of the ellipse center
    int      y,          // Y coordinate of the ellipse center
    int      rx,         // ellipse radius on the X axis
    int      ry,         // ellipse radius on the Y axis
    int      fi3,        // angle of ray from ellipse center, which defines the first boundary
    int      fi4,        // angle of ray from ellipse center, which defines the second boundary
    int&     x3,         // X coordinate of the first arc boundary
    int&     y3,         // Y coordinate of the first arc boundary
    int&     x4,         // X coordinate of the second arc boundary
    int&     y4,         // Y coordinate of the second arc boundary
    const uint clr       // color
);
```

Parameters

x

[in] X coordinate of the ellipse center.

y

[in] Y coordinate of the ellipse center.

rx

[in] Ellipse radius on the X axis, in pixels.

ry

[in] Ellipse radius on the Y axis, in pixels.

fi3

[in] Angle in radians, which defines the first boundary of the arc.

fi4

[in] Angle in radians, which defines the second boundary of the arc.

x3

[out] Variable to get the X coordinate of the first arc boundary.

y3

[out] Variable to get the Y coordinate of the first arc boundary.

x4

[out] Variable to get the X coordinate of the second arc boundary.

y4

[out] Variable to get the Y coordinate of the second arc boundary.

clr

[in] Color in ARGB format. Use the [ColorToARGB\(\)](#) function to convert a color into the ARGB format.

Examples of calling the class methods:

```
#include <Canvas\Canvas.mqh>
CCanvas canvas;

//+-----+
//| Script program start function |
//+-----+

void OnStart()
{
    int      Width=600;
    int      Height=400;
    //--- create canvas
    if(!canvas.CreateBitmapLabel(0,0,"CirclesCanvas",30,30,Width,Height))
    {
        Print("Error creating canvas: ",GetLastError());
    }
    //--- clear canvas
    canvas.Erase clrWhite);
    //--- draw rectangle
    canvas.Rectangle(215-190,215-120,215+190,215+120,clrGray);
    //--- draw first arc
    canvas.Arc(215,215, 190,120,M_PI_4,2*M_PI-M_PI_4,ColorToARGB(clrRed));
    int x1,y1,x2,y2;
    //--- draw second arc
    canvas.Arc(215,215, 190,120,2*M_PI-M_PI_4,2*M_PI+M_PI_4,x1,y1,x2,y2,ColorToARGB(clrBlue));
    //--- print coordinates of arc
    PrintFormat("First point of arc at (%G,%G), second point of arc at (%G,%G)",x1,y1,x2,y2);
    canvas.CircleAA(x1,y1,3, ColorToARGB(clrRed));
    canvas.CircleAA(x2,y2,3, ColorToARGB(clrBlue));
    //--- show updated canvas
    canvas.Update();
}
```

Pie

Draws a filled sector of an ellipse inscribed in a rectangle with corners at (x1,y1) and (x2,y2). The sector boundaries are clipped by lines from the center of the ellipse, which extend to two points with coordinates (x3,y3) and (x4,y4).

```
void Pie(
    int      x1,        // X coordinate of the upper left corner of the rectangle
    int      y1,        // Y coordinate of the upper left corner of the rectangle
    int      x2,        // X coordinate of the bottom right corner of the rectangle
    int      y2,        // Y coordinate of the bottom right corner of the rectangle
    int      x3,        // X coordinate of the first point to find the arc boundaries
    int      y3,        // Y coordinate of the first point to find the arc boundaries
    int      x4,        // X coordinate of the second point to find the arc boundaries
    int      y4,        // Y coordinate of the second point to find the arc boundaries
    const uint clr,     // line color
    const uint fill_clr // fill color
);
```

Parameters

x1

[in] X coordinate of the top left corner forming the rectangle.

y1

[in] Y coordinate of the top left corner forming the rectangle.

x2

[in] X coordinate of the bottom right corner forming the rectangle.

y2

[in] Y coordinate of the bottom right corner forming the rectangle.

x3

[in] X coordinate of the first point, to which a line from the rectangle center is drawn in order to obtain the arc boundary.

y3

[in] Y coordinate of the first point, to which a line from the rectangle center is drawn in order to obtain the arc boundary.

x4

[in] X coordinate of the second point, to which a line from the rectangle center is drawn in order to obtain the arc boundary.

y4

[in] Y coordinate of the second point, to which a line from the rectangle center is drawn in order to obtain the arc boundary.

clr

[in] Border color of the sector in the ARGB format.

fill_clr

[in] Fill color of the sector in the ARGB format. Use the [ColorToARGB\(\)](#) function to convert a color into the ARGB format.

Draws a filled sector of an ellipse with center at point (x,y), inscribed in rectangle, with radii rx and ry. The sector boundaries are cropped from the ellipse center by rays formed by angles fi3 and fi4.

```
void Pie(
    int      x,          // X coordinate of the ellipse center
    int      y,          // Y coordinate of the ellipse center
    int      rx,         // ellipse radius on the X axis
    int      ry,         // ellipse radius on the Y axis
    int      fi3,        // angle of ray from ellipse center, which defines the first boundary
    int      fi4,        // angle of ray from ellipse center, which defines the second boundary
    const uint clr,      // line color
    const uint fill_clr // fill color
);
```

Draws a filled sector of an ellipse with center at point (x,y), inscribed in rectangle, with radii rx and ry, and also returns the coordinates of the arc boundaries. The sector boundaries are cropped from the ellipse center by rays formed by angles fi3 and fi4.

```
void Pie(
    int      x,          // X coordinate of the ellipse center
    int      y,          // Y coordinate of the ellipse center
    int      rx,         // ellipse radius on the X axis
    int      ry,         // ellipse radius on the Y axis
    int      fi3,        // angle of ray from ellipse center, which defines the first boundary
    int      fi4,        // angle of ray from ellipse center, which defines the second boundary
    int&     x3,         // X coordinate of the first arc boundary
    int&     y3,         // Y coordinate of the first arc boundary
    int&     x4,         // X coordinate of the second arc boundary
    int&     y4,         // Y coordinate of the second arc boundary
    const uint clr,      // line color
    const uint fill_clr // fill color
);
```

Parameters

x

[in] X coordinate of the ellipse center.

y

[in] Y coordinate of the ellipse center.

rx

[in] Ellipse radius on the X axis, in pixels.

ry

[in] Ellipse radius on the Y axis, in pixels.

fi3

[in] Angle in radians, which defines the first boundary of the arc.

fi4

[in] Angle in radians, which defines the second boundary of the arc.

x3

[out] Variable to get the X coordinate of the first arc boundary.

y3

[out] Variable to get the Y coordinate of the first arc boundary.

x4

[out] Variable to get the X coordinate of the second arc boundary.

y4

[out] Variable to get the Y coordinate of the second arc boundary.

clr

[in] Border color of the sector in the ARGB format.

fill_clr[in] Fill color of the sector in the ARGB format. Use the [ColorToARGB\(\)](#) function to convert a color into the ARGB format.

Examples of calling the class methods:

```
#include <Canvas\Canvas.mqh>
CCanvas canvas;
//+-----+
//| Script program start function |
//+-----+
void OnStart()
{
    int      Width=600;
    int      Height=400;
//--- create canvas
    if(!canvas.CreateBitmapLabel(0,0,"CirclesCanvas",30,30,Width,Height))
    {
        Print("Error creating canvas: ",GetLastError());
    }
//--- clear canvas
    canvas.Erase clrWhite);
//--- draw rectangle
    canvas.Rectangle(215-190,215-120,215+190,215+120,clrGray);
//--- draw first pie
    canvas.Pie(215,215, 190,120,M_PI_4,2*M_PI-M_PI_4,ColorToARGB(clrBlue),ColorToARGB(c
//--- draw second pie
    canvas.Pie(215,215, 190,120,2*M_PI-M_PI_4,2*M_PI+M_PI_4,ColorToARGB(clrGreen),Color
//--- show updated canvas
    canvas.Update();
```

```
DebugBreak();  
}
```

FillPolygon

Draws a filled polygon.

```
void FillPolygon(  
    int&      x,      // array with the X coordinates of polygon points  
    int&      y,      // array with the Y coordinates of polygon points  
    const uint clr    // color  
);
```

Parameters

x

[in] Array of the X coordinates of the polygon points.

y

[in] Array of the Y coordinates of the polygon points.

clr

[in] Color in ARGB format.

FillEllipse

Draws a filled ellipse inscribed in a rectangle with the specified coordinates.

```
void FillPolygon(  
    int      x1,      // X coordinate of the upper left corner of the rectangle  
    int      y1,      // Y coordinate of the upper left corner of the rectangle  
    int      x2,      // X coordinate of the bottom right corner of the rectangle  
    int      y2,      // Y coordinate of the bottom right corner of the rectangle  
    const uint clr     // ellipse color  
);
```

Parameters

x1

[in] X coordinate of the top left corner forming the rectangle.

y1

[in] Y coordinate of the top left corner forming the rectangle.

x2

[in] X coordinate of the bottom right corner forming the rectangle.

y2

[in] Y coordinate of the bottom right corner forming the rectangle.

clr

[in] Color in ARGB format.

GetDefaultColor

Returns a predefined color by its index.

```
static uint GetDefaultColor(  
    const uint i      // index  
);
```

Parameters

i

[in] Index to get the color.

Return Value

Color.

ChartObjectName

Receives the name of a bound chart object.

```
string ChartObjectName();
```

Return Value

the name of a bound chart object

Circle

Draws a circle

```
void Circle(  
    int      x,      // X coordinate  
    int      y,      // Y coordinate  
    int      r,      // radius  
    const uint clr    // color  
);
```

Parameters

x

[in] X coordinate of the center of the circle.

y

[in] Y coordinate of the center of the circle.

r

[in] Circle radius.

clr

[in] Color in ARGB format.

CircleAA

Draws a circle using antialiasing algorithm

```
void CircleAA(  
    const int    x,        // X coordinate  
    const int    y,        // Y coordinate  
    const double r,        // radius  
    const uint   clr       // color  
) ;
```

Parameters

x

[in] X coordinate of the center of the circle.

y

[in] Y coordinate of the center of the circle.

r

[in] Circle radius.

clr

[in] Color in ARGB format.

Create

Creates a graphical resource without binding to a chart object.

```
virtual bool Create(  
    const string      name,                // name  
    const int         width,              // width  
    const int         height,            // height  
    ENUM_COLOR_FORMAT clrfmt=COLOR_FORMAT_XRGB_NOALPHA // format  
);
```

Parameters

name

[in] Basis for a graphical resource name. A resource name is generated during the creation by adding a pseudorandom string.

width

[in] Width (size along X axis) in pixels.

height

[in] Height (size along Y axis) in pixels.

clrfmt=COLOR_FORMAT_XRGB_NOALPHA

[in] Color processing method. See [ResourceCreate\(\)](#) function description to learn more about color processing methods.

Return Value

true - successful, otherwise - false

CircleWu

Draws a circle using Wu's anti-aliasing algorithm

```
void CircleWu(  
    const int    x,        // X coordinate  
    const int    y,        // Y coordinate  
    const double r,        // radius  
    const uint   clr       // color  
) ;
```

Parameters

x

[in] X coordinate of the center of the circle.

y

[in] Y coordinate of the center of the circle.

r

[in] Circle radius.

clr

[in] Color in ARGB format.

CreateBitmap

Creates a graphical resource bound to a chart object.

1. Creates a graphical resource in the main window of the current chart.

```
bool CreateBitmap(
    const string      name,           // name
    const datetime    time,           // time
    const double      price,          // price
    const int         width,          // width
    const int         height,         // height
    ENUM_COLOR_FORMAT clrfmt=COLOR_FORMAT_XRGB_NOALPHA // format
);
```

2. Creates a graphical resource using a chart ID and a subwindow number.

```
bool CreateBitmap(
    const long        chart_id,       // chart ID
    const int         subwin,         // subwindow number
    const string      name,           // name
    const datetime    time,           // time
    const double      price,          // price
    const int         width,          // width
    const int         height,         // height
    ENUM_COLOR_FORMAT clrfmt=COLOR_FORMAT_XRGB_NOALPHA // format
);
```

Parameters

chart_id

[in] Chart ID for creating an object.

subwin

[in] Chart subwindow number for creating an object.

name

[in] Chart object name and a basis for a graphical resource name.

time

[in] Chart object anchor point time coordinate.

price

[in] Chart object anchor point price coordinate.

width

[in] Graphical resource width (size along X axis) in pixels.

height

[in] Graphical resource height (size along Y axis) in pixels.

clrfmt=COLOR_FORMAT_XRGB_NOALPHA

[in] Color processing method. See [ResourceCreate\(\)](#) function description to learn more about color processing methods.

Return Value

true - successful, otherwise - false

Note

If the first function version is used, the object is created in the main window of the current chart.

Object size coincides with the size of a graphical resource.

CreateBitmapLabel

Creates a graphical resource bound to a chart object.

1. Creates a graphical resource in the main window of the current chart.

```
bool CreateBitmapLabel(
    const string      name,                // name
    const int         x,                  // X coordinate
    const int         y,                  // Y coordinate
    const int         width,              // width
    const int         height,             // height
    ENUM_COLOR_FORMAT clrfmt=COLOR_FORMAT_XRGB_NOALPHA // format
);
```

2. Creates a graphical resource using a chart ID and a subwindow number.

```
bool CreateBitmapLabel(
    const long        chart_id,           // chart ID
    const int         subwin,            // subwindow number
    const string      name,              // name
    const int         x,                  // X coordinate
    const int         y,                  // Y coordinate
    const int         width,             // width
    const int         height,            // height
    ENUM_COLOR_FORMAT clrfmt=COLOR_FORMAT_XRGB_NOALPHA // format
);
```

Parameters

chart_id

[in] Chart ID for creating an object.

subwin

[in] Chart subwindow number for creating an object.

name

[in] Chart object name and a basis for a graphical resource name.

x

[in] Chart object anchor point X coordinate.

y

[in] Chart object anchor point Y coordinate.

width

[in] Graphical resource width (size along X axis) in pixels.

height

[in] Graphical resource height (size along Y axis) in pixels.

clrfmt=COLOR_FORMAT_XRGB_NOALPHA

[in] Color processing method. See [ResourceCreate\(\)](#) function description to learn more about color processing methods.

Return Value

true - successful, otherwise - false

Note

If the first function version is used, the object is created in the main window of the current chart.

Object size coincides with the size of a graphical resource.

Destroy

Destroys a graphical resource.

```
void Destroy();
```

Note

If a graphical resource has been bound to a chart object, the latter is deleted.

Ellipse

Draws an ellipse using two points.

```
void Ellipse(  
    int      x1,      // X coordinate  
    int      y1,      // Y coordinate  
    int      x2,      // X coordinate  
    int      y2,      // Y coordinate  
    const uint clr     // color  
);
```

Parameters

x1

[in] X coordinate of the first point forming an ellipse.

y1

[in] Y coordinate of the first point forming an ellipse.

x2

[in] X coordinate of the second point forming an ellipse.

y2

[in] Y coordinate of the second point forming an ellipse.

clr

[in] Color in ARGB format.

Erase

Erases or fills with the specified color.

```
void Erase(  
    const uint clr=0    // color  
);
```

Parameters

clr=0

[in] Color in ARGB format.

EllipseAA

Draws an ellipse based on two points using anti-aliasing algorithm.

```
void EllipseAA(  
    int      x1,      // X coordinate  
    int      y1,      // Y coordinate  
    int      x2,      // X coordinate  
    int      y2,      // Y coordinate  
    const uint clr     // color  
);
```

Parameters

x1

[in] X coordinate of the first point forming an ellipse.

y1

[in] Y coordinate of the first point forming an ellipse.

x2

[in] X coordinate of the second point forming an ellipse.

y2

[in] Y coordinate of the second point forming an ellipse.

clr

[in] Color in ARGB format.

EllipseWu

Draws an ellipse based on two points using Wu's anti-aliasing algorithm.

```
void EllipseWu(  
    int      x1,      // X coordinate  
    int      y1,      // Y coordinate  
    int      x2,      // X coordinate  
    int      y2,      // Y coordinate  
    const uint clr     // color  
);
```

Parameters

x1

[in] X coordinate of the first point forming an ellipse.

y1

[in] Y coordinate of the first point forming an ellipse.

x2

[in] X coordinate of the second point forming an ellipse.

y2

[in] Y coordinate of the second point forming an ellipse.

clr

[in] Color in ARGB format.

Fill

Fills an area.

```
void Fill(  
    int      x,          // X coordinate  
    int      y,          // Y coordinate  
    const uint clr       // color  
);
```

Parameters

x

[in] X coordinate of filling starting point.

y

[in] Y coordinate of filling starting point.

clr

[in] Color in ARGB format.

FillCircle

Draws a filled circle.

```
void FillCircle(  
    int      x,          // X coordinate  
    int      y,          // Y coordinate  
    int      r,          // radius  
    const uint clr       // color  
);
```

Parameters

x

[in] X coordinate of a filled circle center.

y

[in] Y coordinate of a filled circle center.

r

[in] Filled circle radius.

clr

[in] Color in ARGB format.

FillRectangle

Draws a filled rectangle.

```
void FillRectangle(  
    int      x1,      // X coordinate  
    int      y1,      // Y coordinate  
    int      x2,      // X coordinate  
    int      y2,      // Y coordinate  
    const uint clr     // color  
);
```

Parameters

x1

[in] X coordinate of the first point forming a rectangle.

y1

[in] Y coordinate of the first point forming a rectangle.

x2

[in] X coordinate of the second point forming a rectangle.

y2

[in] Y coordinate of the second point forming a rectangle.

clr

[in] Color in ARGB format.

FillTriangle

Draws a filled triangle.

```
void FillTriangle(  
    int      x1,      // X coordinate  
    int      y1,      // Y coordinate  
    int      x2,      // X coordinate  
    int      y2,      // Y coordinate  
    int      x3,      // X coordinate  
    int      y3,      // Y coordinate  
    const uint clr     // color  
);
```

Parameters

x1

[in] X coordinate of the triangle's first corner.

y1

[in] Y coordinate of the triangle's first corner.

x2

[in] X coordinate of the triangle's second corner.

y2

[in] Y coordinate of the triangle's second corner.

x3

[in] X coordinate of the triangle's third corner.

y3

[in] Y coordinate of the triangle's third corner.

clr

[in] Color in ARGB format.

FontAngleGet

Receives font slope angle.

```
uint FontAngleGet ();
```

Return Value

font slope angle

FontAngleSet

Sets font slope angle.

```
bool FontAngleSet(  
    uint angle    // angle  
);
```

Parameters

angle

[in] Font slope angle in tenths of a degree.

Return Value

true - successful, otherwise - false

FontFlagsGet

Receives font flags.

```
uint FontFlagsGet ();
```

Return Value

font flags

FontFlagsSet

Sets font flags.

```
bool FontFlagsSet(  
    uint flags    // flags  
);
```

Parameters

flags

[in] Font creation flags. See [TextSetFont\(\)](#) function description to learn more about the flags.

Return Value

true - successful, otherwise - false

FontGet

Receives the current font parameters.

```
void FontGet(  
    string& name,      // name  
    int& size,         // size  
    uint& flags,       // flags  
    uint& angle        // slope angle  
);
```

Parameters

name

[out] Reference to the variable for returning a font name.

size

[out] Reference to the variable for returning a font size.

flags

[out] Reference to the variable for returning font flags.

angle

[out] Reference to the variable for returning a font slope angle.

FontNameGet

Receives font name.

```
string FontNameGet();
```

Return Value

font name

FontNameSet

Sets font name.

```
bool FontNameSet(  
    string name    // name  
);
```

Parameters

name

[in] Font name. For example, "Arial".

Return Value

true - successful, otherwise - false

FontSet

Sets the current font.

```
bool FontSet(  
    const string name,           // name  
    const int size,             // size  
    const uint flags=0,         // flags  
    const uint angle=0          // angle  
);
```

Parameters

name

[in] Font name. For example, "Arial".

size

[in] Font size. See [TextSetFont\(\)](#) function description to learn more about setting a size.

flags=0

[in] Font creation flags. See [TextSetFont\(\)](#) function description to learn more about the flags.

angle=0

[in] Font slope angle in tenths of a degree.

Return Value

true - successful, otherwise - false

FontSizeGet

Receives font size.

```
int FontSizeGet();
```

Return Value

font size

FontSizeSet

Sets font size.

```
bool FontSizeSet(  
    int size    // size  
);
```

Parameters

size

[in] Font size. See [TextSetFont\(\)](#) function description to learn more about setting a size.

Return Value

true - successful, otherwise - false

Height

Receives the height of a graphical resource.

```
int Height();
```

Return Value

height of a graphical resource

Line

Draws a segment of a freehand line.

```
void Line(  
    int      x1,      // X coordinate  
    int      y1,      // Y coordinate  
    int      x2,      // X coordinate  
    int      y2,      // Y coordinate  
    const uint clr     // color  
);
```

Parameters

x1

[in] X coordinate of the segment's first point.

y1

[in] Y coordinate of the segment's first point.

x2

[in] X coordinate of the segment's second point.

y2

[in] Y coordinate of the segment's second point.

clr

[in] Color in ARGB format.

LineAA

Draws a segment of a freehand line using antialiasing algorithm.

```
void LineAA(  
    const int   x1,           // X coordinate  
    const int   y1,           // Y coordinate  
    const int   x2,           // X coordinate  
    const int   y2,           // Y coordinate  
    const uint   clr,         // color  
    const uint   style=UINT_MAX // line style  
);
```

Parameters

x1

[in] X coordinate of the segment's first point.

y1

[in] Y coordinate of the segment's first point.

x2

[in] X coordinate of the segment's second point.

y2

[in] Y coordinate of the segment's second point.

clr

[in] Color in ARGB format.

style=UINT_MAX

[in] Line style is one of [ENUM_LINE_STYLE](#) enumeration's values or a custom value.

LineWu

Draws a segment of a freehand line using Wu's anti-aliasing algorithm.

```
void LineWu(  
    const int   x1,           // X coordinate  
    const int   y1,           // Y coordinate  
    const int   x2,           // X coordinate  
    const int   y2,           // Y coordinate  
    const uint   clr,         // color  
    const uint   style=UINT_MAX // line style  
);
```

Parameters

x1

[in] X coordinate of the segment's first point.

y1

[in] Y coordinate of the segment's first point.

x2

[in] X coordinate of the segment's second point.

y2

[in] Y coordinate of the segment's second point.

clr

[in] Color in ARGB format.

style=UINT_MAX

[in] Line style is one of [ENUM_LINE_STYLE](#) enumeration's values or a custom value.

LineHorizontal

Draws a segment of a horizontal line.

```
void LineHorizontal(  
    int      x1,      // X coordinate  
    int      x2,      // X coordinate  
    int      y,       // Y coordinate  
    const uint clr     // color  
);
```

Parameters

x1

[in] X coordinate of the segment's first point.

x2

[in] X coordinate of the segment's second point.

y

[in] Segment's Y coordinate.

clr

[in] Color in ARGB format.

LineStyleSet

Sets the line style.

```
void LineStyleSet(  
    const uint style    // style  
);
```

Parameters

style

[in] Line style.

Note

The input parameter can have any of ENUM_LINE_STYLE enumeration values. Besides, it is possible to create a custom line drawing style.

LineVertical

Draws a segment of a vertical line.

```
void LineVertical(  
    int      x,          // X coordinate  
    int      y1,         // Y coordinate  
    int      y2,         // Y coordinate  
    const uint clr       // color  
);
```

Parameters

x

[in] Segment's X coordinate.

y1

[in] Y coordinate of the segment's first point.

y2

[in] Y coordinate of the segment's second point.

clr

[in] Color in ARGB format.

LineThickHorizontal

Draws a horizontal segment of a freehand line having a specified width antialiasing.

```
void LineThickHorizontal(  
    const int      x1,           // X coordinate of the segment's first point  
    const int      x2,           // X coordinate of the segment's second point  
    const int      y,           // Y coordinate of the segment  
    const uint     clr,          // color  
    const int      size,         // line width  
    const uint     style,        // line style  
    ENUM_LINE_END  end_style     // line ends style  
)
```

Parameters

x1

[in] X coordinate of the segment's first point.

x2

[in] X coordinate of the segment's second point.

y

[in] Segment's Y coordinate.

clr

[in] Color in ARGB format.

size

[in] Line width.

style

[in] Line style is one of the `ENUM_LINE_STYLE` enumeration's values or a custom value.

end_style

[in] Line style is one of the [ENUM_LINE_END](#) enumeration's values.

LineThickVertical

Draws a vertical segment of a freehand line having a specified width using antialiasing algorithm.

```
void LineThickVertical(  
    const int      x,           // X coordinate of the segment  
    const int      y1,          // Y coordinate of the segment's first point  
    const int      y2,          // Y coordinate of the segment's second point  
    const uint     clr,         // color  
    const int      size,        // line width  
    const uint     style,       // line style  
    ENUM_LINE_END  end_style    // line ends style  
)
```

Parameters

x

[in] Segment's X coordinate.

y1

[in] Y coordinate of the segment's first point.

y2

[in] Y coordinate of the segment's second point.

clr

[in] Color in ARGB format.

size

[in] Line width.

style

[in] Line style is one of the `ENUM_LINE_STYLE` enumeration's values or a custom value.

end_style

[in] Line style is one of the [ENUM_LINE_END](#) enumeration's values.

LineThick

Draws a segment of a freehand line having a specified width using antialiasing algorithm.

```
void LineThick(
    const int      x1,           // X coordinate of the segment's first point
    const int      y1,           // Y coordinate of the segment's first point
    const int      x2,           // X coordinate of the segment's second point
    const int      y2,           // Y coordinate of the segment's second point
    const uint     clr,          // color
    const int      size,         // line width
    const uint     style,        // line style
    ENUM_LINE_END  end_style     // line ends style
)
```

Parameters

- x1*
[in] X coordinate of the segment's first point.
- y1*
[in] Y coordinate of the segment's first point.
- x2*
[in] X coordinate of the segment's second point.
- y2*
[in] Y coordinate of the segment's second point.
- clr*
[in] Color in ARGB format.
- size*
[in] Line width.
- style*
[in] Line style is one of the ENUM_LINE_STYLE enumeration's values or a custom value.
- end_style*
[in] Line style is one of the ENUM_LINE_END enumeration's values

ENUM_LINE_END

ID	Description
LINE_END_ROUND	Line ends are rounded.
LINE_END_BUTT	Line ends are cut.
LINE_END_SQUARE	A line ends in a filled rectangle.

LoadFromFile

Reads an image from a BMP file.

```
bool LoadFromFile(  
    const string filename    // file name  
);
```

Parameters

filename

[in] File name (including "BMP" extension).

Return Value

true - successful, otherwise - false

PixelGet

Receives color of the point with the specified coordinates.

```
uint PixelGet(  
    const int x,      // X coordinate  
    const int y      // Y coordinate  
);
```

Parameters

x

[in] Point's X coordinate.

y

[in] Point's Y coordinate.

Return Value

Point color in ARGB format.

PixelSet

Sets color of the point with the specified coordinates.

```
void PixelSet(  
    const int   x,           // X coordinate  
    const int   y,           // Y coordinate  
    const uint  clr          // color  
);
```

Parameters

x

[in] Point's X coordinate.

y

[in] Point's Y coordinate.

clr

[in] Color in ARGB format.

PixelSetAA

Draws a point using antialiasing algorithm.

```
void PixelSetAA(  
    const double x,      // X coordinate  
    const double y,      // Y coordinate  
    const uint   clr     // color  
);
```

Parameters

x

[in] Point's X coordinate.

y

[in] Point's Y coordinate.

clr

[in] Color in ARGB format.

Polygon

Draws a polygon.

```
void Polygon(  
    int&      x[],      // array of X coordinates  
    int&      y[],      // array of Y coordinates  
    const uint clr      // color  
);
```

Parameters

x[]

[in] Array of X coordinates of a polygon points.

y[]

[in] Array of Y coordinates of a polygon points.

clr

[in] Color in ARGB format.

PolygonAA

Draws a polygon using antialiasing algorithm.

```
void PolygonAA(  
    int&      x[],           // array of X coordinates  
    int&      y[],           // array of Y coordinates  
    const uint clr,          // color  
    const uint style=UINT_MAX // line style  
);
```

Parameters

x[]

[in] Array of X coordinates of a polygon points.

y[]

[in] Array of Y coordinates of a polygon points.

clr

[in] Color in ARGB format.

style=UINT_MAX

[in] Line style is one of [ENUM_LINE_STYLE](#) enumeration's values or a custom value.

PolygonWu

Draws a polygon using Wu's anti-aliasing algorithm.

```
void PolygonWu(  
    int&      x[],           // array of X coordinates  
    int&      y[],           // array of Y coordinates  
    const uint clr,          // color  
    const uint style=UINT_MAX // line style  
);
```

Parameters

x[]

[in] Array of X coordinates of a polygon points.

y[]

[in] Array of Y coordinates of a polygon points.

clr

[in] Color in ARGB format.

style=UINT_MAX

[in] Line style is one of [ENUM_LINE_STYLE](#) enumeration's values or a custom value.

PolygonThick

Draws a polygon with a specified width using antialiasing algorithm.

```
void PolygonThick(  
    const int&    x[],           // array with the X coordinates of polygon points  
    const int&    y[],           // array with the Y coordinates of polygon points  
    const uint    clr,           // color  
    const int     size,          // line width  
    const uint    style,         // line style  
    ENUM_LINE_END end_style      // line ends style  
)
```

Parameters

x[]

[in] Array of X coordinates of polygon points.

y[]

[in] Array of Y coordinates of polygon points.

clr

[in] Color in ARGB format.

size

[in] Line width.

style

[in] Line style is one of the ENUM_LINE_STYLE enumeration's values or a custom value.

end_style

[in] Line style is one of the [ENUM_LINE_END](#) enumeration's values.

PolygonSmooth

Draws a polygon with a specified width consecutively using two antialiasing algorithms. First, individual segments are smoothed based on Bezier curves. Then, the raster antialiasing algorithm is applied to the polygon built from these segments to improve the rendering quality.

```
void PolygonSmooth(
    int&          x[],           // array with the X coordinates of p
    int&          y[],           // array with the Y coordinates of p
    const uint    clr,          // color
    const int     size,          // line width
    ENUM_LINE_STYLE style=STYLE_SOLID, // line style
    ENUM_LINE_END end_style=LINE_END_ROUND, // line ends style
    double        tension=0.5,   // antialiasing parameter value
    double        step=10        // length of approximation lines
)
```

Parameters

&x[]

[in] Array of X coordinates of polygon points.

&y[]

[in] Array of Y coordinates of polygon points.

clr

[in] Color in ARGB format.

size

[in] Line width.

style=STYLE_SOLID

[in] Line style is one of the `ENUM_LINE_STYLE` enumeration's values or a custom value.

end_style=LINE_END_ROUND

[in] Line style is one of the [ENUM_LINE_END](#) enumeration's values.

tension=0.5

[in] Smoothing parameter value.

step=10

[in] Length of approximating lines.

Polyline

Draws a polyline.

```
void Polyline(  
    int&      x[],      // array of X coordinates  
    int&      y[],      // array of Y coordinates  
    const uint clr      // color  
);
```

Parameters

x[]

[in] Array of X coordinates of a polyline.

y[]

[in] Array of Y coordinates of a polyline.

clr

[in] Color in ARGB format.

PolylineAA

Draws a polyline using antialiasing algorithm.

```
void PolylineAA(  
    int&      x[],           // array of X coordinates  
    int&      y[],           // array of Y coordinates  
    const uint clr,          // color  
    const uint style=UINT_MAX // line style  
);
```

Parameters

x[]

[in] Array of X coordinates of a polyline.

y[]

[in] Array of Y coordinates of a polyline.

clr

[in] Color in ARGB format.

style=UINT_MAX

[in] Line style is one of [ENUM_LINE_STYLE](#) enumeration's values or a custom value.

PolylineWu

Draws a polyline using Wu's anti-aliasing algorithm.

```
void PolylineWu(  
    int&      x[],           // array of X coordinates  
    int&      y[],           // array of Y coordinates  
    const uint clr,          // color  
    const uint style=UINT_MAX // line style  
);
```

Parameters

x[]

[in] Array of X coordinates of a polyline.

y[]

[in] Array of Y coordinates of a polyline.

clr

[in] Color in ARGB format.

style=UINT_MAX

[in] Line style is one of [ENUM_LINE_STYLE](#) enumeration's values or a custom value.

PolylineSmooth

Draws a polyline with a specified width consecutively using two antialiasing algorithms. First, individual line segments are smoothed based on Bezier curves. Then, the raster antialiasing algorithm is applied to the polyline built from these segments to improve the rendering quality.

```
void PolylineSmooth(  
    const int&      x[],           // array with the X coordinates of po  
    const int&      y[],           // array with the Y coordinates of po  
    const uint      clr,           // color  
    const int       size,          // line width  
    ENUM_LINE_STYLE style=STYLE_SOLID, // line style  
    ENUM_LINE_END   end_style=LINE_END_ROUND, // line ends style  
    double          tension=0.5,    // antialiasing parameter value  
    double          step=10         // approximation step  
)
```

Parameters

&x[]

[in] Array of X coordinates of a polyline.

&y[]

[in] Array of Y coordinates of a polyline.

clr

[in] Color in ARGB format.

size

[in] Line width.

style=STYLE_SOLID

[in] Line style is one of the `ENUM_LINE_STYLE` enumeration's values or a custom value.

end_style=LINE_END_ROUND

[in] Line style is one of the [ENUM_LINE_END](#) enumeration's values.

tension=0.5

[in] Smoothing parameter value.

step=10

[in] Approximation step.

PolylineThick

Draws a polyline with a specified width using antialiasing algorithm.

```
void PolylineThick(  
    const int      &x[],           // array with the X coordinates of polyline points  
    const int      &y[],           // array with the Y coordinates of polyline points  
    const uint     clr,           // color  
    const int      size,          // line width  
    const uint     style,         // line style  
    ENUM_LINE_END  end_style      // line ends style  
)
```

Parameters

&x[]

[in] Array of X coordinates of a polyline.

&y[]

[in] Array of Y coordinates of a polyline.

clr

[in] Color in ARGB format.

size

[in] Line width.

style

[in] Line style is one of the ENUM_LINE_STYLE enumeration's values or a custom value.

end_style

[in] Line style is one of the [ENUM_LINE_END](#) enumeration's values

Rectangle

Draws a rectangle using two points.

```
void Rectangle(  
    int      x1,      // X coordinate  
    int      y1,      // Y coordinate  
    int      x2,      // X coordinate  
    int      y2,      // Y coordinate  
    const uint clr     // color  
);
```

Parameters

x1

[in] X coordinate of the first point forming a rectangle.

y1

[in] Y coordinate of the first point forming a rectangle.

x2

[in] X coordinate of the second point forming a rectangle.

y2

[in] Y coordinate of the second point forming a rectangle.

clr

[in] Color in ARGB format.

Resize

Resizes a graphical resource.

```
bool  Resize(  
    const int  width,      // width  
    const int  height     // height  
);
```

Parameters

width

[in] New width of a graphical resource.

height

[in] New height of a graphical resource.

Return Value

true - successful, otherwise - false

Note

When resizing, the previous image is not saved.

ResourceName

Receives the name of a graphical resource.

```
string ResourceName();
```

Return Value

name of a graphical resource

TextHeight

Receives the text height.

```
int TextHeight(  
    const string text    // text  
);
```

Parameters

text

[in] Text for measuring.

Return Value

text height in pixels

Note

The current font is used for measuring the text.

TextOut

Displays text.

```
void TextOut (
    int      x,           // X coordinate
    int      y,           // Y coordinate
    string    text,        // text
    const uint clr,        // color
    uint      alignment=0  // alignment
);
```

Parameters

x

[in] Text anchor's X coordinate.

y

[in] Text anchor's Y coordinate.

text

[in] Text to be displayed.

clr

[in] Color in ARGB format.

alignment=0

[in] Text anchoring method. See [TextOut\(\)](#) function description to learn more about anchoring methods.

Note

The current font is used to display the text.

TextSize

Receives the text size.

```
void TextSize(  
    const string text,      // text  
    int& width,             // width  
    int& height            // height  
);
```

Parameters

text

[in] Text for measuring.

width

[out] Reference to the variable for returning a text width.

height

[out] Reference to the variable for returning a text height.

Note

The current font is used to measure the text.

TextWidth

Receives the text width.

```
int TextWidth(  
    const string text    // text  
);
```

Parameters

text

[in] Text for measuring.

Return Value

text height in pixels

Note

The current font is used to measure the text.

TransparentLevelSet

Sets transparency level.

```
void TransparentLevelSet(  
    const uchar value    // value  
);
```

Parameters

value

[in] New value of the transparency level.

Note

0 stands for full transparency, while 255 - for full opacity.

Setting a transparency level affects all that was previously drawn. The specified transparency level does not affect further constructions.

Triangle

Draws a triangle.

```
void Triangle(  
    int      x1,      // X coordinate  
    int      y1,      // Y coordinate  
    int      x2,      // X coordinate  
    int      y2,      // Y coordinate  
    int      x3,      // X coordinate  
    int      y3,      // Y coordinate  
    const uint clr     // color  
);
```

Parameters

x1

[in] X coordinate of the triangle's first corner.

y1

[in] Y coordinate of the triangle's first corner.

x2

[in] X coordinate of the triangle's second corner.

y2

[in] Y coordinate of the triangle's second corner.

x3

[in] X coordinate of the triangle's third corner.

y3

[in] Y coordinate of the triangle's third corner.

clr

[in] Color in ARGB format.

TriangleAA

Draws a triangle using antialiasing algorithm.

```
void TriangleAA(  
    const int   x1,           // X coordinate  
    const int   y1,           // Y coordinate  
    const int   x2,           // X coordinate  
    const int   y2,           // Y coordinate  
    const int   x3,           // X coordinate  
    const int   y3,           // Y coordinate  
    const uint   clr,         // color  
    const uint   style=UINT_MAX // line style  
);
```

Parameters

x1

[in] X coordinate of the triangle's first corner.

y1

[in] Y coordinate of the triangle's first corner.

x2

[in] X coordinate of the triangle's second corner.

y2

[in] Y coordinate of the triangle's second corner.

x3

[in] X coordinate of the triangle's third corner.

y3

[in] Y coordinate of the triangle's third corner.

clr

[in] Color in ARGB format.

style=UINT_MAX

[in] Line style is one of [ENUM_LINE_STYLE](#) enumeration's values or a custom value.

TriangleWu

Draws a triangle using Wu's anti-aliasing algorithm.

```
void TriangleWu(  
    const int   x1,           // X coordinate  
    const int   y1,           // Y coordinate  
    const int   x2,           // X coordinate  
    const int   y2,           // Y coordinate  
    const int   x3,           // X coordinate  
    const int   y3,           // Y coordinate  
    const uint   clr,         // color  
    const uint   style=UINT_MAX // line style  
);
```

Parameters

x1

[in] X coordinate of the triangle's first corner.

y1

[in] Y coordinate of the triangle's first corner.

x2

[in] X coordinate of the triangle's second corner.

y2

[in] Y coordinate of the triangle's second corner.

x3

[in] X coordinate of the triangle's third corner.

y3

[in] Y coordinate of the triangle's third corner.

clr

[in] Color in ARGB format.

style=UINT_MAX

[in] Line style is one of [ENUM_LINE_STYLE](#) enumeration's values or a custom value.

Update

Displays changes on the screen.

```
void Update(  
    const bool  redraw=true    // flag  
);
```

Parameters

redraw=true

Flag of a chart redrawing necessity.

Width

Receives the width of a graphical resource.

```
int Width();
```

Return Value

graphical resource width

CChart

CChart is a class for simplified access to "Chart" graphic object properties.

Description

CChart class provides access to "Chart" object properties.

Declaration

```
class CChart : public CObject
```

Title

```
#include <Charts\Chart.mqh>
```

Inheritance hierarchy

CObject

CChart

Class Methods by Groups

Access to protected data	
<u>ChartID</u>	Gets identifier of the chart
General properties	
<u>Mode</u>	Gets/sets the value of "Mode" property (bars, candles, or line)
<u>Foreground</u>	Gets/sets the value of "Foreground" property
<u>Shift</u>	Gets/sets the value of "Shift" property
<u>ShiftSize</u>	Gets/sets the value of "ShiftSize" property (in percents)
<u>AutoScroll</u>	Gets/sets the value of "AutoScroll" property
<u>Scale</u>	Gets/sets the value of "Scale" property
<u>ScaleFix</u>	Gets/sets the value of "ScaleFix" property (fixed chart scale or not)
<u>ScaleFix_11</u>	Gets/sets the value of "ScaleFix_11" property (chart scale is 1:1, or not)
<u>FixedMax</u>	Gets/sets the value of "FixedMax" property (fixed maximal price)
<u>FixedMin</u>	Gets/sets the value of "FixedMin" property (fixed minimal price)

<u>ScalePPB</u>	Gets/sets the value of "ScalePPB" property (scale is "point per bar" or not)
<u>PointsPerBar</u>	Gets/sets the value of "PointsPerBar" property (in points per bar)
Show properties	
<u>ShowOHLC</u>	Gets/sets the value of "ShowOHLC" property
<u>ShowLineBid</u>	Gets/sets the value of "ShowLineBid" property
<u>ShowLineAsk</u>	Gets/sets the value of "ShowLineAsk" property
<u>ShowLastLine</u>	Gets/sets the value of "ShowLastLine" property
<u>ShowPeriodSep</u>	Gets/sets the value of "ShowPeriodSep" property (show period separators)
<u>ShowGrid</u>	Gets/sets the value of "ShowGrid" property
<u>ShowVolumes</u>	Gets/sets the value of "ShowVolumes" property (color for volumes and levels of opened positions)
<u>ShowObjectDescr</u>	Gets/sets the value of "ShowObjectDescr" property (show description for graphic objects)
<u>ShowDateScale</u>	Sets the value of "ShowDateScale" property (date scale of the chart)
<u>ShowPriceScale</u>	Sets the value of "ShowPriceScale" property (price scale of the chart)
Color properties	
<u>ColorBackground</u>	Gets/sets the value of "ColorBackground" property (background color of the chart)
<u>ColorForeground</u>	Gets/sets the value of "ColorForeground" property (color of axes, scale and OHLC strings of the chart)
<u>ColorGrid</u>	Gets/sets the value of "ColorGrid" property (color of the grid)
<u>ColorBarUp</u>	Gets/sets the value of "ColorBarUp" property (color for bull bars, their shadow and candle body outlines)
<u>ColorBarDown</u>	Gets/sets the value of "ColorBarDown" property (color for bear bars, their shadow and candle body outlines)
<u>ColorCandleBull</u>	Gets/sets the value of "ColorCandleBull" property (body color of the bull candle)

<u>ColorCandleBear</u>	Gets/sets the value of "ColorCandleBear" property (body color of the bear candle)
<u>ColorChartLine</u>	Gets/sets the value of "ColorChartLine" property (color for line chart and Doji candles)
<u>ColorVolumes</u>	Gets/sets the value of "ColorVolumes" property (color for volumes and levels of opened positions)
<u>ColorLineBid</u>	Gets/sets the value of "ColorLineBid" property (color of Bid line)
<u>ColorLineAsk</u>	Gets/sets the value of "ColorLineAsk" property (color of Ask line)
<u>ColorLineLast</u>	Gets/sets the value of "ColorLineLast" property (color of the last deal price line)
<u>ColorStopLevels</u>	Gets/sets the value of "ColorStopLevels" property (color of the SL and TP levels)
Read only properties	
<u>VisibleBars</u>	Gets total number of visible chart bars
<u>WindowsTotal</u>	Gets total number of chart windows, including the chart indicator subwindows
<u>WindowsVisible</u>	Gets visibility flag of the specified chart subwindow
<u>WindowHandle</u>	Gets window handle of the chart (HWND)
<u>FirstVisibleBar</u>	Gets the number of the first visible bar of the chart
<u>WidthInBars</u>	Gets window width in bars.
<u>WidthInPixels</u>	Gets subwindow width in pixels.
<u>HeightInPixels</u>	Gets subwindow height in pixels.
<u>PriceMin</u>	Gets minimal price of the specified subwindow
<u>PriceMax</u>	Gets maximal price of the specified subwindow
Properties	
<u>Attach</u>	Assigns the current chart to the class instance
<u>FirstChart</u>	Assigns the first chart of the client terminal to the class instance
<u>NextChart</u>	Assigns the next chart of the client terminal to the class instance
<u>Open</u>	Opens chart with specified parameters and assign it to the class instance

Detach	Detaches chart from the class instance
Close	Closes chart assigned to the class instance
BringToTop	Show chart on top of other charts
EventObjectCreate	Sets a flag to send notifications of an event of new object creation on a chart
EventObjectDelete	Sets a flag to send notifications of an event of object deletion on a chart
Indicators	
IndicatorAdd	Adds an indicator with the specified handle into a specified chart subwindow
IndicatorDelete	Removes an indicator with a specified name from the specified chart subwindow
IndicatorsTotal	Returns the number of all indicators applied to the specified chart subwindow
IndicatorName	Returns the short name of the indicator on the specified chart subwindow
Navigation	
Navigate	Navigates the chart
Access to MQL5 API	
Symbol	Gets symbol of the chart
Period	Gets period of the chart
Redraw	Redraws chart, assigned to the class instance
GetInteger	The function returns the value of the corresponding object property
SetInteger	Sets new value for the property of the integer type
GetDouble	The function returns the value of the corresponding object property
SetDouble	Sets new value for the property of the double type
GetString	The function returns the value of the corresponding object property
SetString	Sets new value for the property of the string type
SetSymbolPeriod	Changes symbol and period of the chart assigned to the class instance

<u>ApplyTemplate</u>	Applies specified template to the chart
<u>ScreenShot</u>	Creates screenshot of the specified chart and saves it to .gif file
<u>WindowOnDropped</u>	Gets chart subwindow number corresponding to the object (expert or script) drop point
<u>PriceOnDropped</u>	Gets price coordinate corresponding to the object (expert or script) drop point
<u>TimeOnDropped</u>	Gets time coordinate corresponding to the object (expert or script) drop point
<u>XOnDropped</u>	Gets X coordinate corresponding to the object (expert or script) drop point
<u>YOnDropped</u>	Gets Y coordinate corresponding to the object (expert or script) drop point
Input/Output	
virtual <u>Save</u>	Saves object parameters to file
virtual <u>Load</u>	Loads object parameters from file
virtual <u>Type</u>	Gets graphic object type identifier

Methods inherited from class CObject

Prev, Prev, Next, Next, [Compare](#)

ChartID

Returns identifier of the chart.

```
long ChartID() const
```

Return Value

Chart identifier assigned to the chart class instance. If there is no chart assigned, it returns -1.

Mode (Get Method)

Gets the value of "Mode" property (bars, candles, or line).

```
ENUM_CHART_MODE Mode() const
```

Return Value

Value of "Mode" property of the object assigned to the class instance. If there is no chart assigned, it returns [WRONG_VALUE](#).

Mode (Set Method)

Sets new value for "Mode" property (bars, candles, or line).

```
bool Mode(  
    ENUM_CHART_MODE mode    // chart mode  
)
```

Parameters

mode

[in] Chart mode (candles, bars or line) of [ENUM_CHART_MODE](#) enumeration.

Return Value

true - successful, false - cannot change the mode.

Foreground (Get Method)

Gets the value of "Foreground" property.

```
bool Foreground() const
```

Return Value

Value of "Foreground" property of the chart assigned to the class instance. If there is no chart assigned, it returns false.

Foreground (Set Method)

Sets new value for "Foreground" property.

```
bool Foreground(  
    bool foreground    // flag value  
)
```

Parameters

foreground

[in] New value for "Foreground" property.

Return Value

true - successful, false - cannot change the property.

Shift (Get Method)

Gets the value of "Shift" property.

```
bool Shift() const
```

Return Value

Value of "Shift" property of the chart assigned to the class instance. If there is no chart assigned, it returns false.

Shift (Set Method)

Sets new value for "Shift" property.

```
bool Shift(  
    bool shift    // flag value  
)
```

Parameters

shift

[in] New value for "Shift" property.

Return Value

true - successful, false - cannot change the property.

ShiftSize (Get Method)

Gets the value of "ShiftSize" property (in percents).

```
double ShiftSize() const
```

Return Value

Value of "ShiftSize" property of the chart assigned to the class instance. If there is no chart assigned, it returns [EMPTY_VALUE](#).

ShiftSize (Set Method)

Sets new value for "Shift" property (in percents).

```
bool ShiftSize(  
    double shift_size    // property value  
)
```

Parameters

shift_size

[in] New value for "ShiftSize" property (in percents).

Return Value

true - successful, false - cannot change the property.

AutoScroll (Get Method)

Gets the value of "AutoScroll" property.

```
bool AutoScroll() const
```

Return Value

Value of "AutoScroll" property of the chart assigned to the class instance. If there is no chart assigned, it returns false.

AutoScroll (Set Method)

Sets new value for "AutoScroll" property.

```
bool AutoScroll(  
    bool autoscroll    // flag value  
)
```

Parameters

autoscroll

[in] New value for "Autoscroll" property.

Return Value

true - successful, false - cannot change the property.

Scale (Get Method)

Gets the value of "Scale" property.

```
int Scale() const
```

Return Value

Value of "Scale" property of the chart assigned to the class instance. If there is no chart assigned, it returns 0.

Scale (Set Method)

Sets new value for "Scale" property.

```
bool Scale(  
    int scale    // property value  
)
```

Parameters

scale

[in] New value for "Scale" property.

Return Value

true - successful, false - cannot change the property.

ScaleFix (Get Method)

Gets the value of "ScaleFix" property (fixed chart scale or not).

```
bool ScaleFix() const
```

Return Value

Value of "ScaleFix" property of the chart assigned to the class instance. If there is no chart assigned, it returns false.

ScaleFix (Set Method)

Sets new value for "ScaleFix" property.

```
bool ScaleFix(  
    bool scale_fix    // property value  
)
```

Parameters

scale_fix

[in] New value for "ScaleFix" property.

Return Value

true - successful, false - cannot change the property.

ScaleFix_11 (Get Method)

Gets the value of "ScaleFix_11" property (chart scale is 1:1, or not).

```
bool ScaleFix_11() const
```

Return Value

Value of "ScaleFix_11" property of the chart assigned to the class instance. If there is no chart assigned, it returns false.

ScaleFix_11 (Set Method)

Sets new value for "ScaleFix_11" property.

```
bool ScaleFix_11(  
    string scale_11    // property value  
)
```

Parameters

scale_11

[in] New value for "ScaleFix_11" property.

Return Value

true - successful, false - cannot change the property.

FixedMax (Get Method)

Gets the value of "FixedMax" property (fixed maximal price).

```
double FixedMax() const
```

Return Value

Value of "FixedMax" property of the chart assigned to the class instance. If there is no chart assigned, it returns [EMPTY_VALUE](#).

FixedMax (Set Method)

Sets the new value for "FixedMax" property.

```
bool FixedMax (
    double max      // fixed maximum
)
```

Parameters

max

[in] New value for "FixedMax" property.

Return Value

true - successful, false - cannot change the property.

FixedMin (Get Method)

Gets the value of "FixedMin" property (fixed minimal price).

```
double FixedMin() const
```

Return Value

Value of "FixedMin" property of the chart assigned to the class instance. If there is no chart assigned, it returns [EMPTY_VALUE](#).

FixedMin (Set Method)

Sets new value for "FixedMin" property.

```
bool FixedMax (
    double min      // fixed minimum
)
```

Parameters

max

[in] New value for "FixedMin" property.

Return Value

true - successful, false - cannot change the property.

PointsPerBar (Get Method)

Gets the value of "PointsPerBar" property (in points per bar).

```
double PointsPerBar() const
```

Return Value

Value of "PointsPerBar" property of the chart assigned to the class instance. If there is no chart assigned, it returns [EMPTY_VALUE](#).

PointsPerBar (Set Method)

Sets new value for "PointsPerBar" property.

```
bool PointsPerBar (
    double ppb      // scale
)
```

Parameters

ppb

[in] New scale (in points per bar).

Return Value

true - successful, false - cannot change the scale.

ScalePPB (Get Method)

Gets the value of "ScalePPB" property (scale is "point per bar" or not).

```
bool ScalePPB() const
```

Return Value

Value of "ScalePPB" property of the chart assigned to the class instance. If there is no chart assigned, it returns false.

ScalePPB (Set Method)

Sets new value for "ScalePPB" property.

```
bool ScalePPB(  
    bool scale_ppb    // flag value  
)
```

Parameters

scale_ppb

[in] New value for "ScalePPB" property.

Return Value

true - successful, false - cannot change the property.

ShowOHLC (Get Method)

Gets the value of "ShowOHLC" property.

```
bool ShowOHLC() const
```

Return Value

Value of "ShowOHLC" property of the chart assigned to the class instance. If there is no chart assigned, it returns false.

ShowOHLC (Set Method)

Sets new value for "ShowOHLC" property.

```
bool ShowOHLC(  
    bool show    // property value  
)
```

Parameters

show

[in] New value for "ShowOHLC" property.

Return Value

true - success, false - cannot change the property.

ShowLineBid (Get Method)

Gets the value of "ShowLineBid" property.

```
bool ShowLineBid() const
```

Return Value

Value of "ShowLineBid" property of the char, assigned to the class instance. If there is no chart assigned, it returns false.

ShowLineBid (Set Method)

Sets new value for "ShowLineBid" property.

```
bool ShowLineBid(  
    bool show    // property value  
)
```

Parameters

show

[in] New value for "ShowLineBid" property.

Return Value

true - successful, false - cannot change the property.

ShowLineAsk (Get Method)

Gets the value of "ShowLineAsk" property.

```
bool ShowLineAsk() const
```

Return Value

Value of "ShowLineAsk" property of the chart assigned to the class instance. If there is no chart assigned, it returns false.

ShowLineAsk (Set Method)

Sets new value for "ShowLineAsk" property.

```
bool ShowLineAsk(  
    bool show // property value  
)
```

Parameters

show

[in] New value for "ShowLineAsk" property.

Return Value

true - successful, false - cannot change the property.

ShowLastLine (Get Method)

Gets the value of "ShowLastLine" property.

```
bool ShowLastLine() const
```

Return Value

Value of "ShowLastLine" property of the chart assigned to the class instance. If there is no chart assigned, it returns false.

ShowLastLine (Set Method)

Sets new value for "ShowLastLine" property.

```
bool ShowLastLine (  
    bool show // property value  
)
```

Parameters

show

[in] New value for "ShowLastLine" property.

Return Value

true - successful, false - cannot change the property.

ShowPeriodSep (Get Method)

Gets the value of "ShowPeriodSep" property (show period separators).

```
bool ShowPeriodSep() const
```

Return Value

Value of "ShowPeriodSep" property of the chart assigned to the class instance. If there is no chart assigned, it returns false.

ShowPeriodSep (Set Method)

Sets new value for "ShowPeriodSep" property.

```
bool ShowPeriodSep(  
    bool show // property value  
)
```

Parameters

show

[in] New value for "ShowPeriodSep" property.

Return Value

true - successful, false - cannot change the property.

ShowGrid (Get Method)

Gets the value of "ShowGrid" property.

```
bool ShowGrid() const
```

Return Value

Value of "ShowGrid" property of the chart assigned to the class instance. If there is no chart assigned, it returns false.

ShowGrid (Set Method)

Sets new value for "ShowGrid" property.

```
bool ShowGrid(  
    bool show    // property value  
)
```

Parameters

show

[in] New value for "ShowGrid" property.

Return Value

true - successful, false - cannot change the property.

ShowVolumes (Get Method)

Gets the value of "ShowVolumes" property.

```
bool ShowVolumes() const
```

Return Value

Value of "ShowVolumes" property of the chart assigned to the class instance. If there is no chart assigned, it returns false.

ShowVolumes (Set Method)

Sets new value for "ShowVolumes" property.

```
bool ShowVolumes (  
    bool show // property value  
)
```

Parameters

show

[in] New value for "ShowVolumes" property.

Return Value

true - successful, false - cannot change the property.

ShowObjectDescr (Get Method)

Gets the value of "ShowObjectDescr" property (show description for graphic objects).

```
bool ShowObjectDescr() const
```

Return Value

Value of "ShowObjectDescr" property of the chart assigned to the class instance. If there is no chart assigned, it returns false.

ShowObjectDescr (Set Method)

Sets new value for "ShowObjectDescr" property.

```
bool ShowObjectDescr(  
    bool show    // property value  
)
```

Parameters

show

[in] New value for "ShowObjectDescr" property.

Return Value

true - successful, false - cannot change the property.

ShowDateScale

Sets new value for "ShowDateScale" property.

```
bool ShowDateScale(  
    bool show    // property value  
)
```

Parameters

show

[in] New value for "ShowDateScale" property.

Return Value

true - successful, false - cannot change the property.

ShowPriceScale

Sets new value for "ShowPriceScale" property.

```
bool ShowPriceScale(  
    bool show    // property value  
)
```

Parameters

show

[in] New value for "ShowPriceScale" property.

Return Value

true - successful, false - cannot change the property.

ColorBackground (Get Method)

Gets the value of "ColorBackground" property (background color of the chart).

```
color ColorBackground() const
```

Return Value

Value of "ColorBackground" property of the chart assigned to the class instance. If there is no chart assigned, it returns [CLR_NONE](#).

ColorBackground (Set Method)

Sets new value for "ColorBackground" property.

```
bool ColorBackground(  
    color new_color    // color  
)
```

Parameters

new_color

[in] New background color.

Return Value

true - successful, false - cannot change the color.

ColorForeground (Get Method)

Gets the value of "ColorForeground" property (color of axes, scale and OHLC strings of the chart).

```
color ColorForeground() const
```

Return Value

Value of "ColorForeground" property of the chart assigned to the class instance. If there is no chart assigned, it returns [CLR_NONE](#).

ColorForeground (Set Method)

Sets new value for "ColorForeground" property (for axes, scale, and OHLC string).

```
bool ColorForeground(  
    color new_color    // color  
)
```

Parameters

new_color

[in] New color for axes, scale and OHLC string.

Return Value

true - successful, false - cannot change the color.

ColorGrid (Get Method)

Gets the value of "ColorGrid" property (color of the grid).

```
color ColorGrid() const
```

Return Value

Value of "ColorGrid" property of the chart assigned to the class instance. If there is no chart assigned, it returns [CLR_NONE](#).

ColorGrid (Set Method)

Sets new value for "ColorGrid" property.

```
bool ColorGrid(  
    color new_color    // color  
)
```

Parameters

new_color
[in] New grid color.

Return Value

true - successful, false - cannot change the color.

ColorBarUp (Get Method)

Gets the value of "ColorBarUp" property (color for bullish bars, their shadow, and candle body outlines).

```
color ColorBarUp() const
```

Return Value

Value of "ColorBarUp" property of the chart assigned to the class instance. If there is no chart assigned, it returns [CLR_NONE](#).

ColorBarUp (Set Method)

Sets new value for "ColorBarUp" property.

```
bool ColorBarUp(  
    color new_color    // color  
)
```

Parameters

new_color

[in] New color for bullish bars, their shadow and candle body outlines.

Return Value

true - successful, false - cannot change the color.

ColorBarDown (Get Method)

Gets the value of "ColorBarDown" property (color for bearish bars, their shadow, and candle body outlines).

```
color ColorBarDown() const
```

Return Value

Value of "ColorBarDown" property of the chart assigned to the class instance. If there is no chart assigned, it returns [CLR_NONE](#).

ColorBarDown (Set Method)

Sets new value for "ColorBarDown" property.

```
bool ColorBarDown(  
    color new_color    // color  
)
```

Parameters

new_color

[in] New color for bearish bars, their shadow, and candle body outlines.

Return Value

true - successful, false - cannot change the color.

ColorCandleBull (Get Method)

Gets the value of "ColorCandleBull" property (body color of the bullish candle).

```
color ColorCandleBull() const
```

Return Value

Value of "ColorCandleBull" property of the chart assigned to the class instance. If there is no chart assigned, it returns [CLR_NONE](#).

ColorCandleBull (Set Method)

Sets new value for "ColorCandleBull" property.

```
bool ColorCandleBull(  
    color new_color    // color  
)
```

Parameters

new_color

[in] New color of the bullish candle body.

Return Value

true - successful, false - cannot change the color.

ColorCandleBear (Get Method)

Gets the value of "ColorCandleBear" property (body color of the bearish candle).

```
color ColorCandleBear() const
```

Return Value

Value of "ColorCandleBear" property of the chart assigned to the class instance. If there is no chart assigned, it returns [CLR_NONE](#).

ColorCandleBear (Set Method)

Sets new value for "ColorCandleBear" property.

```
bool ColorCandleBear(  
    color new_color    // color  
)
```

Parameters

new_color

[in] New color of the bearish candle body.

Return Value

true - successful, false - cannot change the color.

ColorChartLine (Get Method)

Gets the value of "ColorChartLine" property (color for line chart and Doji candles).

```
color ColorChartLine() const
```

Return Value

Value of "ColorChartLine" property of the chart assigned to the class instance. If there is no chart assigned, it returns [CLR_NONE](#).

ColorChartLine (Set Method)

Sets new value for "ColorChartLine" property.

```
bool ColorChartLine(  
    color new_color    // color  
)
```

Parameters

new_color

[in] New color of the chart lines and Doji candles.

Return Value

true - successful, false - cannot change the color.

ColorVolumes (Get Method)

Gets the value of "ColorVolumes" property (color for volumes and levels of opened positions).

```
color ColorVolumes() const
```

Return Value

Value of "ColorVolumes" property of the chart assigned to the class instance. If there is no chart assigned, it returns [CLR_NONE](#).

ColorVolumes (Set Method)

Sets new value for "ColorVolumes" property.

```
bool ColorVolumes (
    color new_color    // color
)
```

Parameters

new_color

[in] New color of the volumes and open position levels.

Return Value

true - successful, false - cannot change the color.

ColorLineBid (Get Method)

Gets the value of "ColorLineBid" property (color of Bid line).

```
color ColorLineBid() const
```

Return Value

Value of "ColorLineBid" property of the chart assigned to the class instance. If there is no chart assigned, it returns [CLR_NONE](#).

ColorLineBid (Set Method)

Sets new value for "ColorLineBid" property.

```
bool ColorLineBid(  
    color new_color    // color  
)
```

Parameters

new_color

[in] New color for Bid line.

Return Value

true - successful, false - cannot change the color.

ColorLineAsk (Get Method)

Gets the value of "ColorLineAsk" property (color of Ask line).

```
color ColorLineAsk() const
```

Return Value

Value of "ColorLineAsk" property of the chart assigned to the class instance. If there is no chart assigned, it returns [CLR_NONE](#).

ColorLineAsk (Set Method)

Sets new value for "ColorLineAsk" property.

```
bool ColorLineAsk(  
    color new_color    // color  
)
```

Parameters

new_color

[in] New color for Ask line.

Return Value

true - successful, false - cannot change the color.

ColorLineLast (Get Method)

Gets the value of "ColorLineLast" property (color of the last deal price line).

```
color ColorLineLast() const
```

Return Value

Value of "ColorLineLast" property of the chart assigned to the class instance. If there is no chart assigned, it returns [CLR_NONE](#).

ColorLineLast (Set Method)

Sets new value for "ColorLineLast" property.

```
bool ColorLineLast(  
    color new_color    // color  
)
```

Parameters

new_color

[in] New color of the last deal price line.

Return Value

true - successful, false - cannot change the color.

ColorStopLevels (Get Method)

Gets the value of "ColorStopLevels" property (color of the SL and TP levels).

```
color ColorStopLevels() const
```

Return Value

Value of "ColorStopLevels" property of the chart assigned to the class instance. If there is no chart assigned, it returns [CLR_NONE](#).

ColorStopLevels (Set Method)

Sets new value for "ColorStopLevels" property.

```
bool ColorStopLevels(  
    color new_color    // color  
)
```

Parameters

new_color

[in] New color of the Stop Loss and Take Profit price levels.

Return Value

true - successful, false - cannot change the color.

VisibleBars

Gets total number of visible chart bars.

```
int VisibleBars() const
```

Return Value

Gets total number of visible bars of the chart assigned to the class instance. If there is no chart assigned, it returns 0.

WindowsTotal

Gets total number of chart windows, including the chart indicator subwindows.

```
int WindowsTotal() const
```

Return Value

Total number of windows, including the chart indicator subwindows, assigned to the class instance.
If there is no chart assigned, it returns 0.

WindowIsVisible

Gets visibility flag of the specified chart subwindow.

```
bool WindowIsVisible(  
    int num      // subwindow  
) const
```

Parameters

num

[in] Subwindow number (0 means main window).

Return Value

Returns visibility flag of the specified chart subwindow assigned to the chart instance. If there is no chart assigned, it returns false.

WindowHandle

Gets window handle of the chart (HWND).

```
int WindowHandle() const
```

Return Value

Window handle of the chart assigned to the chart instance. If there is no chart assigned, it returns [INVALID_HANDLE](#).

FirstVisibleBar

Gets the number of the first visible bar of the chart.

```
int FirstVisibleBar() const
```

Return Value

Number of the first visible bar of the chart assigned to the class instance. If there is no chart assigned, it returns -1.

WidthInBars

Gets chart width in bars.

```
int WidthInBars() const
```

Return Value

Width in chart bars of the chart assigned to the class instance. If there is no chart assigned, it returns 0.

WidthInPixels

Gets chart width in pixels.

```
int WidthInPixels() const
```

Return Value

Width in pixels of the chart assigned to the chart instance. If there is no chart assigned, it returns 0.

HeightInPixels

Gets window height in pixels.

```
int HeightInPixels(  
    int num    // subwindow  
) const
```

Parameters

num

[in] Checked subwindow number (0 means main window).

Return Value

Window height in pixels of the chart assigned to the class instance. If there is no chart assigned, it returns 0.

PriceMin

Gets window minimal price.

```
double PriceMin(  
    int num      // subwindow  
) const
```

Parameters

num

[in] Subwindow number (0 means main window).

Return Value

Window minimal price value of the chart assigned to the class instance. If there is not chart assigned, it returns [EMPTY_VALUE](#).

PriceMax

Gets window maximal price.

```
double PriceMax(  
    int num      // subwindow  
    ) const
```

Parameters

num

[in] Subwindow number (0 means main window).

Return Value

Window maximal price value of the chart assigned to the class instance. If there is not chart assigned, it returns [EMPTY_VALUE](#).

Attach

Assigns the current chart to the class instance.

```
void Attach()
```

Attach

Assigns the specified chart to the class instance.

```
void Attach(  
    long chart    // chart identifier  
)
```

Parameters

chart

[in] Identifier of the assigned chart.

FirstChart

Assigns the first chart of the client terminal to the class instance.

```
void FirstChart()
```

NextChart

Assigns the next chart (following the already assigned one) to the class instance.

```
void NextChart()
```

Open

Opens chart with specified parameters and assigns it to the class instance.

```
long Open(  
    const string      symbol_name,      // symbol  
    ENUM_TIMEFRAMES  timeframe         // period  
)
```

Parameters

symbol_name

[in] Chart symbol. [NULL](#) means the symbol of the current chart (to which an expert is attached).

timeframe

[in] Chart timeframe (from [ENUM_TIMEFRAMES](#) enumeration). 0 means the current timeframe.

Return Value

chart identifier.

Detach

Detaches chart from the class instance.

```
void Detach()
```

Close

Closes chart assigned to the class instance.

```
void Close()
```

BringToTop

Show chart on top of other charts.

```
bool BringToTop() const
```

Return Value

true - successful, false - error.

EventObjectCreate

Sets a flag to send notifications of [events](#) of a graphical object creation.

```
bool EventObjectCreate(  
    bool flag    // flag  
)
```

Parameters

flag

[in] New value of a flag to send notifications of events of a graphical object creation.

Return Value

true - successful, false - cannot change the flag.

EventObjectDelete

Sets a flag to send notifications of [events](#) of a graphical object deletion.

```
bool EventObjectDelete(  
    bool flag    // flag  
)
```

Parameters

flag

[in] New value of a flag to send notifications of events of a graphical object deletion.

Return Value

true - successful, false - cannot change the flag.

IndicatorAdd

Adds an indicator with the specified handle into a specified chart window.

```
bool IndicatorAdd(  
    int    sub_win      // number of the subwindow  
    int    handle       // handle of the indicator  
);
```

Parameters

sub_win

[in] The number of the chart subwindow. 0 means the main chart window. if the number of a non-existing window is specified, a new window will be created.

handle

[in] The handle of the indicator.

Return Value

The function returns true in case of success, otherwise it returns false. In order to obtain information about the [error](#), call the [GetLastError\(\)](#) function.

See also

[IndicatorDelete\(\)](#), [IndicatorsTotal\(\)](#), [IndicatorName\(\)](#).

IndicatorDelete

Removes an indicator with a specified name from the specified chart window.

```
bool IndicatorDelete(  
    int          sub_win      // number of the subwindow  
    const string name        // short name of the indicator  
);
```

Parameters

sub_win

[in] Number of the chart subwindow. 0 denotes the main chart subwindow.

const name

[in] The short name of the indicator which is set in the [INDICATOR_SHORTNAME](#) property with the [IndicatorSetString\(\)](#) function. To get the short name of an indicator, use the [IndicatorName\(\)](#) function.

Return Value

Returns true in case of successful deletion of the indicator. Otherwise it returns false. To get [error](#) details, use the [GetLastError\(\)](#) function.

Note

If two indicators with identical short names exist in the chart subwindow, the first one in a row will be deleted.

If other indicators on this chart are based on the values of the indicator that is being deleted, such indicators will also be deleted.

Do not confuse the indicator short name and the file name that is specified when creating an indicator using functions [iCustom\(\)](#) and [IndicatorCreate\(\)](#). If the short name of an indicator is not set explicitly, then the name of the file containing the source code of the indicator will be specified during compilation.

Deletion of an indicator from a chart does not mean that its calculation part will be deleted from the terminal memory. To release the indicator handle, use the [IndicatorRelease\(\)](#) function.

The indicator's short name should be formed correctly. It will be written to the [INDICATOR_SHORTNAME](#) property using the [IndicatorSetString\(\)](#) function. It is recommended that the short name should contain values of all the input parameters of the indicator, because the indicator to be deleted from the chart by the [IndicatorDelete\(\)](#) function is identified by the short name.

See also

[IndicatorAdd\(\)](#), [IndicatorsTotal\(\)](#), [IndicatorName\(\)](#), [iCustom\(\)](#), [IndicatorCreate\(\)](#), [IndicatorSetString\(\)](#).

IndicatorsTotal

Returns the number of all indicators applied to the specified chart window.

```
int IndicatorsTotal(  
    long   chart_id, // chart identifier  
    int    sub_win   // number of the subwindow  
);
```

Parameters

chart_id

[in] Chart identifier. 0 denotes the main chart.

sub_win

[in] Number of the chart subwindow. 0 denotes the main chart window.

Return Value

The number of indicators in the specified chart window. To get [error](#) details, use the [GetLastError\(\)](#) function.

Note

The function allows going searching through all the indicators attached to the chart. The number of all the windows of the chart can be obtained from the [CHART_WINDOWS_TOTAL](#) property using the [GetInteger\(\)](#) function.

See also

[IndicatorAdd\(\)](#), [IndicatorDelete\(\)](#), [IndicatorsTotal\(\)](#), [iCustom\(\)](#), [IndicatorCreate\(\)](#), [IndicatorSetString\(\)](#).

IndicatorName

Returns the short name of the indicator by the index in the indicators list on the specified chart window.

```
string IndicatorName(  
    int    sub_win    // number of the subwindow  
    int    index       // index of the indicator in the list of indicators added to the  
);
```

Parameters

sub_win

[in] Number of the chart subwindow. 0 denotes the main chart window.

index

[in] Index of the indicator in the list of indicators. The numeration of indicators start with zero, i.e. the first indicator in the list has the 0 index. To obtain the number of indicators in the list, use the [IndicatorsTotal\(\)](#) function.

Return Value

The short name of the indicator which is set in the [INDICATOR_SHORTNAME](#) property with the [IndicatorSetString\(\)](#) function. To get [error](#) details, use the [GetLastError\(\)](#) function.

Note

Do not confuse the indicator short name and the file name that is specified when creating an indicator using functions [iCustom\(\)](#) and [IndicatorCreate\(\)](#). If the short name of an indicator is not set explicitly, then the name of the file containing the source code of the indicator will be specified during compilation.

The indicator's short name should be formed correctly. It will be written to the [INDICATOR_SHORTNAME](#) property using the [IndicatorSetString\(\)](#) function. It is recommended that the short name should contain values of all the input parameters of the indicator, because the indicator to be deleted from the chart by the [IndicatorDelete\(\)](#) function is identified by the short name.

See also

[IndicatorAdd\(\)](#), [IndicatorDelete](#), [IndicatorsTotal](#), [iCustom\(\)](#), [IndicatorCreate\(\)](#), [IndicatorSetString\(\)](#).

Navigate

Shifts the chart.

```
bool Navigate(  
    ENUM_CHART_POSITION position,    // position  
    int shift=0                     // shift  
)
```

Parameters

position

[in] Chart position (from [ENUM_CHART_POSITION](#) enumeration), relative to which a shift is performed.

shift=0

[in] Number of bars to shift.

Return Value

true - successful, false - cannot shift the chart.

Symbol

Gets chart symbol name.

```
string Symbol() const
```

Return Value

Symbol name of the chart, assigned to the class instance. If there is no chart assigned, it returns "".

Period

Gets period of the chart.

```
ENUM_TIMEFRAMES Period() const
```

Return Value

Period of the chart (from [ENUM_TIMEFRAMES](#)) assigned to the class instance. If there is no chart assigned, it returns 0.

Redraw

Redraws chart assigned to the class instance.

```
void Redraw()
```

GetInteger

The function returns the value of the corresponding chart property. The chart property should be of the [integer](#) type. There are two variants of the function.

1. Immediately returns the property value.

```
long GetInteger(  
    ENUM_CHART_PROPERTY_INTEGER prop_id,          // property identifier  
    int sub_window=0                             // subwindow number  
) const
```

2. If successful, puts the value of property to the specified variable of integer type, passed by reference as last parameter.

```
bool GetInteger(  
    ENUM_CHART_PROPERTY_INTEGER prop_id,          // property identifier  
    int sub_window,                             // subwindow number  
    long& value                                  // link to the variable  
) const
```

Parameters

prop_id

[in] Property identifier ([ENUM_CHART_PROPERTY_INTEGER](#) enumeration).

sub_window

[in] Chart subwindow number.

value

[in] Link to the variable that receives the value of the requested property.

Return Value

Value of property of the chart assigned to the class instance. If there is not any chart assigned, it returns -1.

For the second variant, the function returns true, if this property is maintained and the value has been placed into the value variable, otherwise it returns false. To read more about the [error](#), call [GetLastError\(\)](#).

SetInteger

Sets new value for the property of the integer type.

```
bool SetInteger(  
    ENUM_CHART_PROPERTY_INTEGER prop_id,    // property identifier  
    long value                               // value  
)
```

Parameters

prop_id

[in] Chart property identifier (from [ENUM_CHART_PROPERTY_INTEGER](#) enumeration).

value

[in] New value of the property.

Return Value

true - successful, false - cannot change the integer property.

GetDouble

The function returns the value of the corresponding chart property. The object property should be of the double type. There are two variants of the function.

1. Immediately returns the property value.

```
double GetDouble (
    ENUM_CHART_PROPERTY_DOUBLE prop_id,      // property identifier
    int sub_window=0                        // subwindow number
) const
```

2. If successful, puts the value of property to the specified variable of double type, passed by reference as last parameter.

```
bool GetDouble (
    ENUM_CHART_PROPERTY_DOUBLE prop_id,      // property identifier
    int sub_window,                        // subwindow number
    double& value                          // link to the variable
) const
```

Parameters

prop_id

[in] Chart property identifier (from [ENUM_CHART_PROPERTY_DOUBLE](#) enumeration).

sub_window

[in] Chart subwindow number.

value

[in] Variable of the double type that received the value of the requested property.

Return Value

Value of property of the chart assigned to the class instance. If there is not any chart assigned, it returns [EMPTY_VALUE](#).

For the second variant the function, it returns true if the property value is received, otherwise returns false. To read more about the [error](#), call [GetLastError\(\)](#).

SetDouble

Sets new value for the chart property of the double type.

```
bool SetDouble(  
    ENUM_CHART_PROPERTY_DOUBLE prop_id,    // property identifier  
    double value                          // new value  
)
```

Parameters

prop_id

[in] Chart property identifier (from [ENUM_CHART_PROPERTY_DOUBLE](#) enumeration).

value

[in] New value for the property.

Return Value

true - successful, false - cannot change the double property.

GetString

The function returns the value of the corresponding chart property. The chart property should be of the string type. There are two variants of the function.

1. Immediately returns the property value.

```
string GetString(  
    ENUM_CHART_PROPERTY_STRING prop_id    // property identifier  
) const
```

2. If successful, puts the value of property to the specified variable of string type, passed by reference as last parameter.

```
bool GetString(  
    ENUM_CHART_PROPERTY_STRING prop_id,    // property identifier  
    string& value                          // link to the variable  
) const
```

Parameters

prop_id

[in] Chart property identifier (from [ENUM_CHART_PROPERTY_STRING](#) enumeration).

value

[in] Link to the variable that receives the value of the requested property.

Return Value

Value of a chart property assigned to the class instance. If there is no chart assigned, it returns "".

For the second variant, the function returns true, if this property is maintained and the value has been placed into the value variable, otherwise it returns false. To read more about the [error](#), call [GetLastError\(\)](#).

SetString

Sets new value for the chart property of the string type.

```
bool SetString(  
    ENUM_CHART_PROPERTY_STRING prop_id,    // property identifier  
    string value                          // value  
)
```

Parameters

prop_id

[in] Chart property identifier (from [ENUM_CHART_PROPERTY_STRING](#) enumeration).

value

[in] New value for the property.

Return Value

true - successful, false - cannot change the string property.

SetSymbolPeriod

Changes symbol and period of the chart assigned to the class instance.

```
bool SetSymbolPeriod(  
    const string      symbol_name,      // symbol  
    ENUM_TIMEFRAMES timeframe          // period  
)
```

Parameters

symbol_name

[in] New chart symbol. [NULL](#) means the symbol of the current chart (to which an expert is attached).

timeframe

[in] New chart timeframe (from [ENUM_TIMEFRAMES](#) enumeration). 0 means the current chart timeframe.

Return Value

true - successful, false - cannot change the property.

ApplyTemplate

Applies specified template to the chart.

```
bool ApplyTemplate(  
    const string filename    // template  
)
```

Parameters

filename

[in] File name of the template.

Return Value

true - successful, false - cannot apply the template.

ScreenShot

Creates a screenshot of the specified chart in its current state in .gif format.

```
bool  ScreenShot(  
    string      filename,           // file name  
    int         width,              // width  
    int         height,             // height  
    ENUM_ALIGN_MODE align_mode=ALIGN_RIGHT // align type  
) const
```

Parameters

filename

[in] File name for screenshot.

width

[in] Screenshot width in pixels.

height

[in] Screenshot height in pixels.

align_mode=ALIGN_RIGHT

[in] Align mode, if screenshot is narrow.

Return Value

true - successful, false - error.

WindowOnDropped

Gets chart subwindow number corresponding to the object (expert or script) drop point.

```
int WindowOnDropped() const
```

Return Value

Chart subwindow number of the object drop point. 0 means main chart window.

PriceOnDropped

Gets price coordinate corresponding to the object (expert or script) drop point.

```
double PriceOnDropped() const
```

Return Value

Price coordinate of the object drop point.

TimeOnDropped

Gets time coordinate corresponding to the object (expert or script) drop point.

```
datetime TimeOnDropped() const
```

Return Value

Time coordinate of the object drop point.

XOnDropped

Gets X coordinate corresponding to the object (expert or script) drop point.

```
int XOnDropped() const
```

Return Value

X coordinate of the object drop point.

YOnDropped

Gets Y coordinate corresponding to the object (expert or script) drop point.

```
int YOnDropped() const
```

Return Value

Y coordinate of the object drop point.

Save

Saves object parameters to file.

```
virtual bool Save(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] handle of the binary file already opened by [FileOpen\(...\)](#) function.

Return Value

true - successful, false - error.

Load

Loads object parameters from file.

```
virtual bool Load(  
    int file_handle    // file handle  
)
```

Parameters

file_handle

[in] handle of the binary file already opened by [FileOpen\(...\)](#) function.

Return Value

true - successful, false - error.

Type

Returns type identifier.

```
virtual int Type() const
```

Return Value

Type identifier (0x1111 for CChart).

Graphics

The graphics library contains classes and global functions for quick plotting of custom charts.

The library provides convenient ready-made solutions for building axes, curves, as well as the methods for quick access to changing common properties of a custom chart.

The graphics library is placed to the Include\Graphics folder of the terminal's working directory.

Class	Description
<u>CAxis</u>	Class for working with coordinate axes
<u>ColorGenerator</u>	Class specifying the default color scheme
<u>CCurve</u>	Class for working with curves
<u>CGraphic</u>	Base class for creating custom charts

GraphPlot

Functions for quick curve plotting.

Version for plotting a single curve using Y coordinates.

```
string GraphPlot(  
    const double    &y[],           // Y coordinates  
    ENUM_CURVE_TYPE type=CURVE_POINTS // curve type  
)
```

Note

Y array indices are used as X coordinates for the curve.

Version for plotting a single curve using X and Y coordinates

```
string GraphPlot(  
    const double    &x[],           // X coordinates  
    const double    &y[],           // Y coordinates  
    ENUM_CURVE_TYPE type=CURVE_POINTS // curve type  
)
```

Version for plotting two curves using X and Y coordinates

```
string GraphPlot(  
    const double    &x1[],           // X coordinates  
    const double    &y1[],           // Y coordinates  
    const double    &x2[],           // X coordinates  
    const double    &y2[],           // Y coordinates  
    ENUM_CURVE_TYPE type=CURVE_POINTS // curve type  
)
```

Version for plotting three curves using X and Y coordinates

```
string GraphPlot(  
    const double    &x1[],           // X coordinates  
    const double    &y1[],           // Y coordinates  
    const double    &x2[],           // X coordinates  
    const double    &y2[],           // Y coordinates  
    const double    &x3[],           // X coordinates  
    const double    &y3[],           // Y coordinates  
    ENUM_CURVE_TYPE type=CURVE_POINTS // curve type  
)
```

Version for plotting a curve using CPoint2D points coordinates

```

string  GraphPlot(
    const CPoint2D    &points[],           // curve coordinates
    ENUM_CURVE_TYPE  type=CURVE_POINTS    // curve type
)

```

Version for plotting two curves using CPoint2D points coordinates

```

string  GraphPlot(
    const CPoint2D    &points1[],          // curve coordinates
    const CPoint2D    &points2[],          // curve coordinates
    ENUM_CURVE_TYPE  type=CURVE_POINTS    // curve type
)

```

Version for plotting three curves using CPoint2D points coordinates

```

string  GraphPlot(
    const CPoint2D    &points1[],          // curve coordinates
    const CPoint2D    &points2[],          // curve coordinates
    const CPoint2D    &points3[],          // curve coordinates
    ENUM_CURVE_TYPE  type=CURVE_POINTS    // curve type
)

```

Version for plotting a curve using the pointer to CurveFunction

```

string  GraphPlot(
    CurveFunction      function,            // pointer to the function
    const double       from,               // initial value of the argument
    const double       to,                 // final value of the argument
    const double       step,               // increment by the argument
    ENUM_CURVE_TYPE    type=CURVE_POINTS   // curve type
)

```

Version for plotting two curves using the pointers to the CurveFunction functions

```

string  GraphPlot(
    CurveFunction      function1,          // pointer to the function
    CurveFunction      function2,          // pointer to the function
    const double       from,               // initial value of the argument
    const double       to,                 // final value of the argument
    const double       step,               // increment by the argument
    ENUM_CURVE_TYPE    type=CURVE_POINTS   // curve type
)

```

Version for plotting three curves using the pointers to the CurveFunction functions

```

string  GraphPlot (
    CurveFunction  function1,           // pointer to the function
    CurveFunction  function2,           // pointer to the function
    CurveFunction  function3,           // pointer to the function
    const double   from,                // initial value of the argument
    const double   to,                  // final value of the argument
    const double   step,                // increment by the argument
    ENUM_CURVE_TYPE type=CURVE_POINTS // curve type
)

```

Parameters

&x[]

[in] X coordinates.

&y[]

[in] Y coordinates.

&x1[]

[in] X coordinates for the first curve.

&y1[]

[in] Y coordinates for the first curve.

&x2[]

[in] X coordinates for the second curve.

&y2[]

[in] Y coordinates for the second curve.

&x3[]

[in] X coordinates for the third curve.

&y3[]

[in] Y coordinates for the third curve.

&points[]

[in] Coordinates of the curve dots.

&points1[]

[in] Coordinates of the first curve dots.

&points2[]

[in] Coordinates of the second curve dots.

&points3[]

[in] Coordinates of the third curve dots.

function

[in] Pointer to the CurveFunction function.

function1

[in] Pointer to the first function.

function2

[in] Pointer to the second function.

function3

[in] Pointer to the third function.

from

[in] Corresponds to the first X coordinate.

to

[in] Corresponds to the last X coordinate.

step

[in] Parameter for calculating the X coordinates.

type=CURVE_POINTS

[in] Curve type.

Return Value

Name of a graphical resource.

CAxis

CAxis is an auxiliary graphics library class for working with the coordinate axes.

Description

The CAxis class receives and stores various parameters of the coordinate axes. The class implements the ability to auto scale the coordinate axes dynamically.

Declaration

```
class CAxis
```

Title

```
#include <Graphics\Axis.mqh>
```

Class methods

Method	Description
AutoScale	Get/set the auto-scaling flag
Min	Get/set the minimum axis value
Max	Get/set the maximum axis value
Step	Get the step value by axis
Name	Get/set the axis name
Color	Get/set the axis color
ValuesSize	Get/set the size of the axis numbers
ValuesWidth	Get/set the maximum displayed length of the axis numbers
ValuesFormat	Get/set the format of the axis numbers
ValuesDateTimeMode	Get the format of converting a date into a string.
ValuesFunctionFormat	Get the pointer to the function defining the format of displaying values on the axis.
ValuesFunctionFormatCBData	Get the pointer to the object that may contain additional data on converting axis values.
NameSize	Get/set the font size of the axis name
ZeroLever	Get/set the "zero lever" value
DefaultStep	Get/set the initial step value by axis
MaxLabels	Get/set the maximum amount of numbers on the axis

<u>MinGrace</u>	Get/set the "tolerance" value for the axis minimum
<u>MaxGrace</u>	Get/set the "tolerance" value for the axis maximum
<u>SelectAxisScale</u>	Auto scale the axis.

AutoScale (Get method)

Returns the flag defining the need for auto-scale.

```
bool AutoScale()
```

Return Value

The flag value.

Note

true — perform auto-scaling.

false — do not perform auto-scaling.

AutoScale (Set method)

Sets the flag defining the need for auto-scale.

```
void AutoScale (  
    const bool auto    // flag value  
)
```

Parameters

auto

[in]

Note

true — perform auto-scaling.

false — do not perform auto-scaling.

Min (Get method)

Returns the minimum axis value.

```
double Min()
```

Return Value

Minimum axis value.

Min (Set method)

Sets the minimum axis value.

```
void Min(  
    const double min    // minimum value  
)
```

Parameters

min

[in] Minimum value.

Max (Get method)

Returns the maximum axis value.

```
double Max()
```

Return Value

Maximum axis value.

Max (Set method)

Sets the maximum axis value.

```
void Max(  
    const double max // maximum value  
)
```

Parameters

max

[in] Maximum axis value.

Step (Get method)

Return the step value by axis.

```
double Step()
```

Return Value

Step value.

Name (Get method)

Returns the axis name.

```
string Name()
```

Return Value

Axis name.

Name (Set method)

Sets the axis name.

```
void Name(  
    const string name    // axis name  
)
```

Parameters

name

[in] Axis name.

Color (Get method)

Returns the axis color.

```
color Color()
```

Return Value

Axis color.

Color (Set method)

Sets the axis color.

```
void Color(  
    const color clr    // axis color  
)
```

Parameters

clr

[in] Axis color.

ValuesSize (Get method)

Returns the size of the axis numbers.

```
int ValuesSize()
```

Return Value

Size of the axis numbers.

ValuesSize (Set method)

Sets the size of the axis numbers.

```
void ValuesSize(  
    const int size    // size of the axis numbers  
)
```

Parameters

size

[in] Size of the axis numbers

ValuesWidth (Get method)

Returns the maximum allowed length in pixels for displaying the axis numbers.

```
int ValuesWidth()
```

Return Value

Length of the axis numbers in pixels.

Note

If a length in pixels for a specified number exceeds the maximum allowed display length, it is truncated and ends in dots.

ValuesWidth (Set method)

Sets the maximum allowed length in pixels for displaying the axis numbers.

```
void ValuesWidth(  
    const int width // maximum allowed length in pixels  
)
```

Parameters

width

[in] Maximum allowed length of the axis numbers.

Note

If a length in pixels for a specified number exceeds the maximum allowed display length, it is truncated and ends in dots.

ValuesFormat (Get method)

Returns the format of the axis numbers.

```
string ValuesFormat()
```

Return Value

Number format.

ValuesFormat (Set method)

Sets the format of the axis numbers.

```
void ValuesFormat(  
    const string format      // format of the axis numbers  
)
```

Parameters

format

[in] Format of the axis numbers.

ValuesDateTimeMode (Get method)

Get the format of converting a date into a string.

```
int ValuesDateTimeMode()
```

Return Value

Format of converting a date into a string.

ValuesDateTimeMode (Set method)

Set the format of converting a date into a string.

```
void ValuesDateTimeMode(  
    const int mode // format of converting a date into a string  
)
```

Parameters

mode

[in] Conversion format.

Note

Find out more about the formats of converting a date into a string in the [TimeToString\(\)](#) function description.

ValuesFunctionFormat (Get method)

Get the pointer to the function defining the format of displaying values on the axis.

```
DoubleToStringFunction ValuesFunctionFormat ()
```

Return Value

Pointer to the function defining the format of displaying values on the axis.

ValuesFunctionFormat (Set method)

Set the pointer to the function defining the format of displaying values on the axis.

```
void ValuesFunctionFormat (  
    DoubleToStringFunction func    // function for converting numerical values into  
)
```

Parameters

func

[in] Custom function for converting numerical values into a string.

Example:

The format of displaying X axis values has been changed using the following code:

```

//+-----+
//|                                     DateAxisGraphic.mqh |
//|                                     Copyright 2016, MetaQuotes Software Corp. |
//|                                     https://www.mql5.com |
//+-----+
#include <Graphics\Graphic.mqh>
//--- array for store values
double arrX[];
double arrY[];
//+-----+
//| Custom function for create values on X-axis |
//+-----+
string TimeFormat(double x,void *cbdata)
{
    return(TimeToString((datetime)arrX[ArraySize(arrX)-(int)x-1]));
}
//+-----+
void OnStart()
{
    MqlRates rates[];
    CopyRates(Symbol(),Period(),0,100,rates);
    ArraySetAsSeries(rates,true);
    int size=ArraySize(rates);
    ArrayResize(arrX,size);
    ArrayResize(arrY,size);
    for(int i=0; i<size;++i)
    {
        arrX[i]=(double)rates[i].time;
        arrY[i]=rates[i].close;
    }
    //--- create graphic
    CGraphic graphic;
    if(!graphic.Create(0,"DateAxisGraphic",0,30,30,780,380))
    {
        graphic.Attach(0,"DateAxisGraphic");
    }
    //--- create curve
    CCurve *curve=graphic.CurveAdd(arrY,CURVE_LINES);
    //--- gets the X-axis
    CAxis *xAxis=graphic.XAxis();
    //--- sets the X-axis properties
    xAxis.AutoScale(false);
    xAxis.Type(AXIS_TYPE_CUSTOM);
    xAxis.ValuesFunctionFormat(TimeFormat);
    xAxis.DefaultStep(20.0);
    //--- plot
    graphic.CurvePlotAll();
    graphic.Update();
}

```

ValuesFunctionFormatCBData (Get method)

Get the pointer to the object that may contain additional data on converting axis values.

```
void* ValuesFunctionFormatCBData()
```

Return Value

The pointer to the object that may contain additional data on converting axis values.

ValuesFunctionFormatCBData (Set method)

Set the pointer to the class object that may contain additional data on converting axis values.

```
void ValuesFunctionFormatCBData(  
    void* cbdata    // pointer to the class object  
)
```

Parameters

cbdata

[in] Pointer to any class object containing additional data on converting axis values

NameSize (Get method)

Returns the font size of the axis name.

```
int NameSize()
```

Return Value

Font size of the axis name.

NameSize (Set method)

Sets the font size of the axis name.

```
void NameSize(  
    const int size    // font size of the axis name  
)
```

Parameters

size

[in] Font size of the axis name.

ZeroLever (Get method)

Returns the "zero lever" value.

```
double ZeroLever()
```

Return Value

"Zero lever".

Note

The value is used to define when the axis scale range should be expanded to include a zero value.

ZeroLever (Set method)

Sets the "zero lever" value.

```
void ZeroLever(  
    const double value    // "zero lever" value  
)
```

Parameters

value

[in] "Zero lever" value.

Note

The value is used to define when the axis scale range should be expanded to include a zero value.

DefaultStep (Get method)

Returns the initial step value by axis

```
double DefaultStep()
```

Return Value

Step by axis.

DefaultStep (Set method)

Sets the initial step value by axis

```
void DefaultStep(  
    const double value    // step by axis  
)
```

Parameters

value

[in] Initial step value by axis.

MaxLabels (Get method)

Returns the maximum allowed amount of numbers displayed on the axis.

```
double MaxLabels()
```

Return Value

Maximum amount of numbers on the axis.

MaxLabels (Set method)

Sets the maximum allowed amount of numbers displayed on the axis.

```
void MaxLabels(  
    const double value // maximum number  
)
```

Parameters

value

[in] Maximum allowed amount of numbers displayed on the axis

MinGrace (Get method)

Returns the "tolerance" applied to the axis minimum.

```
double MinGrace()
```

Return Value

"Tolerance" value for the axis minimum.

Note

This value is expressed as part of the overall axial length. For example, suppose that the axis values are located within 4.0 to 16.0, then its length is 12.0. If MinGrace is equal to 0.1, then 10% of the axis length (or 1.2) is subtracted from the minimum value. As a result, the axis covers the interval from 2.8 to 16.0.

MinGrace (Set method)

Sets the "tolerance" applied to the axis minimum.

```
void MinGrace(  
    const double value    // "tolerance" value  
)
```

Parameters

value

[in] "Tolerance" applied to the axis minimum.

Note

This value is expressed as part of the overall axial length. For example, suppose that the axis values are located within 4.0 to 16.0, then its length is 12.0. If MinGrace is equal to 0.1, then 10% of the axis length (or 1.2) is subtracted from the minimum value. As a result, the axis covers the interval from 2.8 to 16.0.

MaxGrace (Get method)

Returns the "tolerance" applied to the axis maximum.

```
double MaxGrace()
```

Return Value

"Tolerance" value for the axis maximum.

Note

This value is expressed as part of the overall axial length. For example, suppose that the axis values are located within 4.0 to 16.0, then its length is 12.0. If MaxGrace is equal to 0.1, then 10% of the axis length (or 1.2) is added to the maximum value. As a result, the axis covers the interval from 4.0 to 17.2.

MaxGrace (Set method)

Sets the "tolerance" applied to the axis maximum.

```
void MaxGrace(  
    const double value    // "tolerance" value  
)
```

Parameters

value

[in] "Tolerance" value applied to the axis maximum.

Note

This value is expressed as part of the overall axial length. For example, suppose that the axis values are located within 4.0 to 16.0, then its length is 12.0. If MinGrace is equal to 0.1, then 10% of the axis length (or 1.2) is subtracted from the minimum value. As a result, the axis covers the interval from 2.8 to 16.0.

SelectAxisScale

Auto scale the axis.

```
void SelectAxisScale()
```

CColorGenerator

CColorGenerator class is an auxiliary graphics library class for working with the color palette.

Description

The CColorGenerator class contains the initial color palette used for curves by default (if a color is not specified by a user).

If all colors from the initial palette are used already, new colors are automatically generated and the palette is refilled.

Declaration

```
class CColorGenerator
```

Title

```
#include <Graphics\ColorGenerator.mqh>
```

Class methods

Method	Description
Next	Returns the next color from the palette
Reset	Resets the generator

Next

Returns the next color from the palette.

```
uint Next ()
```

Return Value

Color.

Note

If all colors from the palette have already been passed through, new colors are automatically generated in order to replace the old ones in the palette.

Reset

Resets the generator.

```
void Reset()
```

CCurve

The CCurve class works with the properties of the curves generated on the chart.

Description

The CCurve class sets, installs and receives the coordinates and various properties of the curves when working with the CGraphic class.

There are three curve plotting modes: dots, lines and histogram. Separate parameters are implemented for each plotting mode in the class.

Declaration

```
class CCurve : public CObject
```

Title

```
#include <Graphics\Curve.mqh>
```

Inheritance hierarchy

[CObject](#)

CCurve

Class methods

Method	Description
Type	Get the curve type
Name	Get the curve name
Color	Get the curve color
XMax	Get the maximum value of the X function
XMin	Get the minimum value of the X function
YMax	Get the maximum value of the Y function
YMin	Get the minimum value of the Y function
Size	Get the number of dots defining a curve
PointsSize	Get/set the linear size of dots defining a curve
PointsFill	Get/set the flag for filling dots defining a curve
PointsColor	Get/set the dot filling color
GetX	Gets X values of all curve dots to the array
GetY	Gets Y values of all curve dots to the array

<u>LineStyle</u>	Get/set a line style when plotting a curve using lines
<u>LinesIsSmooth</u>	Get/set the smoothing flag when drawing using lines
<u>LinesSmoothTension</u>	Get/set the curve smoothing parameter when drawing using lines
<u>LinesSmoothStep</u>	Get/set the length of the approximating lines for smoothing when plotting by lines
<u>LinesWidth</u>	Get/set a line width when plotting a curve using lines
<u>HistogramWidth</u>	Get/set the width of columns when plotting using a histogram
<u>CustomPlotCBData</u>	Get/set the pointer to the object to be used in the custom curve plotting mode.
<u>CustomPlotFunction</u>	Get/set the pointer to the function implementing the custom curve plotting mode.
<u>PointsType</u>	Get/set the flag pointing at the type of dots used when plotting a dotted curve.
<u>StepsDimension</u>	Get/set the value indicating the dimension used in step-type curve rendering.
<u>TrendLineCoefficients</u>	Get/set trend line ratios for writing them into an array.
<u>TrendLineColor</u>	Get/set a color of a trend line for a curve.
<u>TrendLineVisible</u>	Get/set the trend line visibility flag.
<u>Update</u>	Update the curve coordinates.
<u>Visible</u>	Get/set the flag defining if a function is visible on the chart.

Methods inherited from class CObject

Prev, Prev, Next, Next, [Save](#), [Load](#), [Compare](#)

Type

Return the curve type.

```
ENUM_CURVE_TYPE Type ()
```

Return Value

Curve type.

Name

Returns the curve name.

```
string Name()
```

Return Value

Curve name.

Color

Returns the curve color.

```
uint Color()
```

Return Value

Curve color.

XMax

Returns the maximum value of the X function (real numbers only).

```
double XMax()
```

Return Value

Maximum real number among all the function arguments.

XMin

Returns the minimum value of the X function (real numbers only).

```
double XMin()
```

Return Value

Minimum real number among all the function arguments.

YMax

Returns the maximum value of the Y function (real numbers only).

```
double YMax()
```

Return Value

Maximum value of the Y function (real numbers only).

YMin

Returns the minimum value of the Y function (real numbers only).

```
double YMin()
```

Return Value

Minimum value of the Y function (real numbers only).

Size

Returns the number of dots defining the curve.

```
int Size()
```

Return Value

Number of dots defining the curve.

PointSize (Get method)

Returns the linear size (in pixels) of dots used in plotting the curve.

```
int PointSize()
```

Return Value

Size of dots defining the curve in pixels.

PointSize (Set method)

Sets the linear size (in pixels) of dots used in plotting the curve.

```
void PointSize(  
    const int size    // dot size in pixels  
)
```

Parameters

size

[in] Linear size (in pixels) of dots used in plotting the curve.

PointsFill (Get method)

Returns a flag determining if a filling for dots defining a curve should be performed.

```
bool PointsFill ()
```

Return Value

The flag value.

Note

true — perform a filling

false — do not perform a filling

PointsFill (Set method)

Sets a flag determining if a filling for dots defining a curve should be performed.

```
void PointsFill (  
    const bool fill    // flag value  
)
```

Parameters

fill

[in] Flag value.

Note

true — perform a filling

false — do not perform a filling

PointsColor (Get method)

Returns the dot filling color.

```
uint PointsColor ()
```

Return Value

Color of filling dots defining the curve.

PointsColor (Set method)

Sets the dot filling color

```
void PointsColor (  
    const uint clr      //dot filling color  
)
```

Parameters

clr

[in] Color of filling dots defining the curve.

GetX

Gets X values of all curve dots to the array.

```
void GetX(  
    double& x[]    // array for writing X values  
)
```

Parameters

`x[]`

[out] Array for getting X values of all curve dots.

Note

Each curve dot is defined by a couple of X and Y values. These values are not coordinates in pixels for drawing in the [CGraphic](#) class.

GetY

Gets Y values of all curve dots to the array.

```
void GetY(  
    double& y[]    // array for writing Y values  
)
```

Parameters

y[]

[out] Array for getting Y values of all curve dots.

Note

Each curve dot is defined by a couple of X and Y values. These values are not coordinates in pixels for drawing in the [CGraphic](#) class.

LineStyle (Get method)

Returns a line style when plotting a curve using lines.

```
ENUM_LINE_STYLE LineStyle()
```

Return Value

Line style.

LineStyle (Set method)

Sets a line style when plotting a curve using lines.

```
void LineStyle (  
    ENUM_LINE_STYLE style    // line style  
)
```

Parameters

style

[in] Line style.

LinesIsSmooth (Get method)

Returns a flag defining if smoothing should be done when plotting a curve by lines.

```
bool LinesIsSmooth()
```

Return Value

Flag value

Note

true — perform smoothing

false — do not perform smoothing

LinesIsSmooth (Set method)

Sets a flag defining if smoothing should be done when plotting a curve by lines.

```
void LinesIsSmooth(  
    const bool smooth // flag value  
)
```

Parameters

smooth

[in] Flag value

Note

true — perform smoothing

false — do not perform smoothing

LinesSmoothTension (Get method)

Returns the curve smoothing parameter when drawing using lines.

```
double LinesSmoothTension()
```

Return Value

Smoothing parameter value

Note

The 'tension' value is within the (0.0; 1.0] range.

LinesSmoothTension (Set method)

Sets the curve smoothing parameter when drawing using lines.

```
void LinesSmoothTension (  
    const double tension    // parameter value  
)
```

Parameters

tension

[in] Smoothing parameter value.

Note

The 'tension' value is within the (0.0; 1.0] range.

LinesSmoothStep (Get method)

Returns the length of the approximating lines for smoothing when plotting by lines.

```
double LinesSmoothStep()
```

Return Value

Length of approximating lines in pixels.

LinesSmoothStep (Set method)

Sets the length of the approximating lines for smoothing when plotting by lines.

```
void LinesSmoothStep(  
    const double step    // line length  
)
```

Parameters

step

[in] Length of approximating lines

LinesEndStyle (Set method)

Get the flag indicating [lines end plotting style](#) when using lines to plot a curve.

```
ENUM_LINE_END LinesEndStyle()
```

Return Value

A value of the flag indicating lines end plotting style when using lines to plot a curve.

LinesEndStyle (Get method)

Set the flag indicating lines end plotting style when using lines to plot a curve.

```
void LinesEndStyle(  
    ENUM_LINE_END end_style // flag value  
)
```

Parameters

end_style

[in] A value of the flag indicating line end plotting style when using lines to plot a curve.

LineWidth (Get method)

Get lines width when plotting a curve using lines.

```
int LineWidth()
```

Return Value

Lines width.

LineWidth (Set method)

Set lines width when plotting a curve using lines.

```
void LineWidth(  
    const int width // lines width  
)
```

Parameters

width

[in] Lines width when plotting a curve using lines.

Example:

A line width has been changed using the following code:

```

//+-----+
//|                                     CandleGraphic.mq5 |
//|                                     Copyright 2016, MetaQuotes Software Corp. |
//|                                     https://www.mql5.com |
//+-----+
#include <Graphics\Graphic.mqh>
//+-----+
//| Script program start function |
//+-----+
void OnStart()
{
    double x[] = { -100,-40,-10,20,30,40,50,60,70,80,120 };
    double y[] = { -5,4,-10,23,17,18,-9,13,17,4,9 };
//--- create graphic
CGraphic graphic;
if (!graphic.Create(0,"ThickLineGraphic",0,30,30,780,380))
{
    graphic.Attach(0,"ThickLineGraphic");
}
//--- create curve
CCurve *curve=graphic.CurveAdd(x,y,CURVE_LINES);
//--- sets the curve properties
curve.LinesSmooth(true);
curve.LinesStyle(STYLE_DASH);
curve.LinesEndStyle(LINE_END_ROUND);
curve.LinesWidth(10);
//--- plot
graphic.CurvePlotAll();
graphic.Update();
}

```

HistogramWidth (Get method)

Returns the width of columns when plotting using a histogram.

```
int HistogramWidth()
```

Return Value

Column width in pixels.

HistogramWidth (Set method)

Sets the width of columns when plotting using a histogram.

```
void HistogramWidth(  
    const int width // column width  
)
```

Parameters

width

[in] Column width in pixels.

CustomPlotCBData (Get method)

Get the pointer to the object to be used in the custom curve plotting mode.

```
void* CustomPlotCBData()
```

Return Value

Pointer to the object for the custom curve plotting mode.

CustomPlotCBData (Set method)

Set the pointer to the object to be used in the custom curve plotting mode.

```
void CustomPlotCBData(  
    void* cldata    // pointer to the object  
)
```

Parameters

cldata

[in] The pointer to the object to be used in the custom curve plotting mode

CustomPlotFunction (Get method)

Get the pointer to the function implementing the custom curve plotting mode.

```
PlotFuction CustomPlotFunction()
```

Return Value

Pointer to the function implementing the custom curve plotting mode.

CustomPlotFunction (Set method)

Set the pointer to the function implementing the custom curve plotting mode.

```
void CustomPlotFunction(  
    PlotFuction func    // pointer to the function  
)
```

Parameters

func

[in] Pointer to the function implementing the custom curve plotting mode

Example:

This curve consisting of bars is built using the following code:

```

//+-----+
//|                                     CandleGraphic.mq5 |
//|               Copyright 2016, MetaQuotes Software Corp. |
//|               https://www.mql5.com |
//+-----+

    graphic.YAxis().Min((int)min);
//--- plot
    graphic.CurvePlotAll();
    graphic.Update();
}
```

PointsType (Get method)

Get the flag pointing at the type of dots used when plotting a dotted curve.

```
ENUM_POINT_TYPE PointsType()
```

Return Value

A value of the flag indicating a type of dots.

PointsType (Set method)

Set the flag pointing at the type of dots used when plotting a dotted curve.

```
void PointsType(  
    ENUM_POINT_TYPE type    // flag value  
)
```

Parameters

type

[in] A value of the flag pointing at the type of dots used when plotting a dotted curve.

StepsDimension (Get method)

Get the value indicating the dimension used in step-type curve rendering.

```
int StepsDimension()
```

Return Value

Dimension used in step-type curve rendering.

StepsDimension (Set method)

Set the value indicating the dimension used in step-type curve rendering.

```
void StepsDimension(  
    const int dimension    // dimension  
)
```

Parameters

dimension

[in] Dimension (0 or 1).

Note

0 — x (the horizontal line is followed by the vertical one).

1 — y (the vertical line is followed by the horizontal one).

TrendLineCoefficients (Get method)

Get trend line ratios for writing them into an array.

```
double& TrendLineCoefficients ()
```

Return Value

Trend line ratios.

TrendLineCoefficients (Set method)

Set trend line ratios for writing then into an array.

```
void TrendLineCoefficients (  
    double& coefficients[]    // array for writing ratios  
)
```

Parameters

coefficients[]

[out] Array for writing ratios.

TrendLineColor (Get method)

Get a color of a trend line for a curve.

```
uint TrendLineColor()
```

Return Value

Color of the trend line.

TrendLineColor (Set method)

Set a color of a trend line for a curve.

```
void TrendLineColor(  
    const uint clr    // trend line color  
)
```

Parameters

clr

[in] Line color

TrendLineVisible (Get method)

Get the trend line visibility flag.

```
bool TrendLineVisible()
```

Return Value

A value of the flag that specifies if a trend line is visible.

TrendLineVisible (Set method)

Set the trend line visibility flag.

```
void TrendLineVisible(  
    const bool visible // flag value  
)
```

Parameters

visible

[in] A value of the trend line visibility flag.

Example:

Below is the code of the mentioned trend line and its plotting on the chart:

```

//+-----+
//|                                     TrendLineGraphic.mq5 |
//|               Copyright 2016, MetaQuotes Software Corp. |
//|               https://www.mql5.com |
//+-----+
#include <Graphics\Graphic.mqh>
//+-----+
//| Script program start function |
//+-----+
void OnStart()
{
    double x[]={12.0,11.5,11.0,12.0,10.5,10.0,9.0,8.5,10.0,8.5,10.0,8.0,9.5,10.0,15.0};
    double y[]={130.0,165.0,150.0,150.0,140.0,198.0,220.0,215.0,225.0,190.0,170.0,160.0};
//--- create graphic
CGraphic graphic;
if(!graphic.Create(0,"TrendLineGraphic",0,30,30,780,380))
{
    graphic.Attach(0,"TrendLineGraphic");
}
//--- create curve
CCurve *curve=graphic.CurveAdd(x,y,CURVE_POINTS);
//--- sets the curve properties
curve.TrendLineVisible(true);
curve.TrendLineColor(ColorToARGB(clrRed));
//--- plot
graphic.CurvePlotAll();
graphic.Update();
}

```

Update

Update the curve coordinates.

The version for working by Y coordinate. Passed array indexes are used as X coordinates here.

```
void Update(  
    const double& y[] // Y coordinates  
)
```

This version uses X and Y coordinates.

```
void Update(  
    const double& x[], // X coordinates  
    const double& y[] // Y coordinates  
)
```

The version for working with CPoint2D points.

```
void Update(  
    const CPoint2D& points[] // Curve coordinates  
)
```

The version for working with a pointer to the CurveFunction function.

```
void Update(  
    CurveFunction function, // pointer to the function describing a curve  
    const double from,      // initial value of the function argument  
    const double to,        // final value of the function argument  
    const double step       // argument increment  
)
```

Parameters

x[]

[in] X coordinates.

y[]

[in] Y coordinates.

points[]

[in] Curve coordinates.

function

[in] A pointer to the function describing a curve

from

[in] Initial value of the function argument

to

[in] End value of the function argument

step

[in] Argument increment

Visible (Get method)

Get the flag defining if a function is visible on the chart.

```
void Visible(  
    const bool visible    //  
)
```

Return Value

A value of the flag defining a function visibility on the chart.

Visible (Set method)

Set the flag defining if a function is visible on the chart.

```
void Visible(  
    const bool visible    // flag value  
)
```

Parameters

visible

[in] A value of the flag defining a function visibility on the chart.

CGraphic

CGraphic is a base class for creating custom charts.

Description

The CGraphic class provides numerous aspects of working with custom charts.

The class stores the main chart elements, sets their parameters and performs plotting.

Also, the class stores the curves for the chart and provides various display options.

Declaration

```
class CGraphic
```

Title

```
#include <Graphics\Graphic.mqh>
```

Class methods

Method	Description
<u>Create</u>	Create a graphical resource bound to a chart object
<u>Destroy</u>	Remove a chart and destroy a graphical resource
<u>Update</u>	Display implemented changes
<u>ChartObjectName</u>	Get the name of an object bound to a chart
<u>ResourceName</u>	Get the graphical resource name
<u>XAxis</u>	Get the pointer to the X axis
<u>YAxis</u>	Get the pointer to the Y axis
<u>GapSize</u>	Get/set the size of indents between the chart elements
<u>BackgroundColor</u>	Get/set a background color
<u>BackgroundMain</u>	Get/set a chart header
<u>BackgroundMainSize</u>	Get/set a sub-header font size
<u>BackgroundMainColor</u>	Get/set a chart header color
<u>BackgroundSub</u>	Get/set a sub-header
<u>BackgroundSubSize</u>	Get/set a sub-header font size
<u>BackgroundSubColor</u>	Get/set a chart sub-header color

<u>GridLineColor</u>	Get/set a grid line color
<u>GridBackgroundColor</u>	Get/set a grid background color
<u>GridCircleRadius</u>	Get/set the dot radius in the grid nodes
<u>GridCircleColor</u>	Get/set the dot color in the grid nodes
<u>GridHasCircle</u>	Get/set the dot plotting flag in the grid nodes
<u>GridAxisLineColor</u>	Get the value of a real chart axes color.
<u>HistoryNameWidth</u>	Get/set the maximum allowed length for displaying a curve name
<u>HistoryNameSize</u>	Get/set the font size of a curve name
<u>HistorySymbolSize</u>	Get/set a size of notational convention symbols
<u>TextAdd</u>	Add a text to the chart
<u>LineAdd</u>	Add a line to the chart
<u>CurveAdd</u>	Create and add a curve to the chart
<u>CurvePlot</u>	Plot a previously created curve by index
<u>CurvePlotAll</u>	Plot all previously created curves
<u>CurveTotal</u>	Get the number of curves added to the chart
<u>CurveGetByIndex</u>	Get a curve by a specified index
<u>CurveGetByName</u>	Get a curve by a specified name
<u>CurveRemoveByIndex</u>	Remove a curve by a specified index.
<u>CurveRemoveByName</u>	Remove a curve by a specified name.
<u>CurvesTotal</u>	Get the number of curves for the given chart.
<u>MarksToAxisAdd</u>	Add a scale mark to the chart axis
<u>MajorMarkSize</u>	Get/set the size of the scale's ticks on the chart axis
<u>FontSet</u>	Set the current font parameters
<u>FontGet</u>	Get the current font parameters
<u>Attach</u>	Get/set a graphical resource and bind it to the CGraphic class instance
<u>CalculateMaxMinValues</u>	Calculate (re-calculate) minimum and maximum chart values on both axes.
<u>Height</u>	Get a chart height in pixels.
<u>IndentDown</u>	Get/set a chart indent from the lower border.
<u>IndentLeft</u>	Get/set a chart indent from the left border.

<u>IndentRight</u>	Get/set a chart indent from the right border.
<u>IndentUp</u>	Get/set a chart indent from the upper border.
<u>Redraw</u>	Redraw the chart.
<u>ResetParameters</u>	Reset the chart redrawing parameters.
<u>ScaleX</u>	Scale the value by X axis.
<u>ScaleY</u>	Scale the value by Y axis.
<u>SetDefaultParameters</u>	Set the chart parameters to default values.
<u>Width</u>	Get the chart width in pixels.

Create

Creates a graphical resource bound to a chart object.

```
bool Create(  
    const long   chart,      // chart ID  
    const string name,      // name  
    const int    subwin,    // sub-window index  
    const int    x1,        // x1 coordinate  
    const int    y1,        // y1 coordinate  
    const int    x2,        // x2 coordinate  
    const int    y2         // y1 coordinate  
)
```

Parameters

chart

[in] Chart ID.

name

[in] Name.

subwin

[in] Sub-window index.

x1

[in] X1 coordinate.

y1

[in] Y1 coordinate.

x2

[in] X2 coordinate.

y2

[in] Y2 coordinate.

Destroy

Removes a chart and destroys a graphical resource.

```
void Destroy()
```

Update

Displays implemented changes.

```
void Update(  
    const bool  redraw=true    // flag  
)
```

Parameters

redraw=true

[in] Flag value

ChartObjectName

Gets the name of an object bound to a chart.

```
string ChartObjectName()
```

Return Value

Name of an object bound to a chart.

ResourceName

Receives the name of a graphical resource.

```
string ResourceName()
```

Return Value

Name of a graphical resource.

XAxis

Returns the pointer to the X axis.

```
CAxis *XAxis ()
```

Return Value

Pointer to the X axis.

YAxis

Returns the pointer to the Y axis.

```
CAxis *YAxis ()
```

Return Value

Pointer to the Y axis.

GapSize (Get method)

Returns the size of indents between the chart elements.

```
int GapSize()
```

Return Value

Indent size in pixels.

GapSize (Set method)

Sets the size of indents between the chart elements.

```
void GapSize(  
    const int size    // indent size  
)
```

Parameters

size

[in] Indent size in pixels.

BackgroundColor (Get method)

Returns the background color.

```
color BackgroundColor()
```

BackgroundColor (Set method)

Sets the background color.

```
void BackgroundColor(  
    const color clr    // background color  
)
```

Parameters

clr

[in] Background color.

BackgroundMain (Get method)

Returns a chart header

```
string BackgroundMain()
```

BackgroundMain (Set method)

Sets a chart header text.

```
void BackgroundMain(  
    const string main    // header text  
)
```

Parameters

main

[in] Chart header text

BackgroundMainSize (Get method)

Returns the header size.

```
int BackgroundMainSize()
```

Return Value

Header font size.

BackgroundMainSize (Set method)

Sets the header size.

```
void BackgroundMainSize(  
    const int size    // header size  
)
```

Parameters

size

[in] Header font size.

BackgroundMainColor (Get method)

Returns the header color.

```
color BackgroundMainColor ()
```

Return Value

Header color.

BackgroundMainColor (Set method)

Sets the header color.

```
void BackgroundMainColor (  
    const color clr      // header color  
)
```

Parameters

clr

[in] Header color.

BackgroundSub (Get method)

Returns the sub-header.

```
string BackgroundSub ()
```

Return Value

Sub-header text.

BackgroundSub (Set method)

Sets the sub-header text.

```
void BackgroundSub (Set method) (  
    const string sub // sub-header text  
)
```

Parameters

sub

[in] Sub-header text.

BackgroundSubSize (Get method)

Returns the sub-header font size

```
int BackgroundSubSize()
```

BackgroundSubSize (Get method)

Sets the sub-header size

```
void BackgroundSubSize(  
    const int size // sub-header font size  
)
```

Parameters

size

[in] Sub-header font size

BackgroundSubColor (Get method)

Returns the sub-header color.

```
color BackgroundSubColor()
```

BackgroundSubColor (Set method)

Sets the sub-header color.

```
void BackgroundSubColor(  
    const color clr    // sub-header color  
)
```

Parameters

clr

[in] Sub-header color.

GridLineColor (Get method)

Returns the grid line color

```
color GridLineColor()
```

Return Value

Grid line color.

GridLineColor (Set method)

Sets the grid line color.

```
void GridLineColor(  
    const color clr    // line color  
)
```

Parameters

clr

[in] Grid line color.

GridBackgroundColor (Get method)

Returns the grid background color

```
color GridBackgroundColor ()
```

Return Value

Grid background color

GridBackgroundColor (Set method)

Sets the grid background color

```
void GridBackgroundColor (  
    const color clr      // grid background color  
)
```

Parameters

clr

[in] Grid background color

GridCircleRadius (Get method)

Returns radius of dots in the grid nodes.

```
int GridCircleRadius ()
```

Return Value

Dot radius in pixels.

GridCircleRadius (Set method)

Sets the dot radius in the grid nodes

```
void GridCircleRadius (  
    const int r      // radius  
)
```

Parameters

r

[in] Dot radius in pixels.

GridCircleColor (Get method)

Returns color of dots in the grid nodes.

```
color GridCircleColor()
```

Return Value

Dot color.

GridCircleColor (Set method)

Sets the dot color in the grid nodes.

```
void GridCircleColor(  
    const color clr    // dot color  
)
```

Parameters

clr

[in] Dot color.

GridHasCircle (Get method)

Returns the flag defining whether the dots in the grid nodes should be displayed.

```
bool GridHasCircle()
```

Return Value

The flag value.

Note

true — display the dots

false — do not display the dots

GridHasCircle (Set method)

Sets the flag defining whether the dots in the grid nodes should be displayed.

```
void GridHasCircle(  
    const bool has  
)
```

Parameters

has

[in] Flag value.

Note

true — display the dots

false — do not display the dots

GridAxisLineColor (Get method)

Get the value of a real chart axes color.

```
uint GridAxisLineColor()
```

Return Value

Color of real chart axes.

GridAxisLineColor (Set method)

Set the value of a real chart axes color.

```
void GridAxisLineColor(  
    const uint clr // chart axes color  
)
```

Parameters

clr

[in] Color of real chart axes.

HistoryNameWidth (Get method)

Returns the maximum allowed length for displaying a curve name.

```
int HistoryNameWidth()
```

Return Value

Maximum length in pixels.

Note

If the curve name exceeds the maximum allowed length, it is truncated and dots are added to its end.

HistoryNameWidth (Set method)

Sets the maximum allowed length for displaying a curve name.

```
void HistoryNameWidth(  
    const int width // maximum length  
)
```

Parameters

width

[in] Maximum length in pixels.

Note

If the curve name exceeds the maximum allowed length, it is truncated and dots are added to its end.

HistoryNameSize (Get method)

Returns the font size of the curve name.

```
int HistoryNameSize()
```

Return Value

Font size of the curve name.

HistoryNameSize (Set method)

Sets the font size of the curve name.

```
void HistoryNameSize (Set method) (  
    const int size // name font size  
)
```

Parameters

size

[in] Name font size.

HistorySymbolSize (Get method)

Returns a size of a chart's notational convention symbols

```
int HistorySymbolSize()
```

Return Value

Size of notational convention symbols

HistorySymbolSize (Set method)

Sets a size of a chart's notational convention symbols

```
void HistorySymbolSize(  
    const int size // symbol size  
)
```

Parameters

size

[in] Size of notational convention symbols.

TextAdd

Adds a text to a chart.

Version for working with X and Y coordinates

```
void TextAdd(  
    const int      x,           // X coordinate  
    const int      y,           // Y coordinate  
    const string   text,        // text  
    const uint     clr,         // color  
    const uint     alignment=0  // alignment  
)
```

Version for CPoint

```
void TextAdd(  
    const CPoint   &point,      // point coordinate  
    const string   text,        // text  
    const uint     clr,         // color  
    const uint     alignment=0  // alignment  
)
```

Parameters

x

[in] X coordinate.

y

[in] Y coordinate.

&point

[in] Point coordinate.

text

[in] Text.

clr

[in] Color.

alignment=0

[in] Alignment.

LineAdd

Adds a line to a chart.

This version uses X and Y coordinates

```
void LineAdd(  
    const int   x1,           // x1 coordinate  
    const int   y1,           // y1 coordinate  
    const int   x2,           // x2 coordinate  
    const int   y2,           // y2 coordinate  
    const uint  clr,          // color  
    const uint  style         // style  
)
```

Version for CPoint

```
void LineAdd2(  
    const CPoint &point1,     // first point coordinate  
    const CPoint &point2,     // second point coordinate  
    const uint  clr,          // color  
    const uint  style         // style  
)
```

Parameters

x1

[in] X1 coordinate.

y1

[in] Y1 coordinate.

x2

[in] X2 coordinate.

y2

[in] Y2 coordinate.

&point1

[in] First point coordinate.

&point2

[in] Second point coordinate.

clr

[in] Color.

style

[in] Style.

CurveAdd

Create and add a new curve to the chart.

This version uses the Y coordinate (a curve color is set automatically)

```
CCurve* CurveAdd(
    const double    &y[],           // Y coordinates
    ENUM_CURVE_TYPE type,           // curve type
    const string    name=NULL       // curve name
)
```

Note

Y array indices are used as X coordinates for the curve.

This version uses the X and Y coordinates (a curve color is set automatically)

```
CCurve* CurveAdd(
    const double    &x[],           // X coordinates
    const double    &y[],           // Y coordinates
    ENUM_CURVE_TYPE type,           // curve type
    const string    name=NULL       // curve name
)
```

The version for working with CPoint2D dots (curve color is set automatically)

```
CCurve* CurveAdd(
    const CPoint2D  &points[],       // dot coordinates
    ENUM_CURVE_TYPE type,           // curve type
    const string    name=NULL       // curve name
)
```

Version for working with the pointer to the CurveFunction function (curve color is set automatically)

```
CCurve* CurveAdd(
    CurveFunction    function,       // pointer to the function
    const double     from,           // initial value of the argument
    const double     to,             // final value of the argument
    const double     step,           // increment by the argument
    ENUM_CURVE_TYPE type,           // curve type
    const string     name=NULL       // curve name
)
```

Version for working by Y coordinate (a curve color is set by a user)

```
CCurve* CurveAdd(  
    const double    &y[],           // Y coordinates  
    const uint      clr,           // curve color  
    ENUM_CURVE_TYPE type,         // curve type  
    const string    name=NULL      // curve name  
)
```

Note

Y array indices are used as X coordinates for the curve.

This version uses the X and Y coordinates (a curve color is set by a user)

```
CCurve* CurveAdd(  
    const double    &x[],           // X coordinates  
    const double    &y[],           // Y coordinates  
    const uint      clr,           // curve color  
    ENUM_CURVE_TYPE type,         // curve type  
    const string    name=NULL      // curve name  
)
```

The version for working with CPoint2D dots (curve color is set by a user)

```
CCurve* CurveAdd(  
    const CPoint2D  &points[],      // dot coordinates  
    const uint      clr,           // curve color  
    ENUM_CURVE_TYPE type,         // curve type  
    const string    name=NULL      // curve name  
)
```

Version for working with the pointer to the CurveFunction function (curve color is set by a user)

```
CCurve* CurveAdd(  
    CurveFunction    function,      // pointer to the function  
    const double     from,          // initial value of the argument  
    const double     to,           // final value of the argument  
    const double     step,         // increment by the argument  
    const uint      clr,           // curve color  
    ENUM_CURVE_TYPE type,         // curve type  
    const string    name=NULL      // curve name  
)
```

Parameters*&x[]*

[in] X coordinate.

&y[]

[in] Y coordinate.

&points[]

[in] Coordinates of dots.

function

[in] Pointer to the function.

from

[in] Initial value of the argument.

to

[in] Final value of the argument.

step

[in] Increment by the argument.

type

[in] Curve type.

name=NULL

[in] Curve name.

clr

[in] Curve color.

Return Value

Pointer to the created curve.

CurvePlot

Displays the previously created curve with a specified index.

```
bool CurvePlot(  
    const int index    // index  
)
```

Parameters

index

[in] Curve index

Return Value

true - successful, otherwise - false.

CurvePlotAll

Displays all curves previously added to a chart.

```
bool CurvePlotAll()
```

Return Value

true - successful, otherwise - false.

CurveTotal

Returns the number of curves added to the chart.

```
int CurveTotal()
```

Return Value

Number of curves.

CurveGetByIndex

Gets the curve by a specified index.

```
CCurve* CurveGetByIndex(  
    const int index    // curve index  
)
```

Parameters

index

[in] Curve index.

Return Value

Pointer to the curve with a specified index.

CurveGetByName

Gets a curve by a specified name.

```
CCurve* CurveGetByName(  
    const string name    // curve name  
)
```

Parameters

name

[in] Curve name.

Return Value

Pointer to the first found curve having a specified name.

CurveRemoveByIndex

Remove a curve by a specified index.

```
bool CurveRemoveByIndex(  
    const int index    // curve index  
)
```

Parameters

index

[in] Index of the curve to be removed.

Return Value

true — successful, otherwise — false.

CurveRemoveByName

Remove a curve by a specified name.

```
bool CurveRemoveByName(  
    const string name    // curve name  
)
```

Parameters

name

[in] Name of the curve to be removed.

Return Value

true — successful, otherwise — false.

CurvesTotal

Get the number of curves for the given chart.

```
int CurvesTotal()
```

Return Value

Number of curves.

Note

All curves on the current chart are considered regardless of drawing and visibility style.

MarksToAxisAdd

Add a scale mark (ticks) to the specified chart axis.

```
bool MarksToAxisAdd(  
    const double      &marks[],           // tick coordinates  
    const int         mark_size,          // tick size  
    ENUM_MARK_POSITION position,          // tick location  
    const int         dimension=0         // dimension  
)
```

Parameters

&marks[]

[in] Tick coordinates

mark_size

[in] Tick size

position

[in] Tick location

dimension=0

[in] 0 – adding to X axis,

1 – adding to Y axis

Return Value

true - successful, otherwise - false.

MajorMarkSize (Get method)

Returns the size of the scale's ticks on the coordinate axes.

```
int MajorMarkSize()
```

MajorMarkSize (Set method)

Returns the size of the scale's ticks on the coordinate axes.

```
void MajorMarkSize(  
    const int size // tick size  
)
```

Parameters

size

[in] Tick size in pixels.

FontSet

Sets the current font parameters.

```
bool FontSet(  
    const string name,      // name  
    const int size,         // size  
    const uint flags=0,     // flags  
    const uint angle=0      // angle  
)
```

Parameters

name

[in] Name.

size

[in] Size.

flags=0

[in] Flags.

angle=0

[in] Angle.

Return Value

true - successful, otherwise - false.

FontGet

Gets the current font parameters.

```
void FontGet(  
    string  &name,      // name  
    int     &size,      // size  
    uint    &flags,     // flags  
    uint    &angle      // angle  
)
```

Parameters

&name

[out] Name.

&size

[out] Size.

&flags

[out] Flags.

&angle

[out] Angle.

Attach

The version for getting a graphical resource from the OBJ_BITMAP_LABEL object and binding it to the CGraphic class instance:

```
bool Attach(  
    const long   chart_id,      // chart ID  
    const string objname       // graphical object name  
)
```

The version for creating a graphical resource for the OBJ_BITMAP_LABEL object and binding it to the CGraphic class instance:

```
bool Attach(  
    const long   chart_id,      // chart ID  
    const string objname,       // graphical object name  
    const int    width,         // image width  
    const int    height        // image height  
)
```

Parameters

chart_id

[in] Chart ID.

objname

[in] Name of the graphical object.

width

[in] Image width in the resource.

height

[in] Image height in the resource.

Return Value

true — successful, false — failed to bind the object.

CalculateMaxMinValues

Calculate (re-calculate) minimum and maximum chart values on both axes.

```
void CalculateMaxMinValues ()
```

Height

Get a chart height in pixels.

```
int Height()
```

Return Value

Chart height in pixels.

IndentDown (Get method)

Get a chart indent from the lower border.

```
int IndentDown()
```

Return Value

Indent size in pixels.

IndentDown (Set method)

Set a chart indent from the lower border.

```
void IndentDown(  
    const int down // indent size  
)
```

Parameters

down

[in] Indent size in pixels.

IndentLeft (Get method)

Get a chart indent from the left border.

```
int IndentLeft()
```

Return Value

Indent size in pixels.

IndentLeft (Set method)

Set a chart indent from the left border.

```
void IndentLeft(  
    const int left    // indent size  
)
```

Parameters

left

[in] Indent size in pixels.

IndentRight (Get method)

Get a chart indent from the right border.

```
int IndentRight()
```

Return Value

Indent size in pixels.

IndentRight (Set method)

Set a chart indent from the right border.

```
void IndentRight(  
    const int right // indent size  
)
```

Parameters

right

[in] Indent size in pixels.

IndentUp (Get method)

Get a chart indent from the upper border.

```
int IndentUp()
```

Return Value

Indent size in pixels.

IndentUp (Set method)

Set a chart indent from the upper border.

```
void IndentUp(  
    const int up    // indent size  
)
```

Parameters

up

[in] Indent value in pixels.

Redraw

Redraw the chart.

```
bool Redraw(  
    const bool rescale=false    // flag value  
)
```

Parameters

rescale=false

[in] The flag indicating if a chart should be re-scaled.

Return Value

true - successful, otherwise - false.

ResetParameters

Reset the chart redrawing parameters.

```
void ResetParameters ()
```

ScaleX

Scale the value by X axis.

```
virtual int ScaleX(  
    double x      // value by X axis  
)
```

Parameters

x

[in] Real value by X axis.

Return Value

A value in pixels.

Note

Scale a real value to pixels for displaying on the chart.

ScaleY

Scale the value by Y axis.

```
virtual int ScaleY(  
    double y      // value by Y axis  
)
```

Parameters

y

[in] Real value by Y axis.

Return Value

A value in pixels.

Note

Scale a real value to pixels for displaying on the chart.

SetDefaultParameters

Set the chart parameters to default values.

```
void SetDefaultParameters ()
```

Width

Get the chart width in pixels.

```
int Width()
```

Return Value

Chart width in pixels.

Technical Indicators and Timeseries

This section contains the technical details of the technical indicator and timeseries classes and description of the corresponding components of the standard MQL5 library.

The use of the technical indicator and timeseries classes will save time in developing applications (scripts, Expert Advisors).

The MQL5 Standard Library (in terms of technical indicators and timeseries) is located in the working directory of the terminal in the Include\Indicators folder.

Class/group	Description
Base classes	Group of base and auxiliary classes
Timeseries classes	Group of timeseries classes
Trend Indicators	Group of Trend indicator classes
Oscillators	Group of Oscillator indicator classes
Volume Indicators	Group of Volume indicator classes
Bill Williams Indicators	Group of Bill Williams indicator classes
Custom indicators	Custom indicator class

Base and Auxiliary Technical Indicator and Timeseries Classes

This section contains the technical details of base and auxiliary technical indicator and timeseries classes and description of the corresponding components of the Standard MQL5 library.

Class/group	Description
<u>CSpreadBuffer</u>	Historical spread buffer class
<u>CTimeBuffer</u>	Historical opening prices buffer class
<u>CTickVolumeBuffer</u>	Historical tick volumes buffer class
<u>CRealVolumeBuffer</u>	Historical real volumes buffer class
<u>CDoubleBuffer</u>	Base class of double type data buffer
<u>COpenBuffer</u>	Opening bar prices buffer class
<u>CHighBuffer</u>	High bar prices buffer class
<u>CLowBuffer</u>	Low bar prices buffer class
<u>CCloseBuffer</u>	Closing bar prices buffer class
<u>CIndicatorBuffer</u>	Technical indicator buffer class
<u>CSeries</u>	Base class for access to timeseries data
<u>CPriceSeries</u>	Base class for access to price data
<u>CIndicator</u>	Base class of technical indicator
<u>CLindicators</u>	Technical indicator and timeseries collection

CSpreadBuffer

CSpreadBuffer is a class for simplified access to spreads of the bars in the history.

Description

The CSpreadBuffer class provides a simplified access to spreads of the bars in the history.

Declaration

```
class CSpreadBuffer: public CArrayInt
```

Title

```
#include <Indicators\TimeSeries.mqh>
```

Size

Sets buffer size.

```
void Size(  
    const int size    // size  
)
```

Parameters

size

[in] New buffer size.

SetSymbolPeriod

Sets symbol and period.

```
void SetSymbolPeriod(  
    const string      symbol,      // symbol  
    const ENUM_TIMEFRAMES period    // period  
)
```

Parameters

symbol

[in] New symbol.

period

[in] New period ([ENUM_TIMEFRAMES](#) enumeration).

At

Gets the buffer element.

```
int At(  
    const int index    // index  
    ) const
```

Parameters

index

[in] Index of buffer element.

Return Value

Buffer element with the specified index.

Refresh

Updates the buffer.

```
virtual bool Refresh()
```

Return Value

true - successful, false - cannot update the buffer.

RefreshCurrent

Updates the current (zeroth) element of the buffer.

```
virtual bool RefreshCurrent()
```

Return Value

true - successful, false - cannot update the buffer.

CTimeBuffer

CTimeBuffer is a class for simplified access to opening times of the bars in the history.

Description

The CTimeBuffer class provides a simplified access to opening times of the bars in the history.

Declaration

```
class CTimeBuffer: public CArrayLong
```

Title

```
#include <Indicators\TimeSeries.mqh>
```

Inheritance hierarchy

Size

Sets buffer size.

```
void Size(  
    const int size    // size  
)
```

Parameters

size

[in] New buffer size.

SetSymbolPeriod

Sets symbol and period.

```
void SetSymbolPeriod(  
    const string      symbol,      // symbol  
    const ENUM_TIMEFRAMES period    // period  
)
```

Parameters

symbol

[in] New symbol.

period

[in] New period ([ENUM_TIMEFRAMES](#) enumeration).

At

Gets the buffer element.

```
long At(  
    const int index    // index  
) const
```

Parameters

index

[in] Index of buffer element.

Return Value

Buffer element with the specified index.

Refresh

Updates the buffer.

```
virtual bool Refresh()
```

Return Value

true - successful, false - cannot update the buffer.

RefreshCurrent

Updates the current (zeroth) element of the buffer.

```
virtual bool RefreshCurrent()
```

Return Value

true - successful, false - cannot update the buffer.

CTickVolumeBuffer

CTickVolumeBuffer is a class for simplified access to tick volumes of bars in the history.

Description

The CTickVolumeBuffer class provides a simplified access to tick volumes of bars in the history.

Declaration

```
class CTickVolumeBuffer: public CArrayLong
```

Title

Parameters

symbol

[in] New symbol.

period

[in] New period ([ENUM_TIMEFRAMES](#) enumeration).

At

Gets the buffer element.

```
long At(  
    const int index    // index  
    ) const
```

Parameters

index

[in] Index of buffer element.

Return Value

Buffer element with the specified index.

Refresh

Updates the buffer.

```
virtual bool Refresh()
```

Return Value

true - successful, false - cannot update the buffer.

RefreshCurrent

Updates the current (zeroth) element of the buffer.

```
virtual bool RefreshCurrent()
```

Return Value

true - successful, false - cannot update the buffer.

CRealVolumeBuffer

CRealVolumeBuffer is a class for simplified access to real volumes of bars in the history.

Description

CTickVolumeBuffer class provides a simplified access to real volumes of bars in the history.

symbol

[in] New symbol.

period

[in] New period ([ENUM_TIMEFRAMES](#) enumeration).

At

Gets the buffer element.

```
long At(  
    const int index    // index  
    ) const
```

Parameters

index

[in] Index of buffer element.

Return Value

Buffer element with the specified index.

Refresh

Updates the buffer.

```
virtual bool Refresh()
```

Return Value

true - successful, false - cannot update the buffer.

RefreshCurrent

Updates the current (zeroth) element of the buffer.

```
virtual bool RefreshCurrent()
```

Return Value

true - successful, false - cannot update the buffer.

CDoubleBuffer

CDoubleBuffer is a base class for simplified access to data buffers of double type.

Description

The CDoubleBuffer class provides a simplified access to the data of the buffer of double type.

Sets buffer size.

```
void Size(  
    const int size    // size  
)
```

Parameters

size

[in] New buffer size.

SetSymbolPeriod

Sets symbol and period.

```
void SetSymbolPeriod(  
    const string      symbol,      // symbol  
    const ENUM_TIMEFRAMES period    // period  
)
```

Parameters

symbol

[in] New symbol.

period

[in] New period ([ENUM_TIMEFRAMES](#) enumeration).

At

Gets the buffer element.

```
double At(  
    const int index    // index  
) const
```

Parameters

index

[in] Index of buffer element.

Return Value

Buffer element with the specified index.

Refresh

Updates the buffer.

```
virtual bool Refresh()
```

Return Value

true - successful, false - cannot update the buffer.

RefreshCurrent

Updates the current (zeroth) element of the buffer.

```
virtual bool RefreshCurrent()
```

Return Value

true - successful, false - cannot update the buffer.

COpenBuffer

COpenBuffer is a class for simplified access to open prices of bars in the history.

Description

COpenBuffer class provides a simplified access to open prices of bars in the history.

Declaration

```
class COpenBuffer: public CDoubleBuffer
```

Title

[Size](#), [At](#), [SetSymbolPeriod](#)

Offset

Gets offset of the buffer.

```
int Offset() const
```

Return Value

Buffer offset.

Offset

Sets offset of the buffer.

```
void Offset(  
    const int offset    // offset  
)
```

Parameters

offset

[in] New buffer offset.

Name

Gets the name of the buffer.

```
string Name() const
```

Return Value

Name of the buffer.

Name

Sets the name of the buffer.

```
void Name(  
    const string name    // name  
)
```

Parameters

name

[in] New name of the buffer.

At

Gets buffer element.

```
double At(  
    int index    // index  
) const
```

Parameters

index

[in] Index of buffer element.

Return Value

Buffer element with the specified index.

Refresh

Updates the whole buffer.

```
bool Refresh(  
    const int handle,    // indicator handle  
    const int num        // buffer number  
)
```

Parameters

handle

[in] Handle of the indicator.

num

[in] Buffer index of the indicator.

Return Value

true - successful, false - cannot update the buffer.

RefreshCurrent

Updates the current (zeroth) buffer element.

```
bool RefreshCurrent(  
    const int handle,      // handle of the indicator  
    const int num          // buffer number  
)
```

Parameters

handle

[in] Handle of the indicator.

num

[in] Indicator buffer number.

Return Value

true - successful, false - cannot update the buffer.

CSeries

CSeries is a base class for an access to the timeseries data of the Standard Library.

Description

CSeries class provides the simplified access to all the MQL5 API general functions related to working with the series data for all its descendants (timeseries and indicator classes).

Declaration

```
class CSeries: public CArrayObj
```

Title

```
#include <Indicators\Series.mqh>
```

Inheritance hierarchy

[CObject](#)

[CArray](#)

[CArrayObj](#)

Attributes	
Name	Gets the name of timeseries or indicator
BuffersTotal	Gets the number of buffers of timeseries or indicator
Timeframe	Gets the timeframe flag of timeseries or indicator
Symbol	Gets the symbol of timeseries or indicator
Period	Gets the period of timeseries or indicator
RefreshCurrent	Sets/resets the flag of updating the current data
Data Access	
virtual BufferResize	Sets buffer size of timeseries or indicator
Data Update	
virtual Refresh	Update the data of timeseries or indicator

[PeriodDescription](#)Transforms [ENUM_TIMEFRAMES](#) into a string**Methods inherited from class CObject**Prev, Prev, Next, Next, [Compare](#)**Methods inherited from class CArray**[Step](#), [Step](#), [Total](#), [Available](#), [Max](#), [IsSorted](#), [SortMode](#), [Clear](#), [Sort](#)**Methods inherited from class CArrayObj**[FreeMode](#), [FreeMode](#), [Type](#), [Save](#), [Load](#), [CreateElement](#), [Reserve](#), [Resize](#), [Shutdown](#), [Add](#), [AddArray](#), [Insert](#), [InsertArray](#), [AssignArray](#), [At](#), [Update](#), [Shift](#), [Detach](#), [Delete](#), [DeleteRange](#), [Clear](#), [CompareArray](#), [InsertSort](#), [Search](#), [SearchGreat](#), [SearchLess](#), [SearchGreatOrEqual](#), [SearchLessOrEqual](#), [SearchFirst](#), [SearchLast](#)

Name

Gets the name of timeseries or indicator.

```
string Name() const
```

Return Value

The name of timeseries or indicator.

BuffersTotal

Gets the number of buffers of timeseries or indicator.

```
int BuffersTotal() const
```

Return Value

The number of buffers of timeseries or indicator.

Note

The timeseries has only one buffer.

Timeframe

Gets the timeframe flag of timeseries or indicator.

```
int Timeframe() const
```

Return Value

The timeframe flag of timeseries or indicator.

Note

It is generated as the object visibility flags.

Symbol

Gets the symbol of timeseries or indicator.

```
string Symbol() const
```

Return Value

The symbol of timeseries or indicator.

Period

Gets the period of timeseries or indicator.

```
ENUM_TIMEFRAMES Period() const
```

Return Value

The period (value of [ENUM_TIMEFRAMES](#) enumeration) of timeseries or indicator.

RefreshCurrent

Sets a flag to constantly update the current values of timeseries or indicator.

```
string RefreshCurrent(  
    const bool flag    // value  
)
```

Parameters

flag

[in] New flag.

Return Value

None.

BufferSize

Returns the amount of data available in timeseries buffer or indicator buffer.

```
int BufferSize() const
```

Return Value

Amount of data available in timeseries buffer or indicator buffer.

BufferResize

Sets buffer size of timeseries or indicator.

```
virtual bool BufferResize(  
    const int size    // size  
)
```

Parameters

size

[in] New size of the buffers.

Return Value

true - successful, otherwise - false.

Note

All the timeseries or indicator buffers have the same size.

Refresh

Updates the data of timeseries or indicator.

```
virtual void Refresh(  
    const int flags    // flags  
)
```

Parameters

flags

[in] Timeframes to update (flag).

PeriodDescription

Gets the string representation of the specified [ENUM_TIMEFRAMES](#) enumeration.

```
string PeriodDescription(  
    const int val=0      // value  
)
```

Parameters

val=0

[in] Value to convert.

Return Value

The string representation of the specified [ENUM_TIMEFRAMES](#) enumeration.

Note

If the value is not specified or equal to zero, the timeframe of timeseries or indicator is transformed into a string.

CPriceSeries

CPriceSeries is a base class for access to the price data.

Description

CSeries class provides the simplified access to MQL5 API general functions for working with price data to all its descendants.

Declaration

```
class CPriceSeries: public CSeries
```

Title

```
#include <Indicators\TimeSeries.mqh>
```

Inheritance hierarchy

Methods inherited from class CSeries

[Name](#), [BuffersTotal](#), [BufferSize](#), [Timeframe](#), [Symbol](#), [Period](#), [PeriodDescription](#), [RefreshCurrent](#)

BufferResize

Sets the series buffer size.

```
virtual void BufferResize(  
    const int size    // size  
)
```

Parameters

size

[in] New buffer size.

Return Value

true - successful, otherwise - false.

GetData

Gets the specified series buffer element.

```
double GetData(  
    const int index    // index  
) const
```

Parameters

index

[in] Index of a buffer element.

Return Value

The series buffer element, or [EMPTY_VALUE](#).

Refresh

Updates the timeseries data

```
virtual void Refresh(  
    const int flags=OBJ_ALL_PERIODS    // flags  
)
```

Parameters

flags=OBJ_ALL_PERIODS

[in] Timeframe flags.

MinIndex

Gets the index of minimal value in the specified range.

```
virtual int MinIndex(  
    const int start,      // size  
    const int count       // number  
) const
```

Parameters

start

[in] Search range initial index.

count

[in] Search range size (number of elements).

Return Value

The index of minimal value of a series buffer in the specified range, or -1.

MinValue

Gets the minimal value in the specified range.

```
virtual double MinValue(  
    const int    start,      // size  
    const int    count,      // number  
    int&         index       // reference  
) const
```

Parameters

start

[in] Search range initial index.

count

[in] Search range size (number of elements).

index

[out] Reference to the variable for placing the found element's index value.

Return Value

The minimal value of the series buffer in the specified range, or [EMPTY_VALUE](#).

Note

The index of the found element is stored by index reference.

MaxIndex

Gets the index of maximal value in the specified range.

```
virtual int MaxIndex(  
    const int start,    // index  
    const int count     // number  
) const
```

Parameters

start

[in] Search range initial index.

count

[in] Search range size (number of elements).

Return Value

The index of the maximal value of the series buffer in the specified range, or -1.

MaxValue

Gets the maximal value in the specified range.

```
virtual double MaxValue(  
    const int    start,      // size  
    const int    count,     // amount  
    int&         index       // reference  
) const
```

Parameters

start

[in] Search range initial index.

count

[in] Search range size (number of elements).

index

[out] Reference to the variable for placing the found element's index value.

Return Value

The maximal value of a series buffer in the specified range, or [EMPTY_VALUE](#).

Note

The index of the found element is stored by index reference.

CIndicator

CIndicator is a base class for technical indicator classes of the MQL5 standard library.

Description

The CIndicator class provides the simplified access for all of its descendants to general MQL5 API technical indicator functions.

Declaration

```
class CIndicator: public CSeries
```

Title

```
#include <Indicators\Indicator.mqh>
```

Inheritance hierarchy

[CObject](#)

[CArray](#)

[CArrayObj](#)

[CSeries](#)

CIndicator

Direct descendants

[CiAC](#), [CiAD](#), [CiADX](#), [CiADXWilder](#), [CiAlligator](#), [CiAMA](#), [CiAO](#), [CiATR](#), [CiBands](#), [CiBearsPower](#), [CiBullsPower](#), [CiBWMFI](#), [CiCCI](#), [CiChaikin](#), [CiCustom](#), [CiDEMA](#), [CiDeMarker](#), [CiEnvelopes](#), [CiForce](#), [CiFractals](#), [CiFrAMA](#), [CiGator](#), [CiIchimoku](#), [CiMA](#), [CiMACD](#), [CiMFI](#), [CiMomentum](#), [CiOBV](#), [CiOsMA](#), [CiRSI](#), [CiRVI](#), [CiSAR](#), [CiStdDev](#), [CiStochastic](#), [CiTEMA](#), [CiTriX](#), [CiVIDyA](#), [CiVolumes](#), [CiWPR](#)

Class Methods by Groups

Attributes	
Handle	Gets the indicator's handle.
Status	Gets the status of the indicator.
FullRelease	Sets a flag to release the handle.
Creation	
Create	Creates the indicator
BufferResize	Sets the new buffer sizes
Data Access	
GetData	Copies the data from the indicator buffer
Data Update Methods	
Refresh	Updates the indicator data

Finding Min/Max Values	
Minimum	Gets the index of minimal value in a specified range.
MinValue	Gets the minimal value in a specified range.
Maximum	Gets the index of maximal value in a specified range.
MaxValue	Gets the maximal value in a specified range.
Conversion of Enumerations	
MethodDescription	Converts ENUM_MA_METHOD into a string
PriceDescription	Converts ENUM_APPLIED_PRICE into a string
VolumeDescription	Converts ENUM_APPLIED_VOLUME into a string
Working with chart	
AddToChart	Adds an indicator to the chart
DeleteFromChart	Deletes an indicator from the chart

Methods inherited from class CSeries

[Name](#), [BuffersTotal](#), [BufferSize](#), [Timeframe](#), [Symbol](#), [Period](#), [PeriodDescription](#), [RefreshCurrent](#)

Handle

Gets the indicator's handle.

```
int Handle() const
```

Return Value

Handle of the indicator.

Status

Gets the status of the indicator.

```
string Status() const
```

Return Value

The status of indicator creation.

FullRelease

Sets a flag to release the handle.

```
void FullRelease(  
    const bool flag=true    // flag  
)
```

Parameters

flag

[in] New value of the handle release flag.

Create

Creates the indicator of the specified type with the specified parameters.

```
bool Create(  
    const string      symbol,          // symbol  
    const ENUM_TIMEFRAMES period,      // period  
    const ENUM_INDICATOR type,         // type  
    const int         num_params,      // number of parameters  
    const MqlParam&   params[]        // array of parameters  
)
```

Parameters

symbol

[in] Indicator symbol.

period

[in] Indicator timeframe ([ENUM_TIMEFRAMES](#) enumeration).

type

[in] Indicator type ([ENUM_INDICATOR](#) enumeration).

num_params

[in] Number of indicator's parameters.

params

[in] Reference to the parameters array for the indicator.

Return Value

true - successful, false - cannot create the indicator.

BufferResize

Sets the sizes of the indicator buffers.

```
virtual bool BufferResize(  
    const int size    // size  
)
```

Parameters

size

[in] New buffer size.

Return Value

true - successful, otherwise - false.

Note

All the indicator buffers have the same size.

BarsCalculated

Returns the amount of calculated data for the indicator.

```
int BarsCalculated() const;
```

Return Value

Returns the amount of calculated data in the indicator buffer, or -1 in the case of error (data is not calculated yet).

GetData

Gets the specified element of the specified buffer of the indicator. [Refresh\(\)](#) should be called for working with recent data before using the method.

```
double  GetData (
    const int  buffer_num,      // buffer number
    const int  index           // index
) const
```

Parameters

buffer_num

[in] Indicator buffer number.

index

[in] Indicator buffer element index.

Return Value

value - success, [EMPTY_VALUE](#) - cannot receive the data.

GetData

Gets the data from the indicator's buffer by starting position and number.

```
int  GetData (
    const int      start_pos,      // position
    const int      count,          // number
    const int      buffer_num,     // buffer number
    double&        buffer[]        // array
) const
```

Parameters

start_pos

[in] Starting position of the indicator buffer.

count

[in] Number of indicator buffer elements.

buffer_num

[in] Number of the indicator buffer.

buffer

[in] Reference to the array for storing data.

Return Value

Number of the indicator values received from the specified indicator buffer - success, otherwise -1.

GetData

Gets the data from the indicator buffer by start time and number.

```
int  GetData(
    const datetime  start_time,    // starting time
    const int       count,         // amount
    const int       buffer_num,    // buffer number
    double&         buffer[]       // array
) const
```

Parameters

start_time

[in] Indicator buffer element starting time.

count

[in] Number of indicator buffer elements.

buffer_num

[in] Number of the indicator buffer.

buffer

[in] Reference to the array for storing data.

Return Value

Number of the indicator values received from the specified buffer, otherwise -1.

GetData

Gets the data from the indicator buffer by start and end time.

```
int  GetData(
    const datetime  start_time,    // start time
    const datetime  stop_time,     // end time
    const int       buffer_num,    // number of buffer
    double&         buffer[]       // array
) const
```

Parameters

start_time

[in] Indicator buffer initial element time.

stop_time

[in] Indicator buffer end element time.

buffer_num

[in] Number of the indicator buffer.

buffer

[in] Reference to the array for storing data.

Return Value

Number of the indicator values received from the specified buffer - success, otherwise -1.

Refresh

Updates the indicator data. It is recommended calling the method before using [GetData\(\)](#).

```
virtual void Refresh(  
    int flags=OBJ_ALL_PERIODS    // flags  
)
```

Parameters

flags=OBJ_ALL_PERIODS

[in] Timeframe update flags.

Minimum

Returns the index of minimal element of the specified buffer in a specified range.

```
int Minimum(  
    const int  buffer_num,      // buffer number  
    const int  start,          // starting index  
    const int  count           // number  
) const
```

Parameters

buffer_num

[in] Buffer number to search the value in.

start

[in] Search range initial index.

count

[in] Search range size (number of elements).

Return Value

Index of the minimal element of the specified buffer in a specified range.

MinValue

Returns the value of minimal element of the specified buffer in a specified range.

```
double MinValue(  
    const int    buffer_num,      // buffer number  
    const int    start,           // starting index  
    const int    count,           // number  
    int&         index            // reference  
) const
```

Parameters

buffer_num

[in] Buffer number to search the value in.

start

[in] Search range initial index.

count

[in] Search range size (number of elements).

index

[out] Reference to the variable for storing the found element index value.

Return Value

The value of the minimal element of the specified buffer in a specified range.

Note

The index of the found element is stored by index reference.

Maximum

Returns the index of maximal element of the specified buffer in a specified range.

```
int Maximum(  
    const int  buffer_num,      // buffer number  
    const int  start,          // starting index  
    const int  count           // number  
) const
```

Parameters

buffer_num

[in] Buffer number to search the value in.

start

[in] Search range initial index.

count

[in] Search range size (number of elements).

Return Value

Index of the maximal element of the specified buffer in a specified range.

MaxValue

Returns the value of maximal element of the specified buffer in a specified range.

```
double MaxValue(  
    const int    buffer_num,      // buffer number  
    const int    start,           // starting index  
    const int    count,           // number  
    int&         index            // reference  
) const
```

Parameters

buffer_num

[in] Buffer number to search the value in.

start

[in] Search range initial index.

count

[in] Search range size (number of elements).

index

[out] Reference to the variable for storing the found element index value.

Return Value

The value of the maximal element of the specified buffer in a specified range.

Note

The index of maximal buffer element is stored by index reference.

MethodDescription

Converts [ENUM_MA_METHOD](#) enumeration value to a string.

```
string MethodDescription(  
    const int val    // value  
) const
```

Parameters

val

[in] Conversion value.

Return Value

The string corresponding to [ENUM_MA_METHOD](#) enumeration value.

PriceDescription

Converts [ENUM_APPLIED_PRICE](#) enumeration value to a string.

```
string PriceDescription(  
    const int val    // value  
) const
```

Parameters

val

[in] Conversion value.

Return Value

The string corresponding to [ENUM_APPLIED_PRICE](#) enumeration value.

VolumeDescription

Converts [ENUM_APPLIED_VOLUME](#) enumeration value to a string.

```
string VolumeDescription(  
    const int val    // value  
) const
```

Parameters

val

[in] Conversion value.

Return Value

The string corresponding to [ENUM_APPLIED_VOLUME](#) enumeration value.

AddToChart

Adds the indicator to the chart.

```
bool AddToChart(  
    const long chart,      // chart ID  
    const int subwin       // subwindow index  
)
```

Parameters

chart

[in] Chart ID.

subwin

[in] Chart subwindow index.

Return Value

true - successful, false - cannot add the indicator to the chart.

DeleteFromChart

Deletes the indicator from the chart.

```
bool DeleteFromChart(  
    const long chart,      // chart ID  
    const int subwin       // subwindow index  
)
```

Parameters

chart

[in] Chart ID.

subwin

[in] Chart subwindow index.

Return Value

true - successful, false - cannot remove the indicator from the chart.

Indicators

The Indicators is a class for collecting instances of timeseries and technical indicators classes.

Description

Indicators class provides creation of the technical indicators class instances, their storage and management (data synchronization, handle and memory management).

Declaration

```
class CIndicators: public CArrayObj
```

Title

```
#include <Indicators\Indicators.mqh>
```

Class Methods by Groups

Create	
Create	Creates an indicator
Data Update	
Refresh	Updates indicator data

Create

Creates the indicator of the specified type with the specified parameters.

```
CIndicator* Create(  
    const string      symbol,      // symbol name  
    const ENUM_TIMEFRAMES period,    // period  
    const ENUM_INDICATOR type,      // type  
    const int         count,      // number of parameters  
    const MqlParam&   params      // parameters array  
)
```

Parameters

symbol

[in] Indicator symbol name.

period

[in] Indicator timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

type

[in] Indicator type ([ENUM_INDICATOR](#) enumeration value).

count

[in] Number of parameters for the indicator.

params

[in] Reference to the parameters array for the indicator.

Return Value

Reference to the created indicator - successful, [NULL](#) - cannot create the indicator.

Refresh

Updates data for all timeseries and technical indicators in the collection.

```
int Refresh()
```

Return Value

Updated timeframe flags (formed as object visibility flags).

Timeseries classes

This group of chapters contains technical details of timeseries classes of the MQL5 Standard Library and descriptions of all its key components.

Class	Description
<u>CiSpread</u>	Provides an access to spread historical data
<u>CiTime</u>	Provides an access to open times of the bars in the history
<u>CiTickVolume</u>	Provides an access to tick volumes of the bars in the history
<u>CiRealVolume</u>	Provides an access to real volumes of the bars in the history
<u>CiOpen</u>	Provides an access to open prices of the bars in the history
<u>CiHigh</u>	Provides an access to high prices of the bars in the history
<u>CiLow</u>	Provides an access to low prices of the bars in the history
<u>CiClose</u>	Provides an access to close prices of the bars in the history

CiSpread

CiSpread is a class designed for access to spreads of the bars in the history.

Description

CiSpread class provides an access to spread historical data.

Declaration

```
class CiSpread: public CSeries
```

Title

```
#include <Indicators\TimeSeries.mqh>
```

Inheritance hierarchy

Methods inherited from class CSeries

[Name](#), [BuffersTotal](#), [BufferSize](#), [Timeframe](#), [Symbol](#), [Period](#), [PeriodDescription](#), [RefreshCurrent](#)

Create

Creates a timeseries with the specified parameters for access to the spreads history.

```
bool Create(  
    string      symbol,      // symbol  
    ENUM_TIMEFRAMES period    // period  
)
```

Parameters

symbol

[in] Timeseries symbol.

period

[in] Timeseries timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

Return Value

true - successful, false - cannot create the timeseries.

BufferResize

Sets size of the buffer series.

```
virtual void BufferResize(  
    int size    // size  
)
```

Parameters

size

[in] New buffer size.

GetData

Gets the specified element of timeseries buffer.

```
int  GetData(  
    int  index      // index  
    ) const
```

Parameters

index

[in] Index of the buffer element.

Return Value

The timeseries buffer element, or 0.

GetData

Gets the element of timeseries by starting position and number of elements.

```
int  GetData(  
    int  start_pos,    // position  
    int  count,        // number  
    int& buffer        // array  
    ) const
```

Parameters

start_pos

[in] Starting position of a timeseries buffer.

count

[in] Number of timeseries buffer elements.

buffer

[in] Reference to the array for storing the data.

Return Value

>=0 - successful, -1 - cannot receive the data.

GetData

Gets data from a timeseries buffer by initial time and number.

```
int  GetData(  
    datetime start_time,    // starting time  
    int      count,        // number  
    int&     buffer        // array  
    ) const
```

Parameters

start_time

[in] Time of the timeseries buffer's initial element.

count

[in] Number of timeseries buffer elements.

buffer

[in] Reference to the array for storing data.

Return Value

>=0 - successful, -1 - cannot receive data.

GetData

Gets the data from a timeseries buffer by start and stop times.

```
int  GetData(  
    datetime  start_time,    // starting time  
    datetime  stop_time,     // stop time  
    int&      buffer         // array  
) const
```

Parameters

start_time

[in] Starting time of a timeseries buffer element.

stop_time

[in] Stop time of a timeseries buffer element.

buffer

[in] Reference to the array for storing data.

Return Value

>=0 - successful, -1 - cannot receive the data.

Refresh

Updates the data of timeseries.

```
virtual void Refresh(  
    int flags    // flags  
)
```

Parameters

flags

[in] Timeframe flags.

CiTime

CiTime is a class designed for access to open times of the bars in the history.

Description

CiTime class provides an access to open times of the bars in the history.

Declaration

```
class CiTime: public CSeries
```

Title

```
#include <Indicators\TimeSeries.mqh>

[Name](#), [BuffersTotal](#), [BufferSize](#), [Timeframe](#), [Symbol](#), [Period](#), [PeriodDescription](#), [RefreshCurrent](#)

Create

Creates a timeseries with the specified parameters for access to the opening times of the bars in the history.

```
bool Create(  
    string      symbol,      // symbol  
    ENUM_TIMEFRAMES period    // period  
)
```

Parameters

symbol

[in] Timeseries symbol.

period

[in] Timeseries timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

Return Value

true - successful, false - cannot create timeseries.

BufferResize

Sets series buffer sizes.

```
virtual void BufferResize(  
    int size    // size  
)
```

Parameters

size

[in] New buffer size.

GetData

Gets the specified element of a timeseries buffer.

```
datetime GetData(  
    int index      // index  
    ) const
```

Parameters

index

[in] Index of the buffer element.

Return Value

The timeseries buffer element, or 0.

GetData

Gets the data from a timeseries buffer by starting position and number.

```
int GetData(  
    int start_pos,    // position  
    int count,        // number  
    long& buffer      // array  
    ) const
```

Parameters

start_pos

[in] Starting position of timeseries.

count

[in] Number of timeseries buffer elements.

buffer

[in] Reference to the array for storing data.

Return Value

>=0 - successful, -1 - cannot receive data.

GetData

Gets the data from timeseries buffer by starting time and number.

```
int GetData(  
    datetime start_time,    // starting time  
    int count,              // number  
    long& buffer            // array  
    ) const
```

Parameters

start_time

[in] Time of a timeseries buffer initial element.

count

[in] Number of timeseries buffer elements.

buffer

[in] Reference to the array for storing data.

Return Value

>=0 - successful, -1 - cannot receive data.

GetData

Gets the data from a timeseries buffer by starting and stop times.

```
int  GetData(  
    datetime  start_time,    // starting time  
    datetime  stop_time,     // stop time  
    long&     buffer         // array  
) const
```

Parameters

start_time

[in] Time of a timeseries buffer initial element.

stop_time

[in] Time of a timeseries buffer end element.

buffer

[in] Reference to the array for storing data

Return Value

>=0 - successful, -1 - cannot receive data.

Refresh

Updates the data of timeseries.

```
virtual void Refresh(  
    int flags    // flags  
)
```

Parameters

flags

[in] Timeframe flags.

CiTickVolume

CiTickVolume is a class designed for access to tick volumes of the bars in the history.

Description

CiTickVolume class provides an access to tick volumes of the bars in the history.

Declaration

```
class CiTickVolume: public CSeries
```

Title

```

Methods inherited from class CSeries

[Name](#), [BuffersTotal](#), [BufferSize](#), [Timeframe](#), [Symbol](#), [Period](#), [PeriodDescription](#), [RefreshCurrent](#)

Create

Creates a timeseries with the specified parameters for access to the tick volumes of the bars in the history.

```
bool Create(  
    string      symbol,      // symbol  
    ENUM_TIMEFRAMES period  // period  
)
```

Parameters

symbol

[in] Timeseries symbol.

period

[in] Timeseries timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

Return Value

true - successful, false - cannot create a timeseries.

BufferResize

Sets size of the series buffer.

```
virtual void BufferResize(  
    int size    // size  
)
```

Parameters

size

[in] New buffer size.

GetData

Gets the specified timeseries buffer element.

```
long  GetData(  
    int  index      // index  
    ) const
```

Parameters

index

[in] Index of the buffer element.

Return Value

The timeseries buffer element, or 0.

GetData

Gets the data from the timeseries buffer by starting position and number.

```
int  GetData(  
    int  start_pos,    // position  
    int  count,        // number  
    long& buffer       // array  
    ) const
```

Parameters

start_pos

[in] Starting position of a timeseries buffer.

count

[in] Number of timeseries buffer elements.

buffer

[in] Reference to the array for storing the data.

Return Value

>=0 - successful, -1 - cannot receive data.

GetData

Gets the data from a timeseries buffer by starting time and number.

```
int  GetData(  
    datetime start_time, // starting time  
    int      count,      // number  
    long&    buffer      // array  
    ) const
```

Parameters

start_time

[in] Time of the timeseries buffer initial element.

count

[in] Number of timeseries buffer elements.

buffer

[in] Reference to the array for storing data.

Return Value

>=0 - successful, -1 - cannot receive data.

GetData

Gets the data from a timeseries buffer by starting and stop times.

```
int  GetData(  
    datetime  start_time,    // starting time  
    datetime  stop_time,     // stop time  
    long&     buffer         // array  
) const
```

Parameters

start_time

[in] Time of the timeseries buffer initial element.

stop_time

[in] Time of the timeseries buffer end element.

buffer

[in] Reference to the array for storing data

Return Value

>=0 - successful, -1 - cannot receive data.

Refresh

Updates the data of timeseries.

```
virtual void Refresh(  
    int flags    // flags  
)
```

Parameters

flags

[in] Timeframe flags.

CiRealVolume

CiRealVolume is a class designed for access to real volumes of the bars in the history.

Description

CiRealVolume class provides an access to real volumes of the bars in the history.

Declaration

```
class CiRealVolume: public CSeries
```

Title

```
#include <Indicators\TimeSeries.mqh>
```

Inheritance hierarchy

Methods inherited from class CSeries

[Name](#), [BuffersTotal](#), [BufferSize](#), [Timeframe](#), [Symbol](#), [Period](#), [PeriodDescription](#), [RefreshCurrent](#)

Create

Creates a timeseries with the specified parameters for access to the real volumes of the bars in the history.

```
bool Create(  
    string      symbol,      // symbol  
    ENUM_TIMEFRAMES period    // period  
)
```

Parameters

symbol

[in] Timeseries symbol.

period

[in] Timeseries timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

Return Value

true - successful, false - cannot create a timeseries.

BufferResize

Sets a series buffer size.

```
virtual void BufferResize(  
    int size    // size  
)
```

Parameters

size

[in] New buffer size.

GetData

Gets the specified series buffer element.

```
datetime GetData(  
    int index      // index  
    ) const
```

Parameters

index

[in] Buffer element index.

Return Value

Series buffer element, or 0.

GetData

Gets the data from timeseries buffer by starting position and number.

```
int GetData(  
    int start_pos,    // position  
    int count,        // number  
    long& buffer      // array  
    ) const
```

Parameters

start_pos

[in] Starting position of timeseries buffer.

count

[in] Number of timeseries buffer elements.

buffer

[in] Reference to the data storage array.

Return Value

>=0 - successful, -1 - cannot receive data.

GetData

Gets the data from timeseries buffer by starting time and number.

```
int GetData(  
    datetime start_time,    // starting time  
    int count,              // number  
    long& buffer            // array  
    ) const
```

Parameters

start_time

[in] Time of the timeseries buffer initial element.

count

[in] Number of timeseries buffer elements.

buffer

[in] Reference to the data storage array.

Return Value

>=0 - successful, -1 - cannot receive data.

GetData

Gets the element of timeseries by starting and stop times.

```
int  GetData(  
    datetime  start_time,    // starting time  
    datetime  stop_time,     // stop time  
    long&     buffer         // target array  
) const
```

Parameters

start_time

[in] Starting time.

stop_time

[in] Stop time.

buffer

[in] Reference to the target array for data

Return Value

>=0 if successful, -1 in the case of error.

Refresh

Updates the data of timeseries.

```
virtual void Refresh(  
    int flags    // flags  
)
```

Parameters

flags

[in] Timeframe flags.

CiOpen

CiOpen is a class designed for access to open prices of the bars in the history.

Description

CiOpen class provides an access to open prices of the bars in the history.

Declaration

Create

Creates a timeseries with the specified parameters for access to the open prices of the bars in the history.

```
bool Create(  
    string      symbol,      // symbol  
    ENUM_TIMEFRAMES period    // period  
)
```

Parameters

symbol

[in] Timeseries symbol.

period

[in] Timeseries timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

Return Value

true - successful, false - cannot create a timeseries.

GetData

Gets the element of timeseries by starting position and number.

```
int  GetData(  
    int    start_pos,      // starting position  
    int    count,         // number  
    double& buffer        // array  
) const
```

Parameters

start_pos

[in] Starting position of timeseries buffer.

count

[in] Number of timeseries buffer elements.

buffer

[in] Reference to the data storage array.

Return Value

>=0 - successful, -1 - cannot receive data.

GetData

Gets data from the timeseries buffer by starting time and number.

```
int  GetData(  
    datetime start_time,   // starting time  
    int      count,       // number  
    double&  buffer       // array  
) const
```

Parameters

start_time

[in] Time of a timeseries buffer initial element.

count

[in] Number of timeseries buffer elements.

buffer

[in] Reference to the data storage array.

Return Value

>=0 - successful, -1 - cannot receive data.

GetData

Gets the data from the timeseries buffer by starting and stop times.

```
int  GetData(  
    datetime  start_time,      // starting time  
    datetime  stop_time,       // stop time  
    double&    buffer          // array  
) const
```

Parameters

start_time

[in] Time of a timeseries buffer initial element.

stop_time

[in] Time of a timeseries buffer last element.

buffer

[in] Reference to the data storage array.

Return Value

>=0 - successful, -1 - cannot receive data.

CiHigh

CiHigh is a class designed for access to high prices of the bars in the history.

Description

CiHigh class provides an access to high prices of the bars in the history.

Create

Creates a timeseries with the specified parameters for access to the high prices of the bars in the history.

```
bool Create(  
    string      symbol,      // symbol  
    ENUM_TIMEFRAMES period    // period  
)
```

Parameters

symbol

[in] Timeseries symbol.

period

[in] Timeseries timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

Return Value

true - successful, false - cannot create a timeseries.

GetData

Gets data from the timeseries buffer by starting position and number.

```
int  GetData(  
    int    start_pos,      // position  
    int    count,         // number  
    double& buffer        // array  
) const
```

Parameters

start_pos

[in] Starting position of a timeseries buffer.

count

[in] Number of timeseries buffer elements.

buffer

[in] Reference to the data storage array.

Return Value

>=0 - successful, -1 - cannot receive data.

GetData

Gets data from the timeseries buffer by starting time and number.

```
int  GetData(  
    datetime start_time,   // starting time  
    int      count,       // number  
    double&  buffer       // array  
) const
```

Parameters

start_time

[in] Time of a timeseries buffer initial element.

count

[in] Number of timeseries buffer elements.

buffer

[in] Reference to the data storage array.

Return Value

>=0 - successful, -1 - cannot receive data.

GetData

Gets data from the timeseries buffer by starting and stop times.

```
int  GetData(  
    datetime  start_time,      // starting time  
    datetime  stop_time,       // stop time  
    double&   buffer           // array  
) const
```

Parameters

start_time

[in] Time of a timeseries buffer initial element.

stop_time

[in] Time of a timeseries buffer last element.

buffer

[in] Reference to the data storage array.

Return Value

>=0 - successful, -1 - cannot receive data.

CiLow

CiLow is a class designed for access to low prices of the bars in the history.

Description

CiLow class provides an access to low prices of the bars in the history.

Declaration

Create

Creates a timeseries with the specified parameters for access to the low prices of the bars in the history.

```
bool Create(  
    string      symbol,      // symbol  
    ENUM_TIMEFRAMES period    // period  
)
```

Parameters

symbol

[in] Timeseries symbol.

period

[in] Timeseries timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

Return Value

true - successful, false - cannot create the timeseries.

GetData

Gets the element of timeseries by starting position and number of elements.

```
int  GetData(  
    int    start_pos,      // position  
    int    count,         // number  
    double& buffer        // array  
) const
```

Parameters

start_pos

[in] Starting position of a timeseries buffer.

count

[in] Number of timeseries buffer elements.

buffer

[in] Reference to the data storage array.

Return Value

>=0 - successful, -1 - cannot receive data.

GetData

Gets the data from a timeseries buffer by starting time and number.

```
int  GetData(  
    datetime start_time,   // starting time  
    int      count,        // number  
    double&  buffer        // array  
) const
```

Parameters

start_time

[in] Time of a timeseries buffer initial element.

count

[in] Number of timeseries buffer elements.

buffer

[in] Reference to the data storage array.

Return Value

>=0 - successful, -1 - cannot receive data.

GetData

Gets data from the timeseries buffer by starting and stop times.

```
int  GetData(  
    datetime  start_time,      // starting time  
    datetime  stop_time,       // stop time  
    double&   buffer           // array  
) const
```

Parameters

start_time

[in] Time of a timeseries buffer initial element.

stop_time

[in] Time of a timeseries buffer last element.

buffer

[in] Reference to the data storage array

Return Value

>=0 - successful, -1 - cannot receive data.

CiClose

CiClose is a class designed for access to close prices of the bars in the history.

Description

CiClose class provides an access to close prices of the bars in the history.

Create

Creates a timeseries with the specified parameters for access to the closing prices of the bars in the history.

```
bool Create(  
    string      symbol,      // symbol  
    ENUM_TIMEFRAMES period    // period  
)
```

Parameters

symbol

[in] Timeseries symbol.

period

[in] Timeseries timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

Return Value

true - successful, false - cannot create the timeseries.

GetData

Gets data from a timeseries buffer by starting position and number.

```
int  GetData(  
    int    start_pos,      // position  
    int    count,         // number  
    double& buffer        // array  
) const
```

Parameters

start_pos

[in] Starting position of a timeseries buffer.

count

[in] Number of timeseries buffer elements.

buffer

[in] Reference to the data storage array.

Return Value

>=0 - successful, -1 - cannot receive data.

GetData

Gets data from a timeseries buffer by starting time and number.

```
int  GetData(  
    datetime start_time,   // starting time  
    int      count,        // number  
    double&  buffer        // array  
) const
```

Parameters

start_time

[in] Time of a timeseries buffer initial element.

count

[in] Number of a timeseries buffer element.

buffer

[in] Reference to the data storage array.

Return Value

>=0 - successful, -1 - cannot receive data.

GetData

Gets data from a timeseries buffer by starting and stop times.

```
int  GetData(  
    datetime  start_time,      // starting time  
    datetime  stop_time,       // stop time  
    double&    buffer          // array  
) const
```

Parameters

start_time

[in] Time of a timeseries buffer initial element.

stop_time

[in] Time of a timeseries buffer last element.

buffer

[in] Reference to the data storage array.

Return Value

>=0 - successful, -1 - cannot receive data.

Main and Auxiliary Classes of Technical Indicators and Timeseries

This group of chapters contains technical details of the main and auxiliary classes of technical indicators and timeseries, as well as descriptions of the appropriate components of the MQL5 Standard Library.

Class/group	Description
<u>CiADX</u>	Average Directional Index
<u>CiADXWilder</u>	Average Directional Index by Welles Wilder
<u>CiBands</u>	Bollinger Bands®
<u>CiEnvelopes</u>	Envelopes
<u>CiIchimoku</u>	Ichimoku Kinko Hyo
<u>CiMA</u>	Moving Average
<u>CiSAR</u>	Parabolic Stop And Reverse System
<u>CiStdDev</u>	Standard Deviation
<u>CiDEMA</u>	Double Exponential Moving Average
<u>CiTEMA</u>	Triple Exponential Moving Average
<u>CiFrAMA</u>	Fractal Adaptive Moving Average
<u>CiAMA</u>	Adaptive Moving Average
<u>CiVIDyA</u>	Variable Index Dynamic Average

CiADX

CiADX is a class intended for using the Average Directional Index technical indicator.

Description

CiADX class provides the creation, configuration, and access to the data of the Average Directional Index indicator.

Declaration

```
class CiADX: public CIndicator
```

Title

```
#include <Indicators\Trend.mqh>
```

MaPeriod

Returns the averaging period.

```
int MaPeriod() const
```

Return Value

Returns the averaging period, defined at the indicator creation.

Create

Creates the indicator with specified parameters. Use [Refresh\(\)](#) and [GetData\(\)](#) to update and get the indicator values.

```
bool Create(  
    string          symbol,          // symbol  
    ENUM_TIMEFRAMES period,          // period  
    int             ma_period        // averaging period  
)
```

Parameters

symbol

[in] Symbol.

period

[in] Timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

ma_period

[in] Averaging period.

Return Value

true - successful, false - cannot create the indicator.

Main

Returns the buffer element of the main line by the specified index.

```
double Main(  
    int index    // index  
)
```

Parameters

index

[in] Main line buffer element index.

Return Value

Main line buffer element by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Plus

Returns the buffer element of the +DI line by the specified index.

```
double Plus(  
    int index    // index  
)
```

Parameters

index

[in] +DI line buffer element index.

Return Value

The buffer element of the +DI line by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Minus

Returns the buffer element of the -DI line by the specified index.

```
double Minus (  
    int index    // index  
)
```

Parameters

index

[in] -DI line buffer element index.

Return Value

The buffer element of the -DI line by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type ([IND_ADX](#) for CiADX).

CiADXWilder

CiADXWilder is a class intended for using the technical indicator Average Directional Index by Welles Wilder.

Description

CiADXWilder class provides the creation, configuration, and access to the data of the Average Directional Index by Welles Wilder.

Declaration

Creates the indicator with specified parameters. Use [Refresh\(\)](#) and [GetData\(\)](#) to update and get the indicator values.

```
bool Create(  
    string          symbol,          // symbol  
    ENUM_TIMEFRAMES period,          // period  
    int             ma_period        // averaging period  
)
```

Parameters

symbol

[in] Symbol.

period

[in] Timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

ma_period

[in] Averaging period.

Return Value

true - successful, false - cannot create the indicator.

Main

Returns the buffer element of the main line by the specified index.

```
double Main(  
    int index    // index  
)
```

Parameters

index

[in] Main line buffer element index.

Return Value

Main line buffer element by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Plus

Returns the buffer element of the +DI line by the specified index.

```
double Plus(  
    int index    // index  
)
```

Parameters

index

[in] +DI line buffer element index.

Return Value

The buffer element of the +DI line by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Minus

Returns the buffer element of the -DI line by the specified index.

```
double Minus (  
    int index    // index  
)
```

Parameters

index

[in] -DI line buffer element index.

Return Value

The buffer element of the -DI line by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type ([IND_ADXW](#) for CiADWWilder).

CiBands

CiBands is a class intended for using the Bollinger Bands® technical indicator.

Description

CiBands class provides the creation, configuration, and access to the data of the Bollinger Bands indicator.

Declaration

```
class CiBands: public CIndicator
```

Title

```
#include <Indicators\Trend.mqh>
```

MaPeriod

Returns the averaging period.

```
int MaPeriod() const
```

Return Value

Returns the averaging period, defined at the indicator creation.

MaShift

Returns the horizontal shift.

```
int MaShift() const
```

Return Value

Returns the horizontal shift value, defined at the indicator creation.

Deviation

Returns the deviation.

```
double Deviation() const
```

Return Value

Returns the deviation, defined at the indicator creation.

Applied

Returns the price type or handle to apply.

```
int Applied() const
```

Return Value

Price type or handle to apply, defined at the indicator creation.

Create

Creates the indicator with specified parameters. Use [Refresh\(\)](#) and [GetData\(\)](#) to update and get the indicator values.

```
bool Create(  
    string          symbol,          // symbol  
    ENUM_TIMEFRAMES period,          // period  
    int             ma_period,        // averaging period  
    int             ma_shift,         // shift  
    double          deviation,        // deviation  
    int             applied           // applied price, handle  
)
```

Parameters

symbol

[in] Symbol.

period

[in] Timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

ma_period

[in] Averaging period.

ma_shift

[in] Horizontal shift of the indicator.

deviation

[in] Deviation.

applied

[in] Price type or handle to apply.

Return Value

true - successful, false - cannot create the indicator.

Base

Returns the buffer element of the base line by the specified index.

```
double Base(  
    int index    // index  
)
```

Parameters

index

[in] Base line buffer element index.

Return Value

The buffer element of the base line by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Upper

Returns the buffer element of the upper line by the specified index.

```
double Upper (  
    int index    // index  
)
```

Parameters

index

[in] Upper line buffer element index.

Return Value

The buffer element of the upper line of the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Lower

Returns the buffer element of the lower line by the specified index.

```
double Lower (  
    int index    // index  
)
```

Parameters

index

[in] Lower line buffer element index.

Return Value

The buffer element of the lower line by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type ([IND_BANDS](#) for CiBands).

CiEnvelopes

CiEnvelopes is a class intended for using the Envelopes technical indicator.

Description

CiEnvelopes class provides the creation, configuration, and access to the data of the Envelopes indicator.

MaPeriod

Returns the averaging period.

```
int MaPeriod() const
```

Return Value

Returns the averaging period, defined at the indicator creation.

MaShift

Returns the horizontal shift of the indicator.

```
int MaShift() const
```

Return Value

Returns the horizontal shift value, defined at the indicator creation.

MaMethod

Returns the averaging method.

```
ENUM_MA_METHOD MaMethod() const
```

Return Value

Returns the averaging method, defined at the indicator creation ([ENUM_MA_METHOD](#) enumeration value).

Deviation

Returns the value of deviation.

```
double Deviation() const
```

Return Value

Returns the value of deviation, defined at the indicator creation.

Applied

Returns the price type or handle to apply.

```
int Applied() const
```

Return Value

Price type or handle to apply, defined at the indicator creation.

Create

Creates the indicator with specified parameters. Use [Refresh\(\)](#) and [GetData\(\)](#) to update and get the indicator values.

```
bool Create(  
    string          symbol,          // symbol  
    ENUM_TIMEFRAMES period,          // period  
    int             ma_period,       // averaging period  
    int             ma_shift,        // shift  
    ENUM_MA_METHOD  ma_method,       // averaging method  
    int             applied,         // price type, handle  
    double          deviation        // deviation  
)
```

Parameters

symbol

[in] Symbol.

period

[in] Timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

ma_period

[in] Averaging period.

ma_shift

[in] Price axis shift.

ma_method

[in] Averaging method ([ENUM_MA_METHOD](#) enumeration value).

applied

[in] Object (price type or handle) to apply.

deviation

[in] Deviation.

Return Value

true - successful, false - cannot create the indicator.

Upper

Returns the buffer element of the upper line by the specified index.

```
double Upper (  
    int index    // index  
)
```

Parameters

index

[in] Upper line buffer element index.

Return Value

The buffer element of the upper line by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Lower

Returns the buffer element of the lower line by the specified index.

```
double Lower (  
    int index    // index  
)
```

Parameters

index

[in] Lower line buffer element index.

Return Value

The buffer element of the lower line by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type ([IND_ENVELOPES](#) for CiEnvelopes).

Cilchimoku

Cilchimoku is a class intended for using the Ichimoku Kinko Hyo technical indicator.

Description

Cilchimoku class provides the creation, setup, and access to the data of the Ichimoku Kinko Hyo indicator.

TenkanSenPeriod

Returns the TenkanSen period.

```
int TenkanSenPeriod() const
```

Return Value

Returns the TenkanSen period, defined at the indicator creation.

KijunSenPeriod

Returns the KijunSen period.

```
int KijunSenPeriod() const
```

Return Value

Returns the KijunSen period, defined at the indicator creation.

SenkouSpanBPeriod

Returns the SenkouSpanB period.

```
int SenkouSpanBPeriod() const
```

Return Value

Returns the SenkouSpanB period, defined at the indicator creation.

Create

Creates the indicator with specified parameters. Use [Refresh\(\)](#) and [GetData\(\)](#) to update and get the indicator values.

```
bool Create(  
    string          symbol,           // symbol  
    ENUM_TIMEFRAMES period,          // period  
    int             tenkan_sen,       // period of TenkanSen  
    int             kijun_sen,        // period of KijunSen  
    int             senkou_span_b    // period of SenkouSpanB  
)
```

Parameters

symbol

[in] Symbol.

period

[in] Timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

tenkan_sen

[in] Period of TenkanSen.

kijun_sen

[in] Period of KijunSen.

senkou_span_b

[in] Period of SenkouSpanB.

Return Value

true - successful, false - cannot create the indicator.

TenkanSen

Returns the buffer element of the TenkanSen line by the specified index.

```
double TenkanSen(  
    int index    // index  
)
```

Parameters

index

[in] TenkanSen line buffer element index.

Return Value

The buffer element of the TenkanSen line by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

KijunSen

Returns the buffer element of the KijunSen line by the specified index.

```
double KijunSen(  
    int index    // index  
)
```

Parameters

index

[in] KijunSen line buffer element index.

Return Value

The buffer element of the KijunSen line of the specified index, or [EMPTY_VALUE](#) if there is no correct data.

SenkouSpanA

Returns the buffer element of the SenkouSpanA line by the specified index.

```
double SenkouSpanA(  
    int index    // index  
)
```

Parameters

index

[in] SenkouSpanA line buffer element index.

Return Value

The buffer element of the SenkouSpanA line of the specified index, or [EMPTY_VALUE](#) if there is no correct data.

SenkouSpanB

Returns the buffer element of the SenkouSpanB line by the specified index.

```
double SenkouSpanB(  
    int index    // index  
)
```

Parameters

index

[in] SenkouSpanB line buffer element index.

Return Value

The buffer element of the SenkouSpanB line of the specified index, or [EMPTY_VALUE](#) if there is no correct data.

ChinkouSpan

Returns the buffer element of the ChinkouSpan line by the specified index.

```
double ChinkouSpan(  
    int index    // index  
)
```

Parameters

index

[in] ChinkouSpan line buffer element index.

Return Value

The buffer element of the ChinkouSpan line of the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type ([IND_ICHIMOKU](#) for Cilchimoku).

CiMA

CiMA is a class intended for using the Moving Average technical indicator.

Description

CiMA class provides the creation, setup, and access to the data of the Moving Average indicator.

Declaration

```
class CiMA: public CIndicator
```

Title

```
#include <Indicators\Trend.mqh>
```

Inheritance hierarchy

MaPeriod

Returns the averaging period.

```
int MaPeriod() const
```

Return Value

Returns the averaging period, defined at the indicator creation.

MaShift

Returns the horizontal shift of the indicator.

```
int MaShift() const
```

Return Value

Returns the horizontal shift value, defined at the indicator creation.

MaMethod

Returns the averaging method.

```
ENUM_MA_METHOD MaMethod() const
```

Return Value

Returns the averaging method (value of [ENUM_MA_METHOD](#) enumeration), defined at the indicator creation.

Applied

Returns the price type or handle to apply.

```
int Applied() const
```

Return Value

Price type or handle to apply, defined at the indicator creation.

Create

Creates the indicator with specified parameters. Use [Refresh\(\)](#) and [GetData\(\)](#) to update and get the indicator values.

```
bool Create(  
    string          symbol,          // symbol

    int             ma_period,        // averaging period  
    int             ma_shift,         // shift  
    ENUM_MA_METHOD  ma_method,        // averaging method  
    int             applied           // price type, handle  
)
```

Parameters

string

[in] Symbol.

period

[in] Timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

ma_period

[in] Averaging period.

ma_shift

[in] Horizontal shift.

ma_method

[in] Averaging method ([ENUM_MA_METHOD](#) enumeration value).

applied

[in] Price type or handle to apply.

Return Value

true - successful, false - cannot create the indicator.

Main

Returns the buffer element by the specified index.

```
double Main(  
    int index    // index  
)
```

Parameters

index

[in] Buffer element index.

Return Value

Buffer element by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type ([IND_MA](#) for CiMA).

CiSAR

CiSAR is a class intended for using the Parabolic Stop And Reverse System technical indicator.

Description

CiSAR class provides the creation, setup, and access to the data of the Parabolic Stop And Reverse System indicator.

SarStep

Returns the step of price increment.

```
double SarStep() const
```

Return Value

The step of price increment, defined at the indicator creation.

Maximum

Returns the maximum value of the step.

```
double Maximum() const
```

Return Value

The maximum value of the step, defined at the indicator creation.

Create

Creates the indicator with specified parameters. Use [Refresh\(\)](#) and [GetData\(\)](#) to update and get the indicator values.

```
bool Create(  
    string          symbol,      // symbol

    double          step,        // step  
    double          maximum      // coefficient  
)
```

Parameters

symbol

[in] Symbol.

period

[in] Timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

step

[in] Step for the velocity increasing.

maximum

[in] Price following coefficient.

Return Value

true - successful, false - cannot change the indicator.

Main

Returns the buffer element by the specified index.

```
double Main(  
    int index    // index  
)
```

Parameters

index

[in] Buffer element index.

Return Value

Buffer element by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type ([IND_SAR](#) for CiSAR).

CiStdDev

CiStdDev is a class intended for using the Standard Deviation technical indicator.

Description

CiStdDev class provides the creation, setup, and access to the data of the Standard Deviation indicator.

MaPeriod

Returns the averaging period.

```
int MaPeriod() const
```

Return Value

Returns the averaging period, defined at the indicator creation.

MaShift

Returns the horizontal shift of the indicator.

```
int MaShift() const
```

Return Value

Returns the horizontal shift value, defined at the indicator creation.

MaMethod

Returns the averaging method.

```
ENUM_MA_METHOD MaMethod() const
```

Return Value

Returns the averaging method (value of [ENUM_MA_METHOD](#) enumeration), defined at the indicator creation.

Applied

Returns the price type or handle to apply.

```
int Applied() const
```

Return Value

Price type or handle to apply, defined at the indicator creation.

Create

Creates the indicator with specified parameters. Use [Refresh\(\)](#) and [GetData\(\)](#) to update and get the indicator values.

```
bool Create(  
    string          symbol,          // symbol  
    ENUM_TIMEFRAMES period,          // period  
    int             ma_period,       // averaging period  
    int             ma_shift,        // shift  
    ENUM_MA_METHOD  ma_method,       // averaging method  
    int             applied           // price type, handle  
)
```

Parameters

symbol

[in] Symbol.

period

[in] Timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

ma_period

[in] Averaging period.

ma_shift

[in] Horizontal shift.

ma_method

[in] Averaging method ([ENUM_MA_METHOD](#) enumeration value).

applied

[in] Price type or handle to apply.

Return Value

true - successful, false - cannot create the indicator.

Main

Returns the buffer element by the specified index.

```
double Main(  
    int index    // index  
)
```

Parameters

index

[in] Buffer element index.

Return Value

Buffer element by the specified index if successful, or [EMPTY_VALUE](#) if there is no correct data.

Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type ([IND_STDDEV](#) for CiStdDev).

CiDEMA

CiDEMA is a class intended for using the Double Exponential Moving Average technical indicator.

Description

CiDEMA class provides the creation, setup, and access to the data of the Double Exponential Moving Average indicator.

Declaration

```
class CiDEMA: public CIndicator
```

Title

```
#include <Indicators\Trend.mqh>
```

Inheritance hierarchy

MaPeriod

Returns the averaging period.

```
int MaPeriod() const
```

Return Value

Returns the averaging period, defined at the indicator creation.

IndShift

Returns the horizontal shift of the indicator.

```
int IndShift () const
```

Return Value

Returns the horizontal shift value, defined at the indicator creation.

Applied

Returns the price type or handle to apply.

```
int Applied() const
```

Return Value

Price type or handle to apply, defined at the indicator creation.

Create

Creates the indicator with specified parameters. Use [Refresh\(\)](#) and [GetData\(\)](#) to update and get the indicator values.

```
bool Create(

    int             applied          // price type, handle  
)
```

Parameters

string

[in] Symbol.

period

[in] Timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

ma_period

[in] Averaging period.

ind_shift

[in] Horizontal shift.

applied

[in] Price type or handle to apply.

Return Value

true - successful, false - cannot create the indicator.

Main

Returns the buffer element by the specified index.

```
double Main(  
    int index    // index  
)
```

Parameters

index

[in] Buffer element index.

Return Value

Buffer element of the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type ([IND_DEMA](#) for CiDEMA).

CiTEMA

CiTEMA is a class intended for using the Triple Exponential Moving Average technical indicator.

Description

CiTEMA class provides the creation, setup, and access to the data of the Triple Exponential Moving Average indicator.

)
```

Parameters

symbol

[in] Symbol.

period

[in] Timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

ma_period

[in] Averaging period.

ma_shift

[in] Horizontal shift.

applied

[in] Price type or handle to apply.

Return Value

true - successful, false - cannot create the indicator.

Main

Returns the buffer element by the specified index.

```
double Main(  
    int index    // index  
)
```

Parameters

index

[in] Buffer element index.

Return Value

Buffer element of the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type ([IND_TEMA](#) for CiTEMA).

CiFrAMA

CiFrAMA is a class intended for using the Fractal Adaptive Moving Average technical indicator.

Description

CiFrAMA class provides the creation, setup, and access to the data of the Fractal Adaptive Moving Average indicator.

MaPeriod

Returns the averaging period.

```
int MaPeriod() const
```

Return Value

Returns the averaging period, defined at the indicator creation.

FastEmaPeriod

Returns the averaging period for the fast EMA.

```
int FastEmaPeriod() const
```

Return Value

Returns the averaging period for the fast EMA, defined at the indicator creation.

SlowEmaPeriod

Returns the averaging period for the slow EMA.

```
int SlowEmaPeriod() const
```

Return Value

Returns the averaging period for the slow EMA, defined at the indicator creation.

IndShift

Returns the horizontal shift of the indicator.

```
int IndShift () const
```

Return Value

Returns the horizontal shift value, defined at the indicator creation.

Applied

Returns the price type or handle to apply.

```
int Applied() const
```

Return Value

Price type or handle to apply, defined at the indicator creation.

Create

Creates the indicator with specified parameters. Use [Refresh\(\)](#) and [GetData\(\)](#) to update and get the indicator values.

```
bool Create(  
    string          string,          // symbol

    int             slow_ema_period,  // slow EMA period  
    int             ind_shift,        // shift  
    int             applied           // price type, handle  
)
```

Parameters

string

[in] Symbol.

period

[in] Timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

ma_period

[in] Averaging period.

fast_ema_period

[in] Fast EMA averaging period.

slow_ema_period

[in] Slow EMA averaging period.

ind_shift

[in] Horizontal shift.

applied

[in] Price type or handle to apply.

Return Value

true - successful, false - cannot create the indicator.

Main

Returns the buffer element by the specified index.

```
double Main(  
    int index    // index  
)
```

Parameters

index

[in] Buffer element index.

Return Value

Buffer element of the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type ([IND_AMA](#) for CiAMA).

CiVIDyA

CiVIDyA is a class intended for using the Variable Index Dynamic Average technical indicator.

Description

CiVIDyA class provides the creation, setup, and access to the data of the Variable Index Dynamic Average indicator.

CmoPeriod

Closes the chart bound to the class instance.

```
int CmoPeriod() const
```

EmaPeriod

Returns the chart symbol.

```
int EmaPeriod() const
```

Return Value

Returns a chart symbol bound to a class instance. "" - no bound chart.

IndShift

Returns the horizontal shift of the indicator.

```
int IndShift () const
```

Return Value

Returns the horizontal shift value, defined at the indicator creation.

Applied

Returns the price type or handle to apply.

```
int Applied() const
```

Return Value

Price type or handle to apply, defined at the indicator creation.

Create

Creates the indicator with specified parameters. Use [Refresh\(\)](#) and [GetData\(\)](#) to update and get the indicator values.

```

    int             ind_shift,       // shift  
    int             applied           // price type, handle  
)
```

Parameters

symbol

[in] Symbol.

period

[in] Timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

cmo_period

[in] Momentum period.

ema_period

[in] Averaging period.

ind_shift

[in] Horizontal shift.

applied

[in] Price type or handle to apply.

Return Value

true - successful, false - cannot create the indicator.

Main

Returns the buffer element by the specified index.

```
double Main(  
    int index    // index  
)
```

Parameters

index

[in] Buffer element index.

Return Value

Buffer element by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type ([IND_VIDYA](#) for CiVIDyA).

Oscillator Classes

This group of chapters contains the technical details of Oscillators classes, as well as descriptions of the appropriate components of the MQL5 Standard Library.

Class/group	Description
<u>CiATR</u>	Average True Range
<u>CiBearsPower</u>	Bears Power
<u>CiBullsPower</u>	Bulls Power
<u>CiCCI</u>	Commodity Channel Index
<u>CiChaikin</u>	Chaikin Oscillator
<u>CiDeMarker</u>	DeMarker
<u>CiForce</u>	Force Index
<u>CiMACD</u>	Moving Averages Convergence-Divergence
<u>CiMomentum</u>	Momentum
<u>CiOsMA</u>	Moving Average of Oscillator (MACD histogram)
<u>CiRSI</u>	Relative Strength Index
<u>CiRVI</u>	Relative Vigor Index
<u>CiStochastic</u>	Stochastic Oscillator
<u>CiWPR</u>	Williams' Percent Range
<u>CiTriX</u>	Triple Exponential Moving Averages Oscillator

CiATR

CiATR is a class intended for using the Average True Range technical indicator.

Description

CiATR class provides the creation, setup, and access to the data of the Average True Range indicator.

Declaration

```
class CiATR: public CIndicator
```

Title

```
#include <Indicators\Oscilators.mqh>
```

Inheritance hierarchy

    int             ma_period        // averaging period  
)
```

Parameters

symbol

[in] Symbol.

period

[in] Timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

ma_period

[in] Averaging period.

Return Value

true - successful, false - cannot create the indicator.

Main

Returns the buffer element by the specified index.

```
double Main(  
    int index    // index  
)
```

Parameters

index

[in] Buffer element index.

Return Value

Buffer element by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type ([IND_ATR](#) for CiATR).

CiBearsPower

CiBearsPower is a class intended for using the Bears Power technical indicator.

Description

CiBearsPower class provides the creation, setup, and access to the data of the Bears Power indicator.

Declaration

MaPeriod

Returns the averaging period.

```
int MaPeriod() const
```

Return Value

Returns the averaging period, defined at the indicator creation.

Create

Creates the indicator with specified parameters. Use [Refresh\(\)](#) and [GetData\(\)](#) to update and get the indicator values.

```
bool Create(  
    string          symbol,          // symbol  
    ENUM_TIMEFRAMES period,          // period  
    int             ma_period        // averaging period  
)
```

Parameters

symbol

[in] Symbol.

period

[in] Timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

ma_period

[in] Averaging period.

Return Value

true - successful, false - cannot create the indicator.

Main

Returns the buffer element by the specified index.

```
double Main(  
    int index    // index  
)
```

Parameters

index

[in] Buffer element index.

Return Value

Buffer element by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type ([IND_BEARS](#) for CiBearsPower).

CiBullsPower

CiBullsPower is a class intended for using the Bulls Power technical indicator.

Description

CiBullsPower class provides the creation, setup, and access to the data of the Bulls Power indicator.

)
```

Parameters

symbol

[in] Symbol.

period

[in] Timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

ma_period

[in] Averaging period.

applied

[in] Price type or handle to apply.

Return Value

true - successful, false - cannot create the indicator.

Main

Returns the buffer element by the specified index.

```
double Main(  
    int index    // index  
)
```

Parameters

index

[in] Buffer element index.

Return Value

Buffer element by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type ([IND_CCI](#) for CiCCI).

CiChaikin

CiChaikin is a class intended for using the Chaikin Oscillator technical indicator.

Description

CiChaikin class provides the creation, setup, and access to the data of the Chaikin Oscillator indicator.

FastMaPeriod

Returns the averaging period for the fast EMA.

```
int FastMaPeriod() const
```

Return Value

Returns the averaging period for the fast EMA, defined at the indicator creation.

SlowMaPeriod

Returns the averaging period for the slow EMA.

```
int SlowMaPeriod() const
```

Return Value

Returns the averaging period for the slow EMA, defined at the indicator creation.

MaMethod

Returns the averaging method.

```
ENUM_MA_METHOD MaMethod() const
```

Return Value

Returns the averaging method, defined at the indicator creation ([ENUM_MA_METHOD](#) enumeration value).

Applied

Returns the object (volume type) to apply.

```
ENUM_APPLIED_VOLUME Applied() const
```

Return Value

Object (volume type) to apply, defined at the indicator creation ([ENUM_APPLIED_VOLUME](#) enumeration value).

Create

Creates the indicator with specified parameters. Use [Refresh\(\)](#) and [GetData\(\)](#) to update and get the indicator values.

```
bool Create(  
    string          symbol,          // symbol  
    ENUM_TIMEFRAMES period,          // period  
    int             fast_ma_period,  // fast EMA period  
    int             slow_ma_period,  // slow EMA period  
    ENUM_MA_METHOD  ma_method,       // averaging method  
    ENUM_APPLIED_VOLUME applied      // volume type  
)
```

Parameters

symbol

[in] Symbol.

period

[in] Timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

fast_ma_period

[in] Period for fast EMA.

slow_ma_period

[in] Period for slow EMA.

ma_method

[in] Averaging method ([ENUM_MA_METHOD](#) enumeration value).

applied

[in] Object (volume type) to apply ([ENUM_APPLIED_VOLUME](#) enumeration value).

Return Value

true - successful, false - cannot create the indicator.

Main

Returns the buffer element by the specified index.

```
double Main(  
    int index    // index  
)
```

Parameters

index

[in] Buffer element index.

Return Value

Buffer element by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type ([IND_CHAIKIN](#) for CiChaikin).

CiDeMarker

CiDeMarker is a class intended for using the DeMarker technical indicator.

Description

CiDeMarker class provides the creation, setup, and access to the data of the DeMarker indicator.

FastEmaPeriod

Returns the averaging period for the fast EMA.

```
int FastEmaPeriod() const
```

Return Value

Returns the averaging period for the fast EMA, defined at the indicator creation.

SlowEmaPeriod

Returns the averaging period for the slow EMA.

```
int SlowEmaPeriod() const
```

Return Value

Returns the averaging period for the slow EMA, defined at the indicator creation.

SignalPeriod

Returns the averaging period for the signal line.

```
int SignalPeriod() const
```

Return Value

Returns the averaging period for the signal line, defined at the indicator creation.

Applied

Returns the price type or handle to apply.

```
int Applied() const
```

Return Value

Price type or handle to apply, defined at the indicator creation.

Create

Creates the indicator with specified parameters. Use [Refresh\(\)](#) and [GetData\(\)](#) to update and get the indicator values.

```
bool Create(

    int             signal_period,    // signal period  
    int             applied           // price type, handle  
)
```

Parameters

symbol

[in] Symbol.

period

[in] Timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

fast_ema_period

[in] Fast EMA averaging period.

slow_ema_period

[in] Slow EMA averaging period.

signal_period

[in] Signal line averaging period.

applied

[in] Price type or handle to apply.

Return Value

true - successful, false - cannot create the indicator.

Main

Returns the main line buffer element by the specified index.

```
double Main(  
    int index    // index  
)
```

Parameters

index

[in] Buffer element index.

Return Value

Main line buffer element by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Signal

Returns the buffer element of the signal line by the specified index.

```
double Signal(  
    int index    // index  
)
```

Parameters

index

[in] Buffer element index.

Return Value

The buffer element of the signal line by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type ([IND_MACD](#) for CiMACD).

CiMomentum

CiMomentum is a class intended for using the Momentum technical indicator.

Description

CiMomentum class provides the creation, setup, and access to the data of the Momentum indicator.

bool Create(  
    string          symbol,          // symbol  
    ENUM_TIMEFRAMES period,          // period  
    int             ma_period,        // averaging period  
    int             applied           // price type, handle  
)
```

Parameters

symbol

[in] Symbol.

period

[in] Timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

ma_period

[in] Averaging period.

applied

[in] Price type or handle to apply.

Return Value

true - successful, false - cannot create the indicator.

Main

Returns the buffer element by the specified index.

```
double Main(  
    int index    // index  
)
```

Parameters

index

[in] Buffer element index.

Return Value

Buffer element by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type ([IND_MOMENTUM](#) for CiMomentum).

CiOsMA

CiOsMA is a class intended for using the Moving Average of Oscillator (MACD histogram) technical indicator.

Description

CiOsMA class provides the creation, setup, and access to the data of the Moving Average of Oscillator (MACD histogram) indicator.

Declaration

```
class CiOsMA: public CIndicator
```

Title

```
#include <Indicators\Oscillators.mqh>
```

Inheritance hierarchy

FastEmaPeriod

Returns the averaging period for the fast EMA.

```
int FastEmaPeriod() const
```

Return Value

Returns the averaging period for the fast EMA, defined at the indicator creation.

SlowEmaPeriod

Returns the averaging period for the slow EMA.

```
int SlowEmaPeriod() const
```

Return Value

Returns the averaging period for the slow EMA, defined at the indicator creation.

SignalPeriod

Returns the averaging period for the signal line.

```
int SignalPeriod() const
```

Return Value

Returns the averaging period for the signal line, defined at the indicator creation.

Applied

Returns the price type or handle to apply.

```
int Applied() const
```

Return Value

Price type or handle to apply, defined at the indicator creation.

Create

Creates the indicator with specified parameters. Use [Refresh\(\)](#) and [GetData\(\)](#) to update and get the indicator values.

```
bool Create(  
    string          symbol,           // symbol  
    ENUM_TIMEFRAMES period,          // period  
    int             fast_ema_period,  // fast EMA period  
    int             slow_ema_period,  // slow EMA period  
    int             signal_period,    // signal line period  
    int             applied           // price type, handle  
)
```

Parameters

symbol

[in] Symbol.

period

[in] Timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

fast_ema_period

[in] Fast EMA averaging period.

slow_ema_period

[in] Slow EMA averaging period.

signal_period

[in] Signal line averaging period.

applied

[in] Price type or handle to apply.

Return Value

true - successful, false - cannot create the indicator.

Main

Returns the buffer element by the specified index.

```
double Main(  
    int index    // index  
)
```

Parameters

index

[in] Buffer element index.

Return Value

Buffer element by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type ([IND_OSMA](#) for CiOsMA).

CiRSI

CiRSI is a class intended for using the Relative Strength Index technical indicator.

Description

CiRSI class provides the creation, setup, and access to the data of the Relative Strength Index indicator.

)
```

Parameters

symbol

[in] Symbol.

period

[in] Timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

ma_period

[in] Averaging period.

applied

[in] Price type or handle to apply.

Return Value

true - successful, false - cannot create the indicator.

Main

Returns the buffer element by the specified index.

```
double Main(  
    int index    // index  
)
```

Parameters

index

[in] Buffer element index.

Return Value

Buffer element by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type ([IND_RSI](#) for CiRSI).

CiRVI

CiRVI is a class intended for using the Relative Vigor Index technical indicator.

Description

CiRVI class provides the creation, setup, and access to the data of the Relative Vigor Index indicator.

Parameters

symbol

[in] Symbol.

period

[in] Timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

ma_period

[in] Averaging period.

Return Value

true - successful, false - cannot create the indicator.

Main

Returns the main line buffer element by the specified index.

```
double Main(  
    int index    // index  
)
```

Parameters

index

[in] Buffer element index.

Return Value

Main line buffer element by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Signal

Returns the buffer element of the signal line by the specified index.

```
double Signal(  
    int index    // index  
)
```

Parameters

index

[in] Buffer element index.

Return Value

The buffer element of the signal line by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type ([IND_RVI](#) for CiRVI).

CiStochastic

CiStochastic is a class intended for using the Stochastic Oscillator technical indicator.

Description

CiStochastic class provides the creation, setup, and access to the data of the Stochastic Oscillator indicator.

Kperiod

Returns the averaging period for the %K line.

```
int Kperiod() const
```

Return Value

Returns the averaging period for the %K line, defined at the indicator creation.

Dperiod

Returns the averaging period for the %D line.

```
int Dperiod() const
```

Return Value

Returns the averaging period for the %D line, defined at the indicator creation.

Slowing

Returns the period of slowing.

```
int Slowing() const
```

Return Value

Returns the period of slowing, defined at the indicator creation.

MaMethod

Returns the averaging method.

```
ENUM_MA_METHOD MaMethod() const
```

Return Value

Returns the averaging method, defined at the indicator creation ([ENUM_MA_METHOD](#) enumeration value).

PriceField

Returns the object (Low/High or Close/Close) to apply.

```
ENUM_STO_PRICE PriceField() const
```

Return Value

The object (Low/High or Close/Close) to apply, defined at the indicator creation ([ENUM_STO_PRICE](#) enumeration value).

Create

Creates the indicator with specified parameters. Use [Refresh\(\)](#) and [GetData\(\)](#) to update and get the indicator values.

```
bool Create(  
    string          symbol,          // symbol  
    ENUM_TIMEFRAMES period,          // period  
    int             Kperiod,         // %K period  
    int             Dperiod,         // %D period  
    int             slowing,         // slowing period  
    ENUM_MA_METHOD  ma_method,       // averaging method  
    ENUM_STO_PRICE  price_field      // application  
)
```

Parameters

symbol

[in] Symbol.

period

[in] Timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

Kperiod

[in] Averaging period of %K indicator.

Dperiod

[in] Averaging period of %D indicator.

slowing

[in] Slowing period.

ma_method

[in] Averaging method ([ENUM_MA_METHOD](#) enumeration value).

price_field

[in] Object (Low/High or Close/Close) to apply ([ENUM_STO_PRICE](#) enumeration value).

Return Value

true - successful, false - cannot create the indicator.

Main

Returns the main line buffer element by the specified index.

```
double Main(  
    int index    // index  
)
```

Parameters

index

[in] Buffer element index.

Return Value

Main line buffer element by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Signal

Returns the buffer element of the signal line by the specified index.

```
double Signal(  
    int index    // index  
)
```

Parameters

index

[in] Buffer element index.

Return Value

The buffer element of the signal line by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type ([IND_STOCHASTIC](#) for CiStochastic).

CiTriX

CiTriX is a class intended for using the Triple Exponential Moving Averages Oscillator technical indicator.

Description

CiTriX class provides the creation, setup, and access to the data of the Triple Exponential Moving Averages Oscillator indicator.

Parameters

symbol

[in] Symbol.

period

[in] Timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

calc_period

[in] Period for calculation.

Return Value

true - successful, false - cannot create the indicator.

Main

Returns the buffer element by the specified index.

```
double Main(  
    int index    // index  
)
```

Parameters

index

[in] Buffer element index.

Return Value

Buffer element by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type ([IND_WPR](#) for CiWPR).

Volume Indicators

This group of chapters contains technical details of Volume indicator classes and descriptions of all the appropriate key components of the MQL5 Standard Library.

```

Parameters

symbol

[in] Symbol.

period

[in] Timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

applied

[in] Volume type to apply ([ENUM_APPLIED_VOLUME](#) enumeration value).

Return Value

true - successful, false - cannot create the indicator.

Main

Returns the buffer element by the specified index.

```
double Main(  
    int index    // index  
)
```

Parameters

index

[in] Buffer element index.

Return Value

Buffer element by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type ([IND_AD](#) for CiAD).

CiMFI

CiMFI is a class intended for using the Money Flow Index technical indicator.

Description

CiMFI class provides the creation, setup, and access to the data of the Money Flow Index indicator.

Declaration

```
class CiMFI: public CIndicator
```

Title

```
#include <Indicators\Volumes.mqh>
```

MaPeriod

Returns the averaging period.

```
int MaPeriod() const
```

Return Value

Returns the averaging period, defined at the indicator creation.

Applied

Returns the volume type to apply.

```
ENUM_APPLIED_VOLUME Applied() const
```

Return Value

Volume type to apply, defined at the indicator creation ([ENUM_APPLIED_VOLUME](#) enumeration value).

Create

Creates the indicator with specified parameters. Use [Refresh\(\)](#) and [GetData\(\)](#) to update and get the indicator values.

```
bool Create(  
    string          symbol,          // symbol  
    ENUM_TIMEFRAMES period,          // period  
    int             ma_period,        // averaging period  
    ENUM_APPLIED_VOLUME applied       // volume type  
)
```

Parameters

symbol

[in] Symbol.

period

[in] Timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

ma_period

[in] Averaging period.

applied

[in] Volume type to apply ([ENUM_APPLIED_VOLUME](#) enumeration value).

Return Value

true - successful, false - cannot create the indicator.

Main

Returns the buffer element by the specified index.

```
double Main(  
    int index    // index  
)
```

Parameters

index

[in] Buffer element index.

Return Value

Buffer element by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type ([IND_MFI](#) for CiMFI).

CiOBV

CiOBV is a class intended for using the On Balance Volume technical indicator.

Description

CiOBV class provides the creation, setup, and access to the data of the On Balance Volume indicator.

Declaration

```
class CiOBV: public CIndicator
```

Title

```
#include <Indicators\Volumes.mqh>
```

Inheritance hierarchy

Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type ([IND_VOLUMES](#) for CiVolumes).

Bill Williams Indicators

This group of chapters contains technical details of Bill Williams indicator classes and descriptions of all the appropriate components of the MQL5 Standard Library.

Class/group	Description
<u>CiAC</u>	Accelerator Oscillator
<u>CiAlligator</u>	Alligator
<u>CiAO</u>	Awesome Oscillator
<u>CiFractals</u>	Fractals
<u>CiGator</u>	Gator Oscillator
<u>CiBWMFI</u>	Market Facilitation Index

CiAC

CiAC is a class intended for using the Accelerator Oscillator technical indicator.

Description

CiAC class provides the creation, setup, and access to the data of the Accelerator Oscillator indicator.

Declaration

```
class CiAC: public CIndicator
```

Title

```
#include <Indicators\BillWilliams.mqh>
```

JawPeriod

Returns the averaging period for the Jaw line.

```
int  JawPeriod() const
```

Return Value

Returns the averaging period for the Jaw line, defined at the indicator creation.

JawShift

Returns the horizontal shift of the Jaws line.

```
int  JawShift () const
```

Return Value

Horizontal shift of the Jaws line, defined at the indicator creation.

TeethPeriod

Returns the averaging period for the Teeth line.

```
int TeethPeriod() const
```

Return Value

Returns the averaging period for the Teeth line, defined at the indicator creation.

TeethShift

Returns the horizontal shift of the Teeth line.

```
int TeethShift() const
```

Return Value

Horizontal shift of the Teeth line, defined at the indicator creation.

LipsPeriod

Returns the averaging period for the Lips line.

```
int LipsPeriod() const
```

Return Value

Returns the averaging period for the Lips line, defined at the indicator creation.

LipsShift

Returns the horizontal shift of the Lips line.

```
int LipsShift() const
```

Return Value

Horizontal shift of the Lips line, defined at the indicator creation.

MaMethod

Returns the averaging method.

```
ENUM_MA_METHOD MaMethod() const
```

Return Value

Returns the averaging method, defined at the indicator creation.

Applied

Returns the price type or handle to apply.

```
int Applied() const
```

Return Value

Price type or handle to apply, defined at the indicator creation.

Create

Creates the indicator with specified parameters. Use [Refresh\(\)](#) and [GetData\(\)](#) to update and get the indicator values.

```
bool Create(
    string          symbol,           // symbol
    ENUM_TIMEFRAMES period,          // period
    int             jaw_period,       // jaws period
    int             jaw_shift,        // jaws shift
    int             teeth_period,     // teeth period
    int             teeth_shift,      // teeth shift
    int             lips_period,      // lips period
    int             lips_shift,       // lips shift
    ENUM_MA_METHOD  ma_method,       // averaging method
    int             applied           // price type, handle
)
```

Parameters

symbol

[in] Symbol.

period

[in] Timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

jaw_period

[in] Jaws averaging period.

jaw_shift

[in] Jaws horizontal shift.

teeth_period

[in] Teeth averaging period.

teeth_shift

[in] Teeth horizontal shift.

lips_period

[in] Lips averaging period.

lips_shift

[in] Lips horizontal shift.

ma_method

[in] Moving average method ([ENUM_MA_METHOD](#) enumeration value).

applied

[in] Price type, handle to apply.

Return Value

true - successful, false - cannot create the indicator.

Jaw

Returns the buffer element of the Jaws line by the specified index.

```
double  Jaw(  
    int  index    // index  
)
```

Parameters

index

[in] Jaws line buffer element index.

Return Value

The buffer element of the Jaws line by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Teeth

Returns the buffer element of the Teeth line by the specified index.

```
double Teeth(  
    int index    // index  
)
```

Parameters

index

[in] Teeth line buffer element index.

Return Value

The buffer element of the Teeth line by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Lips

Returns the buffer element of the Lips line by the specified index.

```
double Lips(  
    int index    // index  
)
```

Parameters

index

[in] Lips line buffer element index.

Return Value

The buffer element of the Lips line by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type ([IND_ALLIGATOR](#) for CiAlligator).

CiAO

CiAO is a class intended for using the Awesome Oscillator technical indicator.

Description

CiAO class provides the creation, setup, and access to the data of the Awesome Oscillator indicator.

Declaration

```
class CiAO: public CIndicator
```

Title

```
#include <Indicators\BillWilliams.mqh>
```

    ENUM_TIMEFRAMES period      // period  
)
```

Parameters

symbol

[in] Symbol.

period

[in] Timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

Return Value

true - successful, false - cannot create the indicator.

Main

Returns the buffer element by the specified index.

```
double Main(  
    int index    // index  
)
```

Parameters

index

[in] Buffer element index.

Return Value

Buffer element of the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type ([IND_AO](#) for CiAO).

CiFractals

CiFractals is a class intended for using the Fractals technical indicator.

Description

CiFractals class provides the creation, setup, and access to the data of the Fractals indicator.

Declaration

```

Parameters

symbol

[in] Symbol.

period

[in] Timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

Return Value

true - successful, false - cannot create the indicator.

Upper

Returns the element of the upper buffer by the specified index.

```
double Upper (  
    int index    // index  
)
```

Parameters

index

[in] Upper buffer element index.

Return Value

The element of the upper buffer by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Lower

Returns the element of the lower buffer by the specified index.

```
double Lower (  
    int index    // index  
)
```

Parameters

index

[in] Lower buffer element index.

Return Value

The element of the lower buffer by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type ([IND_FRACTALS](#) for CiFractals).

CiGator

CiGator is a class intended for using the Gator Oscillator technical indicator.

Description

CiGator class provides the creation, setup, and access to the data of the Gator Oscillator indicator.

JawPeriod

Returns the averaging period for the Jaws line.

```
int JawPeriod() const
```

Return Value

Returns the averaging period for the Jaws line, defined at the indicator creation.

JawShift

Returns the horizontal shift of the Jaws line.

```
int  JawShift () const
```

Return Value

Horizontal shift of the Jaws line, defined at the indicator creation.

TeethPeriod

Returns the averaging period for the Teeth line.

```
int TeethPeriod() const
```

Return Value

Returns the averaging period for the Teeth line, defined at the indicator creation.

TeethShift

Returns the horizontal shift of the Teeth line.

```
int TeethShift() const
```

Return Value

Horizontal shift of the Teeth line, defined at the indicator creation.

LipsPeriod

Returns the averaging period for the Lips line.

```
int LipsPeriod() const
```

Return Value

Returns the averaging period for the Lips line, defined at the indicator creation.

LipsShift

Returns the horizontal shift of the Lips line.

```
int LipsShift() const
```

Return Value

Horizontal shift of the Lips line, defined at the indicator creation.

MaMethod

Returns the averaging method.

```
ENUM_MA_METHOD MaMethod() const
```

Return Value

Returns the averaging method, defined at the indicator creation.

Applied

Returns the price type or handle to apply.

```
int Applied() const
```

Return Value

Price type or handle to apply, defined at the indicator creation.

Create

Creates the indicator with specified parameters. Use [Refresh\(\)](#) and [GetData\(\)](#) to update and get the indicator values.

```
bool Create(
    string          symbol,           // symbol
    ENUM_TIMEFRAMES period,          // period
    int             jaw_period,       // jaws period
    int             jaw_shift,        // jaws shift
    int             teeth_period,     // teeth period
    int             teeth_shift,      // teeth shift
    int             lips_period,      // lips period
    int             lips_shift,       // lips shift
    ENUM_MA_METHOD  ma_method,       // averaging method
    int             applied           // price type, handle
)
```

Parameters

symbol

[in] Symbol.

period

[in] Timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

jaw_period

[in] Jaws averaging period.

jaw_shift

[in] Jaws horizontal shift.

teeth_period

[in] Teeth averaging period.

teeth_shift

[in] Teeth horizontal shift.

lips_period

[in] Lips averaging period.

lips_shift

[in] Lips horizontal shift.

ma_method

[in] Averaging method ([ENUM_MA_METHOD](#) enumeration value).

applied

[in] Price type or handle to apply.

Return Value

true - successful, false - cannot create the indicator.

Upper

Returns the element of the upper buffer by the specified index.

```
double Upper (  
    int index    // index  
)
```

Parameters

index

[in] Upper buffer element index.

Return Value

The upper buffer element by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Lower

Returns the element of the lower buffer by the specified index.

```
double Upper (  
    int index    // index  
)
```

Parameters

index

[in] Lower buffer element index.

Return Value

The element of the lower buffer by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type ([IND_GATOR](#) for CiGator).

CiBWMFI

CiBWMFI is a class intended for using the Market Facilitation Index by Bill Williams technical indicator.

Description

CiBWMFI class provides the creation, setup, and access to the data of the Market Facilitation Index by Bill Williams indicator.

Declaration

```
class CiBWMFI: public CIndicator
```

Title

```
#include <Indicators\BillWilliams.mqh>
```

Inheritance hierarchy

Applied

Returns the volume type to apply.

```
ENUM_APPLIED_VOLUME Applied() const
```

Return Value

Volume type to apply, defined at the indicator creation ([ENUM_APPLIED_VOLUME](#) enumeration value).

Create

Creates the indicator with specified parameters. Use [Refresh\(\)](#) and [GetData\(\)](#) to update and get the indicator values.

```
bool Create(  
    string          symbol,      // symbol  
    ENUM_TIMEFRAMES period,      // period  
    ENUM_APPLIED_VOLUME applied  // volume type  
)
```

Parameters

symbol

[in] Symbol.

period

[in] Timeframe ([ENUM_TIMEFRAMES](#) enumeration value).

applied

[in] Volume type to apply ([ENUM_APPLIED_VOLUME](#) enumeration value).

Return Value

true - successful, false - cannot create the indicator.

Main

Returns the buffer element by the specified index.

```
double Main(  
    int index    // index  
)
```

Parameters

index

[in] Buffer element index.

Return Value

Buffer element by the specified index, or [EMPTY_VALUE](#) if there is no correct data.

Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type ([IND_BWMFI](#) for CiBWMFI).

CiCustom

CiCustom is a class intended for using the custom technical indicators.

Description

CiCustom class provides the creation, setup, and access to the data of a custom indicator.

Declaration

```
class CiCustom: public CIndicator
```

Title

```
#include <Indicators\Custom.mqh>
```

Class Methods by Groups

Attributes	
NumBuffers	Sets the number of buffers
NumParams	Gets the number of parameters used when creating an indicator
ParamType	Gets the type of the specified parameter
ParamLong	Gets the value of the specified parameter of integer type
ParamDouble	Gets the value of the specified parameter of double type
ParamString	Gets the value of the specified parameter of string type
Input/output	
virtual Type	Virtual identification method

NumBuffers

Sets the number of buffers.

```
bool NumBuffers (
```

Return Value

true - successful, false - cannot set the necessary number of buffers.

NumParams

Gets the number of parameters used when creating an indicator.

```
int NumParams() const
```

Return Value

Number of parameters, used in creation of the indicator.

ParamType

Gets a type of the parameter.

```
ENUM_DATATYPE ParamType(  
    int index    // index  
) const
```

Parameters

index

[in] Parameter index.

Return Value

Returns the data type of the specified parameter, used in indicator creation.

Note

If parameter index is invalid, it returns [WRONG_VALUE](#).

ParamLong

Gets the value of specified parameter of long type.

```
long ParamLong(  
    int index    // index  
    ) const
```

Parameters

index

[in] Parameter index.

Return Value

The value of specified parameter of long type, used in creation of the indicator.

Note

If the parameter index is invalid or the parameter is not of long type, it returns 0.

ParamDouble

Gets the value of specified parameter of double type.

```
double ParamDouble(  
    int index    // index  
) const
```

Parameters

index

[in] Parameter index.

Return Value

The value of specified parameter of double type, used in creation of the indicator.

Note

If the parameter index is invalid or the parameter type is not of double type, it returns [EMPTY_VALUE](#).

ParamString

Gets the value of specified parameter of string type.

```
string ParamString(  
    int index    // index  
    ) const
```

Parameters

index

[in] Parameter index.

Return Value

The value of specified string parameter, used in creation of the indicator.

Note

If the number is invalid or the parameter is not of string type, it returns an empty string.

Type

Virtual identification method.

```
virtual int Type() const
```

Return Value

Indicator type ([IND_CUSTOM](#) for CiCustom).

Trade Classes

This section contains technical details of working with trade classes and description of the relevant components of the MQL5 standard library.

Using trade classes will save time when creating custom programs (Expert Advisors).

MQL5 Standard Library (in terms of trade classes) is placed in the terminal working directory, in the Include\Trade folder.

Class/Group	Description
<u>CAccountInfo</u>	Class for working with trade account properties
<u>CSymbolInfo</u>	Class for working with trade instrument properties
<u>COrderInfo</u>	Class for working with pending order properties
<u>CHistoryOrderInfo</u>	Class for working with history order properties
<u>CPositionInfo</u>	Class for working with open position properties
<u>CDealInfo</u>	Class for working with history deal properties
<u>CTrade</u>	Class for trade operations execution
<u>CTerminalInfo</u>	Class for getting the properties of the terminal environment

CAccountInfo

CAccountInfo is a class for easy access to the currently opened trade account properties.

Description

CAccountInfo class provides easy access to the currently opened trade account properties.

Declaration

```
class CAccountInfo : public CObject
```

Title

```
#include <Trade\AccountInfo.mqh>
```

Inheritance hierarchy

CObject

CAccountInfo

Class methods by groups

Access to integer type properties	
<u>Login</u>	Gets the account number
<u>TradeMode</u>	Gets the trade mode
<u>TradeModeDescription</u>	Gets the trade mode as a string
<u>Leverage</u>	Gets the amount of given leverage
<u>StopoutMode</u>	Gets the mode of stop out setting
<u>StopoutModeDescription</u>	Gets the mode of stop out setting as a string
<u>TradeAllowed</u>	Gets the flag of trade allowance
<u>TradeExpert</u>	Gets the flag of automated trade allowance
<u>LimitOrders</u>	Gets the maximal number of allowed pending orders
<u>MarginMode</u>	Gets margin calculation mode
<u>MarginModeDescription</u>	Gets margin calculation mode as a string
Access to double type properties	
<u>Balance</u>	Gets the balance of account
<u>Credit</u>	Gets the amount of given credit
<u>Profit</u>	Gets the amount of current profit on account
<u>Equity</u>	Gets the amount of current equity on account

Margin	Gets the amount of reserved margin
FreeMargin	Gets the amount of free margin
MarginLevel	Gets the level of margin
MarginCall	Gets the level of margin for deposit
MarginStopOut	Gets the level of margin for Stop Out
Access to text properties	
Name	Gets the client name
Server	Gets the trade server name
Currency	Gets the deposit currency name
Company	Gets the company name that serves an account
Access to MQL5 API functions	
InfoInteger	Gets the value of specified integer type property
InfoDouble	Gets the value of specified double type property
InfoString	Gets the value of specified string type property
Additional methods	
OrderProfitCheck	Gets the evaluated profit based on the parameters passed
MarginCheck	Gets the amount of margin required to execute trade operation
FreeMarginCheck	Gets the amount of free margin left after execution of trade operation
MaxLotCheck	Gets the maximal possible volume of trade operation

Methods inherited from class CObject

Prev, Prev, Next, Next, [Save](#), [Load](#), [Type](#), [Compare](#)

Login

Gets the account number.

```
long Login() const
```

Return Value

Account number.

TradeMode

Gets the trade mode.

```
ENUM_ACCOUNT_TRADE_MODE TradeMode() const
```

Return Value

Trade mode from the [ENUM_ACCOUNT_TRADE_MODE](#) enumeration.

TradeModeDescription

Gets the trade mode as a string.

```
string TradeModeDescription() const
```

Return Value

Trade mode as a string.

Leverage

Gets the amount of given leverage.

```
long Leverage() const
```

Return Value

Amount of given leverage.

StopoutMode

Gets the mode of the Stop Out level specification.

```
ENUM_ACCOUNT_STOPOUT_MODE StopoutMode() const
```

Return Value

The stop out setting mode from the [ENUM_ACCOUNT_STOPOUT_MODE](#) enumeration.

StopoutModeDescription

Gets the mode of the Stop Out level specification as a string.

```
string StopoutModeDescription() const
```

Return Value

The stop out setting mode as a string.

MarginMode

Gets the margin calculation mode.

```
ENUM_ACCOUNT_MARGIN_MODE MarginMode() const
```

Return Value

The margin calculation mode from the [ENUM_ACCOUNT_MARGIN_MODE](#) enumeration.

MarginModeDescription

Gets the margin calculation mode as a string.

```
string MarginModeDescription() const
```

Return Value

Margin calculation mode as a string.

TradeAllowed

Gets the flag of trade allowance.

```
bool TradeAllowed() const
```

Return Value

Flag of trade allowance.

TradeExpert

Gets the flag of automated trade allowance.

```
bool TradeExpert() const
```

Return Value

Flag of automated trade allowance.

LimitOrders

Gets the maximal number of allowed pending orders

```
int LimitOrders() const
```

Return Value

The maximal number of allowed pending orders.

Note

0 - no limits.

Balance

Gets the balance of account.

```
double Balance() const
```

Return Value

The balance of account (in deposit currency).

Credit

Gets the amount of given credit.

```
double Credit() const
```

Return Value

Amount of given credit (in deposit currency).

Profit

Gets the amount of current profit on account.

```
double Profit() const
```

Return Value

Amount of current profit on account (in deposit currency).

Equity

Gets the amount of current equity on account.

```
double Equity() const
```

Return Value

Amount of current equity on account (in deposit currency).

Margin

Gets the amount of reserved margin.

```
double Margin() const
```

Return Value

Amount of reserved margin (in deposit currency).

FreeMargin

Gets the amount of free margin.

```
double FreeMargin() const
```

Return Value

Amount of free margin (in deposit currency).

MarginLevel

Gets the level of margin.

```
double MarginLevel() const
```

Return Value

Level of margin.

MarginCall

Gets the level of margin for a deposit.

```
double MarginCall() const
```

Return Value

Level of margin for a deposit.

MarginStopOut

Gets the level of margin for Stop Out.

```
double MarginStopOut () const
```

Return Value

Level of margin for Stop Out.

Name

Gets the client name.

```
string Name() const
```

Return Value

Client name.

Server

Gets the trade server name.

```
string Server() const
```

Return Value

Trade server name.

Currency

Gets the deposit currency name.

```
string Currency() const
```

Return Value

Deposit currency name.

Company

Gets the company name, that serves an account.

```
string Company() const
```

Return Value

Company name that serves an account.

InfoInteger

Gets the value of specified integer type property.

```
long InfoInteger(  
    ENUM_ACCOUNT_INFO_INTEGER prop_id    // property ID  
) const
```

Parameters

prop_id

[in] Identifier of the property. The value can be one of the values of [ENUM_ACCOUNT_INFO_INTEGER](#) enumeration.

Return Value

Value of [long](#) type.

InfoDouble

Gets the value of specified double type property.

```
double InfoDouble(  
    ENUM_ACCOUNT_INFO_DOUBLE prop_id // property ID  
) const
```

Parameters

prop_id

[in] Identifier of the property. The value can be one of the values of [ENUM_ACCOUNT_INFO_DOUBLE](#) enumeration.

Return Value

Value of [double](#) type.

InfoString

Gets the value of specified string type property.

```
string InfoString(  
    ENUM_ACCOUNT_INFO_STRING prop_id    // property ID  
) const
```

Parameters

prop_id

[in] Identifier of the property. The value can be one of the values of [ENUM_ACCOUNT_INFO_STRING](#) enumeration.

Return Value

Value of [string](#) type.

OrderProfitCheck

The function calculates the profit for the current account, based on the parameters passed. The function is used for pre-evaluation of the result of a trade operation. The value is returned in the account currency.

```
double OrderProfitCheck(  
    const string      symbol,           // symbol  
    ENUM_ORDER_TYPE   trade_operation,  // order type (ORDER_TYPE_BUY or ORDER_TYP  
    double            volume,           // volume  
    double            price_open,       // position open price  
    double            price_close       // position close price  
) const
```

Parameters

symbol

[in] Symbol for trade operation.

trade_operation

[in] Type of trade operation from [ENUM_ORDER_TYPE](#) enumeration.

volume

[in] Volume of trade operation.

price_open

[in] Open price.

price_close

[in] Close price.

Return Value

If successful, it returns amount of profit or [EMPTY_VALUE](#) in the case of error.

MarginCheck

Gets the amount of margin, required for trade operation.

```
double MarginCheck(  
    const string      symbol,           // symbol  
    ENUM_ORDER_TYPE   trade_operation, // order type (ORDER_TYPE_BUY or ORDER_TYPE_SELL)  
    double            volume,          // volume  
    double            price            // price  
) const
```

Parameters

symbol

[in] Symbol for trade operation.

trade_operation

[in] Type of trade operation from [ENUM_ORDER_TYPE](#) enumeration.

volume

[in] Volume of trade operation.

price

[in] Price of trade operation.

Return Value

Amount of margin required for trade operation.

FreeMarginCheck

Gets the amount of free margin left after trade operation.

```
double FreeMarginCheck(  
    const string      symbol,           // symbol  
    ENUM_ORDER_TYPE   trade_operation,  // order type (ORDER_TYPE_BUY or ORDER_TYPE_SELL)  
    double            volume,          // volume  
    double            price            // price  
) const
```

Parameters

symbol

[in] Symbol for trade operation.

trade_operation

[in] Type of trade operation from [ENUM_ORDER_TYPE](#) enumeration.

volume

[in] Volume of trade operation.

price

[in] Price of trade operation.

Return Value

Amount of free margin left after trade operation.

MaxLotCheck

Gets the maximum possible volume of trade operation.

```
double MaxLotCheck(  
    const string      symbol,           // symbol  
    ENUM_ORDER_TYPE   trade_operation,  // order type (ORDER_TYPE_BUY or ORDER_TYP  
    double            price,           // price  
    double            percent=100      // percent of available margin (default is  
) const
```

Parameters

symbol

[in] Symbol for trade operation.

trade_operation

[in] Type of trade operation from [ENUM_ORDER_TYPE](#) enumeration.

price

[in] Price of trade operation.

percent=100

[in] Percent of available margin (in %) to be used for trade operation.

Return Value

Maximum possible volume of trade operation.

CSymbolInfo

CSymbolInfo is a class for easy access to the symbol properties.

Description

CSymbolInfo class provides access to the symbol properties.

Declaration

```
class CSymbolInfo : public CObject
```

Title

```
#include <Trade\SymbolInfo.mqh>
```

Inheritance hierarchy

[CObject](#)

CSymbolInfo

Class methods by groups

Controlling	
Refresh	Refreshes the symbol data
RefreshRates	Refreshes the symbol quotes
Properties	
Name	Gets/sets symbol name
Select	Gets/sets the "Market Watch" symbol flag
IsSynchronized	Checks the symbol synchronization with server
Volumes	
Volume	Gets the volume of last deal
VolumeHigh	Gets the maximal volume for a day
VolumeLow	Gets the minimal volume for a day
Miscellaneous	
Time	Gets the time of last quote
Spread	Gets the amount of spread (in points)
SpreadFloat	Gets the flag of floating spread
TicksBookDepth	Gets the depth of ticks saving
Levels	

<u>StopsLevel</u>	Gets the minimal indent for orders (in points)
<u>FreezeLevel</u>	Gets the distance of freezing trade operations (in points)
Bid prices	
<u>Bid</u>	Gets the current Bid price
<u>BidHigh</u>	Gets the maximal Bid price for a day
<u>BidLow</u>	Gets the minimal Bid price for a day
Ask prices	
<u>Ask</u>	Gets the current Ask price
<u>AskHigh</u>	Gets the maximal Ask price for a day
<u>AskLow</u>	Gets the minimal Ask price for a day
Prices	
<u>Last</u>	Gets the current Last price
<u>LastHigh</u>	Gets the maximal Last price for a day
<u>LastLow</u>	Gets the minimal Last price for a day
Trade modes	
<u>TradeCalcMode</u>	Gets the mode of contract cost calculation
<u>TradeCalcModeDescription</u>	Gets the mode of contract cost calculation as a string
<u>TradeMode</u>	Gets the type of order execution
<u>TradeModeDescription</u>	Gets the type of order execution as a string
<u>TradeExecution</u>	Gets the trade execution mode
<u>TradeExecutionDescription</u>	Gets the execution mode as a string
Swaps	
<u>SwapMode</u>	Gets the swap calculation mode
<u>SwapModeDescription</u>	Gets the swap calculation mode as a string
<u>SwapRollover3days</u>	Gets the day of triple swap charge
<u>SwapRollover3daysDescription</u>	Gets the day of triple swap charge as a string
Margins and flags	
<u>MarginInitial</u>	Gets the value of initial margin
<u>MarginMaintenance</u>	Gets the value of maintenance margin

<u>MarginLong</u>	Gets the rate of margin charging for long positions
<u>MarginShort</u>	Gets the rate of margin charging for short positions
<u>MarginLimit</u>	Gets the rate of margin charging for Limit orders
<u>MarginStop</u>	Gets the rate of margin charging for Stop orders
<u>MarginStopLimit</u>	Gets the rate of margin charging for StopLimit orders
<u>TradeTimeFlags</u>	Gets the flags of allowed expiration modes
<u>TradeFillFlags</u>	Gets the flags of allowed filling modes
Quantization	
<u>Digits</u>	Gets the number of digits after period
<u>Point</u>	Gets the value of one point
<u>TickValue</u>	Gets the tick value (minimal change of price)
<u>TickValueProfit</u>	Gets the calculated tick price for a profitable position
<u>TickValueLoss</u>	Gets the calculated tick price for a losing position
<u>TickSize</u>	Gets the minimal change of price
Contracts sizes	
<u>ContractSize</u>	Gets the amount of trade contract
<u>LotsMin</u>	Gets the minimal volume to close a deal
<u>LotsMax</u>	Gets the maximal volume to close a deal
<u>LotsStep</u>	Gets the minimal step of volume change to close a deal
<u>LotsLimit</u>	Gets the maximal allowed volume of opened position and pending orders (direction insensitive) for one symbol
Swaps sizes	
<u>SwapLong</u>	Gets the value of long position swap
<u>SwapShort</u>	Gets the value of short position swap
Text properties	
<u>CurrencyBase</u>	Gets the name of symbol base currency

CurrencyProfit	Gets the profit currency name
CurrencyMargin	Gets the margin currency name
Bank	Gets the name of current quote source
Description	Gets the string description of symbol
Path	Gets the path in symbols tree
Symbol properties	
SessionDeals	Gets the number of deals in the current session
SessionBuyOrders	Gets the number of Buy orders at the moment
SessionSellOrders	Gets the number of Sell orders at the moment
SessionTurnover	Gets the summary of turnover of the current session
SessionInterest	Gets the summary of open interest of the current session
SessionBuyOrdersVolume	Gets the current volume of Buy orders
SessionSellOrdersVolume	Gets the current volume of Sell orders
SessionOpen	Gets the open price of the current session
SessionClose	Gets the close price of the current session
SessionAW	Gets the average weighted price of the current session
SessionPriceSettlement	Gets the settlement price of the current session
SessionPriceLimitMin	Gets the minimal price of the current session
SessionPriceLimitMax	Gets the maximal price of the current session
Access to MQL5 API functions	
InfoInteger	Gets the value of specified integer type property
InfoDouble	Gets the value of specified double type property
InfoString	Gets the value of specified string type property
Service functions	
NormalizePrice	Returns the value of price, normalized using the symbol properties

Methods inherited from class CObject

Prev, Prev, Next, Next, [Save](#), [Load](#), [Type](#), [Compare](#)

Refresh

Refreshes the symbol data.

```
void Refresh()
```

Return Value

None.

Note

The symbol should be selected by [Name](#) method.

RefreshRates

Refreshes the symbol quotes data.

```
bool RefreshRates ()
```

Return Value

true - success, false - unable to refresh quotes.

Note

The symbol should be selected by [Name](#) method.

Name

Gets symbol name.

```
string Name() const
```

Return Value

Symbol name.

Name

Sets symbol name.

```
bool Name(string name)
```

Return Value

None.

Select

Gets the "Market Watch" symbol flag.

```
bool Select() const
```

Return Value

"Market Watch" symbol flag.

Select

Sets the "Market Watch" symbol flag.

```
bool Select()
```

Return Value

true - success, false - unable to change flag.

Note

The symbol should be selected by [Name](#) method.

IsSynchronized

Checks the symbol synchronization with server.

```
bool IsSynchronized() const
```

Return Value

true - if the symbol is synchronized with server, false - if not.

Note

The symbol should be selected by [Name](#) method.

Volume

Gets the volume of last deal.

```
long Volume() const
```

Return Value

Volume of last deal.

Note

The symbol should be selected by [Name](#) method.

VolumeHigh

Gets the maximal volume of the day.

```
long VolumeHigh() const
```

Return Value

Maximal volume of the day.

Note

The symbol should be selected by [Name](#) method.

VolumeLow

Gets the minimal volume of the day.

```
long VolumeLow() const
```

Return Value

Minimal volume of the day.

Note

The symbol should be selected by [Name](#) method.

Time

Gets the time of last quote.

```
datetime Time() const
```

Return Value

Time of last quote.

Note

The symbol should be selected by [Name](#) method.

Spread

Gets the amount of spread (in points).

```
int Spread() const
```

Return Value

Gets the amount of spread (in points).

Note

The symbol should be selected by [Name](#) method.

SpreadFloat

Gets the flag of floating spread.

```
bool SpreadFloat() const
```

Return Value

Flag of floating spread.

Note

The symbol should be selected by [Name](#) method.

TicksBookDepth

Gets the depth of ticks saving.

```
int TicksBookDepth() const
```

Return Value

Depth of ticks saving.

Note

The symbol should be selected by [Name](#) method.

StopsLevel

Gets the minimal stop level for orders (in points).

```
int StopsLevel() const
```

Return Value

Minimal stop level for orders (in points).

Note

The symbol should be selected by [Name](#) method.

FreezeLevel

Gets the freeze level (in points).

```
int FreezeLevel() const
```

Return Value

Distance of freeze level (in points).

Note

The symbol should be selected by [Name](#) method.

Bid

Gets the current Bid price.

```
double Bid() const
```

Return Value

Current Bid price.

Note

The symbol should be selected by [Name](#) method.

BidHigh

Gets the maximal Bid price of the day.

```
double BidHigh() const
```

Return Value

Maximal Bid price of the day.

Note

The symbol should be selected by [Name](#) method.

BidLow

Gets the minimal Bid price of the day.

```
double BidLow() const
```

Return Value

Minimal Bid price of the day.

Note

The symbol should be selected by [Name](#) method.

Ask

Gets the current Ask price.

```
double Ask() const
```

Return Value

Current Ask price.

Note

The symbol should be selected by [Name](#) method.

AskHigh

Gets the maximal Ask price for a day.

```
double AskHigh() const
```

Return Value

Maximal Ask price of the day.

Note

The symbol should be selected by [Name](#) method.

AskLow

Gets the minimal Ask price for a day.

```
double AskLow() const
```

Return Value

Minimal Ask price of the day.

Note

The symbol should be selected by [Name](#) method.

Last

Gets the current Last price.

```
double Last() const
```

Return Value

Current Last price.

LastHigh

Gets the maximal Last price of the day.

```
double LastHigh() const
```

Return Value

Maximal Last price of the day.

Note

The symbol should be selected by [Name](#) method.

LastLow

Gets the minimal Last price of the day.

```
double LastLow() const
```

Return Value

Minimal Last price of the day.

Note

The symbol should be selected by [Name](#) method.

TradeCalcMode

Gets the mode of contract cost calculation.

```
ENUM_SYMBOL_CALC_MODE TradeCalcMode() const
```

Return Value

Mode of contract cost calculation from [ENUM_SYMBOL_CALC_MODE](#) enumeration.

Note

The symbol should be selected by [Name](#) method.

TradeCalcModeDescription

Gets the mode of contract cost calculation as a string.

```
string TradeCalcModeDescription() const
```

Return Value

Mode of contract cost calculation as a string.

Note

The symbol should be selected by [Name](#) method.

TradeMode

Gets the order execution type.

```
ENUM_SYMBOL_TRADE_MODE TradeMode() const
```

Return Value

Order execution type from [ENUM_SYMBOL_TRADE_MODE](#) enumeration.

Note

The symbol should be selected by [Name](#) method.

TradeModeDescription

Gets the trade mode as a string.

```
string TradeModeDescription() const
```

Return Value

Trade mode as a string.

Note

The symbol should be selected by [Name](#) method.

TradeExecution

Gets the trade execution mode.

```
ENUM_SYMBOL_TRADE_EXECUTION TradeExecution() const
```

Return Value

Trade execution mode from [ENUM_SYMBOL_TRADE_EXECUTION](#) enumeration.

Note

The symbol should be selected by [Name](#) method.

TradeExecutionDescription

Gets the description of trade execution mode as a string.

```
string TradeExecutionDescription() const
```

Return Value

Trade execution mode as a string.

Note

The symbol should be selected by [Name](#) method.

SwapMode

Gets the swap calculation mode.

```
ENUM_SYMBOL_SWAP_MODE SwapMode() const
```

Return Value

Swap calculation mode from [ENUM_SYMBOL_SWAP_MODE](#) enumeration.

Note

The symbol should be selected by [Name](#) method.

SwapModeDescription

Gets the swap mode description as a string.

```
string SwapModeDescription() const
```

Return Value

Swap mode description as a string.

Note

The symbol should be selected by [Name](#) method.

SwapRollover3days

Gets the swap rollover day.

```
ENUM_DAY_OF_WEEK SwapRollover3days () const
```

Return Value

Swap rollover day from [ENUM_DAY_OF_WEEK](#) enumeration.

Note

The symbol should be selected by [Name](#) method.

SwapRollover3daysDescription

Gets the swap rollover day as a string.

```
string SwapRollover3daysDescription() const
```

Return Value

Swap rollover day as a string.

Note

The symbol should be selected by [Name](#) method.

MarginInitial

Gets the value of initial margin.

```
double MarginInitial ()
```

Return Value

Value of initial margin.

Note

It returns the amount of margin (in margin currency of instrument) that is charged from one lot. Used to check client's equity, when they enter the market.

The symbol should be selected by [Name](#) method.

MarginMaintenance

Gets the value of maintenance margin.

```
double MarginMaintenance()
```

Return Value

Value of maintenance margin.

Note

It returns the amount of margin (in margin currency of instrument) that is charged from one lot. Used to check client's equity, when the account state is changed. If the maintenance margin is equal to 0, then the initial margin is used.

The symbol should be selected by [Name](#) method.

MarginLong

Gets the rate of margin charging on long positons.

```
double MarginLong() const
```

Return Value

Rate of margin charging on long positons.

Note

The symbol should be selected by [Name](#) method.

MarginShort

Gets the rate of margin charging on short positons.

```
double MarginShort() const
```

Return Value

Rate of margin charging on short positons.

Note

The symbol should be selected by [Name](#) method.

MarginLimit

Gets the rate of margin charging on Limit orders.

```
double MarginLimit() const
```

Return Value

Rate of margin charging on Limit orders.

Note

The symbol should be selected by [Name](#) method.

MarginStop

Gets the rate of margin charging on Stop orders.

```
double MarginStop() const
```

Return Value

Rate of margin charging on Stop orders.

Note

The symbol should be selected by [Name](#) method.

MarginStopLimit

Gets the rate of margin charging on Stop Limit orders.

```
double MarginStopLimit() const
```

Return Value

Rate of margin charging on Stop Limit orders.

Note

The symbol should be selected by [Name](#) method.

TradeTimeFlags

Gets the flags of allowed expiration modes.

```
int TradeTimeFlags() const
```

Return Value

Flags of allowed expiration modes.

Note

The symbol should be selected by [Name](#) method.

TradeFillFlags

Gets the flags of allowed filling modes.

```
int TradeFillFlags() const
```

Return Value

Flags of allowed filling modes.

Note

The symbol should be selected by [Name](#) method.

Digits

Gets the number of digits after period.

```
int Digits() const
```

Return Value

The number of digits after period.

Note

The symbol should be selected by [Name](#) method.

Point

Gets the value of one point.

```
double Point () const
```

Return Value

Value of one point.

Note

The symbol should be selected by [Name](#) method.

TickValue

Gets the tick value (minimal change of price).

```
double TickValue() const
```

Return Value

Tick value (minimal change of price).

Note

The symbol should be selected by [Name](#) method.

TickValueProfit

Gets the calculated tick price for a profitable position.

```
double TickValueProfit() const
```

Return Value

The calculated tick price for a profitable position.

Note

The symbol should be selected by [Name](#) method.

TickValueLoss

Gets the calculated tick price for a losing position.

```
double TickValueLoss () const
```

Return Value

The calculated tick price for a losing position.

Note

The symbol should be selected by [Name](#) method.

TickSize

Gets the minimal change of price.

```
double TickSize() const
```

Return Value

Minimal change of price.

Note

The symbol should be selected by [Name](#) method.

ContractSize

Gets the amount of trade contract.

```
double ContractSize() const
```

Return Value

Amount of trade contract.

Note

The symbol should be selected by [Name](#) method.

LotsMin

Gets the minimal volume to close a deal.

```
double LotsMin() const
```

Return Value

Minimal volume to close a deal.

Note

The symbol should be selected by [Name](#) method.

LotsMax

Gets the maximal volume to close a deal.

```
double LotsMax() const
```

Return Value

Maximal volume to close a deal.

Note

The symbol should be selected by [Name](#) method.

LotsStep

Gets the minimal step of volume change to close a deal.

```
double LotsStep() const
```

Return Value

Minimal step of volume change to close a deal.

Note

The symbol should be selected by [Name](#) method.

LotsLimit

Gets the maximal allowed volume of opened position and pending orders (direction insensitive) for one symbol.

```
double LotsLimit() const
```

Return Value

The maximal allowed volume of opened position and pending orders (direction insensitive) for one symbol.

Note

The symbol should be selected by [Name](#) method.

SwapLong

Gets the value of long position swap.

```
double SwapLong() const
```

Return Value

Value of long position swap.

Note

The symbol should be selected by [Name](#) method.

SwapShort

Gets the value of short position swap.

```
double SwapShort() const
```

Return Value

Value of short position swap.

Note

The symbol should be selected by [Name](#) method.

CurrencyBase

Gets the name of symbol base currency.

```
string CurrencyBase() const
```

Return Value

Name of symbol base currency.

Note

The symbol should be selected by [Name](#) method.

CurrencyProfit

Gets the profit currency name.

```
string CurrencyProfit() const
```

Return Value

Profit currency name.

Note

The symbol should be selected by [Name](#) method.

CurrencyMargin

Gets the margin currency name.

```
string CurrencyMargin() const
```

Return Value

Margin currency name.

Note

The symbol should be selected by [Name](#) method.

Bank

Gets the name of current quote source.

```
string Bank() const
```

Return Value

Name of current quote source.

Note

The symbol should be selected by [Name](#) method.

Description

Gets the string description of symbol.

```
string Description() const
```

Return Value

String description of symbol.

Note

The symbol should be selected by [Name](#) method.

Path

Gets the path in symbols tree.

```
string Path() const
```

Return Value

Gets the path in symbols tree.

Note

The symbol should be selected by [Name](#) method.

SessionDeals

Gets the number of deals in the current session.

```
long SessionDeals() const
```

Return Value

Number of deals in the current session.

Note

The symbol should be selected by [Name](#) method.

SessionBuyOrders

Gets the number of Buy orders at the moment.

```
long SessionBuyOrders() const
```

Return Value

Number of Buy orders at the moment.

Note

The symbol should be selected by [Name](#) method.

SessionSellOrders

Gets then number of Sell orders at the moment.

```
long SessionSellOrders() const
```

Return Value

Number of Sell orders at the moment.

Note

The symbol should be selected by [Name](#) method.

SessionTurnover

Gets summary turnover of the current session.

```
double SessionTurnover() const
```

Return Value

Summary turnover of the current session.

Note

The symbol should be selected by [Name](#) method.

SessionInterest

Gets the summary of open interest of the current session.

```
double SessionInterest() const
```

Return Value

Summary open interest of the current session.

Note

The symbol should be selected by [Name](#) method.

SessionBuyOrdersVolume

Gets the current volume of Buy orders.

```
double SessionBuyOrdersVolume () const
```

Return Value

Current volume of Buy orders.

Note

The symbol should be selected by [Name](#) method.

SessionSellOrdersVolume

Gets the current volume of Sell orders.

```
double SessionSellOrdersVolume() const
```

Return Value

Current volume of Sell orders.

Note

The symbol should be selected by [Name](#) method.

SessionOpen

Gets the open price of the current session.

```
double SessionOpen() const
```

Return Value

Open price of the current session.

Note

The symbol should be selected by [Name](#) method.

SessionClose

Gets the close price of the current session.

```
double SessionClose() const
```

Return Value

Close price of the current session.

Note

The symbol should be selected by [Name](#) method.

SessionAW

Gets the average weighted price of the current session.

```
double SessionAW() const
```

Return Value

Average weighted price of the current session.

Note

The symbol should be selected by [Name](#) method.

SessionPriceSettlement

Gets the settlement price of the current session.

```
double SessionPriceSettlement () const
```

Return Value

Settlement price of the current session.

Note

The symbol should be selected by [Name](#) method.

SessionPriceLimitMin

Gets the minimal price of the current session.

```
double SessionPriceLimitMin() const
```

Return Value

Minimal price of the current session.

Note

The symbol should be selected by [Name](#) method.

SessionPriceLimitMax

Gets the maximal price of the current session.

```
double SessionPriceLimitMax() const
```

Return Value

Maximal price of the current session.

Note

The symbol should be selected by [Name](#) method.

InfoInteger

Gets the value of specified integer type property.

```
bool InfoInteger (
    ENUM_SYMBOL_INFO_INTEGER prop_id,    // property ID
    long& var                             // reference to variable
) const
```

Parameters

prop_id

[in] ID of integer type property from [ENUM_SYMBOL_INFO_INTEGER](#) enumeration.

var

[out] Reference to [long](#) type variable to place result.

Return Value

true - success, false - unable to get property value.

Note

The symbol should be selected by [Name](#) method.

InfoDouble

Gets the value of specified double type property.

```
bool InfoDouble(  
    ENUM_SYMBOL_INFO_DOUBLE prop_id,    // property ID  
    double& var                        // reference to variable  
) const
```

Parameters

prop_id

[in] ID of double type property from [ENUM_SYMBOL_INFO_DOUBLE](#) enumeration.

var

[out] Reference to [double](#) type variable to place result.

Return Value

true - success, false - unable to get property value.

Note

The symbol should be selected by [Name](#) method.

InfoString

Gets the value of specified string type property.

```
bool InfoString(  
    ENUM_SYMBOL_INFO_STRING prop_id,    // property ID  
    string& var                        // reference to variable  
) const
```

Parameters

prop_id

[in] ID of text property.

var

[out] Reference to [string](#) type variable to place result.

Return Value

true - success, false - unable to get property value.

Note

The symbol should be selected by [Name](#) method.

NormalizePrice

Returns the value of price normalized using the symbol properties.

```
double NormalizePrice(  
    double price // price  
    ) const
```

Parameters

price

[in] Price.

Return Value

Normalized price.

Note

The symbol should be selected by [Name](#) method.

COrderInfo

COrderInfo is a class for easy access to the pending order properties.

Description

COrderInfo class provides access to the pending order properties.

Declaration

```
class COrderInfo : public CObject
```

Title

```
#include <Trade\OrderInfo.mqh>
```

Inheritance hierarchy

CObject

COrderInfo

Class methods by groups

Access to integer type properties	
<u>Ticket</u>	Gets the ticket of an order, previously selected for access
<u>TimeSetup</u>	Gets the time of order placement
<u>TimeSetupMsc</u>	Receives the time of placing an order in milliseconds since 01.01.1970
<u>OrderType</u>	Gets the order type
<u>OrderTypeDescription</u>	Gets the order type as a string
<u>State</u>	Gets the order state
<u>StateDescription</u>	Gets the order state as a string
<u>TimeExpiration</u>	Gets the time of order expiration
<u>TimeDone</u>	Gets the time of order execution or cancellation
<u>TimeDoneMsc</u>	Receives order execution or cancellation time in milliseconds since 01.01.1970
<u>TypeFilling</u>	Gets the type of order execution by remainder
<u>TypeFillingDescription</u>	Gets the type of order execution by remainder as a string
<u>TypeTime</u>	Gets the type of order at the time of the expiration

TypeTimeDescription	Gets the order type by expiration time as a string
Magic	Gets the ID of expert that placed the order
PositionId	Gets the ID of position
Access to double type properties	
VolumeInitial	Gets the initial volume of order
VolumeCurrent	Gets the unfilled volume of order
PriceOpen	Gets the order price
StopLoss	Gets the order's Stop Loss
TakeProfit	Gets the order's Take Profit
PriceCurrent	Gets the current price by order symbol
PriceStopLimit	Gets the price of a Limit order
Access to text properties	
Symbol	Gets the name of order symbol
Comment	Gets the order comment
Access to MQL5 API functions	
InfoInteger	Gets the value of specified integer type property
InfoDouble	Gets the value of specified double type property
InfoString	Gets value of specified string type property
State	
StoreState	Saves the order parameters
CheckState	Checks the current parameters against the saved parameters
Selection	
Select	Selects an order by ticket for further access to its properties
SelectByIndex	Selects an order by index for further access to its properties

Methods inherited from class CObject

Prev, Prev, Next, Next, [Save](#), [Load](#), [Type](#), [Compare](#)

Ticket

Gets the ticket of an order.

```
ulong Ticket () const
```

Return Value

Order ticket if successful, otherwise - [ULONG_MAX](#).

Note

The order should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

TimeSetup

Gets the time of order placement.

```
datetime TimeSetup() const
```

Return Value

Time of order placement.

Note

The order should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

TimeSetupMsc

Receives the time of placing an order for execution in milliseconds since 01.01.1970.

```
ulong TimeSetupMsc() const
```

Return Value

The time of placing an order for execution in milliseconds since 01.01.1970.

Note

Order should be preliminarily selected for access using [Select](#) (by ticket) or [SelectByIndex](#) (by index) method.

OrderType

Gets the order type.

```
ENUM_ORDER_TYPE OrderType()
```

Return Value

Order type from [ENUM_ORDER_TYPE](#) enumeration.

Note

The order should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

TypeDescription

Gets the order type as a string.

```
string TypeDescription() const
```

Return Value

Order type as a string.

Note

The order should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

State

Gets the order state.

```
ENUM_ORDER_STATE State() const
```

Return Value

Order state from [ENUM_ORDER_STATE](#) enumeration.

Note

The order should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

StateDescription

Gets the order state as a string.

```
string StateDescription() const
```

Return Value

Order state as a string.

Note

The order should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

TimeExpiration

Gets the order expiration time.

```
datetime TimeExpiration() const
```

Return Value

Order expiration time, set on its placement.

Note

The order should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

TimeDone

Gets the time of order execution or cancellation.

```
datetime TimeDone() const
```

Return Value

Time of order execution or cancellation.

Note

The order should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

TimeDoneMsc

Receives order execution or cancellation time in milliseconds since 01.01.1970.

```
ulong TimeDoneMsc() const
```

Return Value

Order execution or cancellation time in milliseconds since 01.01.1970.

Note

Order should be preliminarily selected for access using [Select](#) (by ticket) or [SelectByIndex](#) (by index) method.

TypeFilling

Gets the order filling type.

```
ENUM_ORDER_TYPE_FILLING TypeFilling() const
```

Return Value

Order filling type from [ENUM_ORDER_TYPE_FILLING](#) enumeration.

Note

The order should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

TypeFillingDescription

Gets the order filling type as a string.

```
string TypeFillingDescription() const
```

Return Value

Order filling type as a string.

Note

The order should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

TypeTime

Gets the type of order at the time of the expiration.

```
ENUM_ORDER_TYPE_TIME TypeTime () const
```

Return Value

Type of order at the time of the expiration from [ENUM_ORDER_TYPE_TIME](#) enumeration.

Note

The order should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

TypeTimeDescription

Gets the order type by expiration time as a string.

```
string TypeTimeDescription() const
```

Return Value

Order type by expiration time as a string.

Note

The order should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

Magic

Gets the ID of an Expert Advisor that placed the order.

```
long Magic() const
```

Return Value

ID of an Expert Advisor that placed the order.

Note

The order should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

PositionId

Gets the ID of position.

```
long PositionId() const
```

Return Value

ID of position, in which the order was involved.

Note

The order should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

VolumeInitial

Gets the initial volume of order.

```
double VolumeInitial () const
```

Return Value

Initial volume of order.

Note

The order should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

VolumeCurrent

Gets the unfilled volume of order.

```
double VolumeCurrent() const
```

Return Value

Unfilled volume of order.

Note

The order should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

PriceOpen

Gets the order price.

```
double PriceOpen() const
```

Return Value

Price of order placement.

Note

The order should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

StopLoss

Gets the order's Stop Loss.

```
double StopLoss() const
```

Return Value

Order's Stop Loss.

Note

The order should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

TakeProfit

Gets the order's Take Profit.

```
double TakeProfit() const
```

Return Value

Order's Take Profit.

Note

The order should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

PriceCurrent

Gets the current price by order symbol.

```
double PriceCurrent() const
```

Return Value

Current price by order symbol.

Note

The order should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

PriceStopLimit

Gets the price of a pending order.

```
double PriceStopLimit() const
```

Return Value

Pending order price.

Note

The order should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

Symbol

Gets the name of order symbol.

```
string Symbol() const
```

Return Value

Name of order symbol.

Note

The order should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

Comment

Gets the order comment.

```
string Comment() const
```

Return Value

Order comment.

Note

The order should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

InfoInteger

Gets the value of specified integer type property.

```
bool InfoInteger(  
    ENUM_ORDER_PROPERTY_INTEGER prop_id,    // property ID  
    long& var                                // reference to variable  
) const
```

Parameters

prop_id

[in] ID of integer type property from [ENUM_ORDER_PROPERTY_INTEGER](#) enumeration.

var

[out] Reference to [long](#) type variable to place result.

Return Value

true - success, false - unable to get property value.

Note

The order should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

InfoDouble

Gets the value of specified double type property.

```
bool  InfoDouble (
    ENUM_ORDER_PROPERTY_DOUBLE prop_id,    // property ID
    double&          var                   // reference to variable
) const
```

Parameters

prop_id

[in] ID of double type property from [ENUM_ORDER_PROPERTY_DOUBLE](#) enumeration.

var

[out] Reference to [double](#) type variable to place result.

Return Value

true - success, false - unable to get property value.

Note

The order should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

InfoString

Gets the value of specified string type property.

```
bool InfoString(  
    ENUM_ORDER_PROPERTY_STRING prop_id,    // property ID  
    string& var                            // reference to variable  
) const
```

Parameters

prop_id

[in] ID of string property from [ENUM_ORDER_PROPERTY_STRING](#) enumeration.

var

[out] Reference to [string](#) type variable to place result.

Return Value

true - success, false - unable to get property value.

Note

The order should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

StoreState

Saves the order parameters.

```
void StoreState()
```

Return Value

None.

CheckState

Checks the current parameters against the saved parameters.

```
bool CheckState()
```

Return Value

true - if the order parameters have changed since the last call of the [StoreState\(\)](#) method, otherwise
- false.

Select

Selects an order by ticket for further access to its properties.

```
bool Select(  
    ulong ticket // order ticket  
)
```

Return Value

true - success, false - unable to select order.

SelectByIndex

Selects an order by index.

```
bool SelectByIndex(  
    int index // order index  
)
```

Parameters

index

[in] Order index.

Return Value

true - success, false - unable to select order.

CHistoryOrderInfo

CHistoryOrderInfo is a class for easy access to the history order properties.

Description

CHistoryOrderInfo class provides easy access to the history order properties.

Declaration

```
class CHistoryOrderInfo : public CObject
```

Title

```
#include <Trade\HistoryOrderInfo.mqh>
```

Inheritance hierarchy

CObject

CHistoryOrderInfo

Class methods by groups

Access to integer type properties	
<u>TimeSetup</u>	Gets the time of order placement
<u>TimeSetupMsc</u>	Receives the time of placing an order in milliseconds since 01.01.1970
<u>OrderType</u>	Gets the order type
<u>OrderTypeDescription</u>	Gets the order type as a string
<u>State</u>	Gets the order state
<u>StateDescription</u>	Gets the order state as a string
<u>TimeExpiration</u>	Gets the time of order expiration
<u>TimeDone</u>	Gets the time of order execution or cancellation
<u>TimeDoneMsc</u>	Receives order execution or cancellation time in milliseconds since 01.01.1970
<u>TypeFilling</u>	Gets the type of order execution by remainder
<u>TypeFillingDescription</u>	Gets the type of order execution by remainder as a string
<u>TypeTime</u>	Gets the type of order at the time of the expiration
<u>TypeTimeDescription</u>	Gets the order type by expiration time as a string

Magic	Gets the ID of expert that placed the order
PositionId	Gets the ID of position
Access to double type properties	
VolumeInitial	Gets the initial volume of order
VolumeCurrent	Gets the unfilled volume of order
PriceOpen	Gets the order price
StopLoss	Gets the order's Stop Loss
TakeProfit	Gets the order's Take Profit
PriceCurrent	Gets the current price by order symbol
PriceStopLimit	Gets the price of a Limit order
Access to text properties	
Symbol	Gets the order symbol
Comment	Gets the order comment
Access to MQL5 API functions	
InfoInteger	Gets the value of specified integer type property
InfoDouble	Gets the value of specified double type property
InfoString	Gets value of specified string type property
Selection	
Ticket	Gets the ticket/selects the order
SelectByIndex	Selects the order by index

Methods inherited from class CObject

Prev, Prev, Next, Next, [Save](#), [Load](#), [Type](#), [Compare](#)

TimeSetup

Gets the time of order placement.

```
datetime TimeSetup() const
```

Return Value

Time of order placement.

Note

The historical order should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

TimeSetupMsc

Receives the time of placing an order for execution in milliseconds since 01.01.1970.

```
ulong TimeSetupMsc() const
```

Return Value

The time of placing an order for execution in milliseconds since 01.01.1970.

Note

Historical order should be preliminarily selected for access using [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) method.

OrderType

Gets the order type.

```
ENUM_ORDER_TYPE OrderType() const
```

Return Value

Order type from [ENUM_ORDER_TYPE](#) enumeration.

Note

The historical order should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

TypeDescription

Gets the order type as a string.

```
string TypeDescription() const
```

Return Value

Order type as a string.

Note

The historical order should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

State

Gets the order state.

```
ENUM_ORDER_STATE State() const
```

Return Value

Order state from [ENUM_ORDER_STATE](#) enumeration.

Note

The historical order should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

StateDescription

Gets the order state as a string.

```
string StateDescription() const
```

Return Value

Order state as a string.

Note

The historical order should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

TimeExpiration

Gets the time of order expiration.

```
datetime TimeExpiration() const
```

Return Value

Time of order expiration, set on its placement.

Note

The historical order should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

TimeDone

Gets the time of order execution or cancellation.

```
datetime TimeDone() const
```

Return Value

Time of order execution or cancellation.

Note

The historical order should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

TimeDoneMsc

Receives order execution or cancellation time in milliseconds since 01.01.1970.

```
ulong TimeDoneMsc() const
```

Return Value

Order execution or cancellation time in milliseconds since 01.01.1970.

Note

Historical order should be preliminarily selected for access using [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) method.

TypeFilling

Gets the type of order execution by remainder.

```
ENUM_ORDER_TYPE_FILLING TypeFilling() const
```

Return Value

Type of order execution by remainder from [ENUM_ORDER_TYPE_FILLING](#) enumeration.

Note

The historical order should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

TypeFillingDescription

Gets the type of order execution by remainder as a string.

```
string TypeFillingDescription() const
```

Return Value

Type order of execution by remainder as a string.

Note

The historical order should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

TypeTime

Gets the type of order at the time of the expiration.

```
ENUM_ORDER_TYPE_TIME TypeTime () const
```

Return Value

Type of order at the time of the expiration from [ENUM_ORDER_TYPE_TIME](#) enumeration.

Note

The historical order should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

TypeTimeDescription

Gets the order type by expiration time as a string.

```
string TypeTimeDescription() const
```

Return Value

Order type by expiration time as a string.

Note

The historical order should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

Magic

Gets the ID of the Expert Advisor, that placed the order.

```
long Magic() const
```

Return Value

ID of the Expert Advisor, that placed the order.

Note

The historical order should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

PositionId

Gets the ID of position.

```
long PositionId() const
```

Return Value

ID of position, in which the order was involved.

Note

The historical order should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

VolumeInitial

Gets the initial volume of order.

```
double VolumeInitial () const
```

Return Value

Initial volume of order.

Note

The historical order should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

VolumeCurrent

Gets the unfilled volume of order.

```
double VolumeCurrent () const
```

Return Value

Unfilled volume of order.

Note

The historical order should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

PriceOpen

Gets the order price.

```
double PriceOpen() const
```

Return Value

Price of order placement.

Note

The historical order should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

StopLoss

Gets the Stop Loss price of the order.

```
double StopLoss() const
```

Return Value

Stop Loss price of the order.

Note

The historical order should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

TakeProfit

Gets the Take Profit price of the order.

```
double TakeProfit() const
```

Return Value

The Take Profit price of the order.

Note

The historical order should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

PriceCurrent

Gets the current price of the order's symbol.

```
double PriceCurrent() const
```

Return Value

The current price of order's symbol.

Note

The historical order should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

PriceStopLimit

Gets the pending order price.

```
double PriceStopLimit() const
```

Return Value

Pending orders price.

Note

The historical order should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

Symbol

Gets the name of order symbol.

```
string Symbol() const
```

Return Value

Name of order symbol.

Note

The historical order should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

Comment

Gets the order comment.

```
string Comment() const
```

Return Value

Order comment.

Note

The historical order should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

InfoInteger

Gets the value of specified integer type property.

```
bool InfoInteger (
    ENUM_ORDER_PROPERTY_INTEGER prop_id,    // property ID
    long& var                                // reference to variable
) const
```

Parameters

prop_id

[in] ID of integer type property from [ENUM_ORDER_PROPERTY_INTEGER](#) enumeration.

var

[out] Reference to [long](#) type variable to place result.

Return Value

true - success, false - unable to get property value.

Note

The historical order should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

InfoDouble

Gets the value of specified double type property.

```
bool InfoDouble(  
    ENUM_ORDER_PROPERTY_DOUBLE prop_id,    // property ID  
    double& var                            // reference to variable  
) const
```

Parameters

prop_id

[in] ID of double type property from [ENUM_ORDER_PROPERTY_DOUBLE](#) enumeration.

var

[out] Reference to [double](#) type variable to place result.

Return Value

true - success, false - unable to get property value.

Note

The historical order should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

InfoString

Gets the value of specified string type property.

```
bool InfoString(  
    ENUM_ORDER_PROPERTY_STRING prop_id,    // property ID  
    string& var                            // reference to variable  
) const
```

Parameters

prop_id

[in] ID of text property from [ENUM_ORDER_PROPERTY_STRING](#) enumeration.

var

[out] Reference to [string](#) type variable to place result.

Return Value

true - success, false - unable to get property value.

Note

The historical order should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

Ticket (Get method)

Gets the order ticket.

```
ulong Ticket() const
```

Return Value

Order ticket.

Ticket (Set method)

Select the order for further work.

```
void Ticket(  
    ulong ticket    // ticket  
)
```

Parameters

ticket

[in] Order ticket.

SelectByIndex

Selects a historical order by index.

```
bool SelectByIndex(  
    int index // order index  
)
```

Parameters

index

[in] Historical order index.

Return Value

true - success, false - unable to select order.

CPositionInfo

CPositionInfo is a class for easy access to the open position properties.

Description

CPositionInfo class provides easy access to the open position properties.

Declaration

```
class CPositionInfo : public CObject
```

Title

```
#include <Trade\PositionInfo.mqh>
```

Inheritance hierarchy

[CObject](#)

CPositionInfo

Class methods by groups

Access to integer type properties	
Time	Gets the time of position opening
TimeMsc	Receives the time of position opening in milliseconds since 01.01.1970
TimeUpdate	Receives the time of position changing in seconds since 01.01.1970
TimeUpdateMsc	Receives the time of position changing in milliseconds since 01.01.1970
PositionType	Gets the position type
TypeDescription	Gets the position type as a string
Magic	Gets the ID of expert, that opened the position
Identifier	Gets the ID of position
Access to double type properties	
Volume	Gets the volume of position
PriceOpen	Gets the price of position opening
StopLoss	Gets the price of position's Stop Loss
TakeProfit	Gets the price of position's Take Profit
PriceCurrent	Gets the current price by position symbol
Commission	Gets the amount of commission by position

Swap	Gets the amount of swap by position
Profit	Gets the amount of current profit by position
Access to text properties	
Symbol	Gets the name of position symbol
Comment	Gets the comment of the position
Access to MQL5 API functions	
InfoInteger	Gets the value of specified integer type property
InfoDouble	Gets the value of specified double type property
InfoString	Gets the value of specified string type property
Selection	
Select	Selects the position
SelectByIndex	Selects the position by index
SelectByMagic	Selects a position with the specified symbol name and magic number
SelectByTicket	Selects the position by ticket
State	
StoreState	Saves the position parameters
CheckState	Checks the current parameters against the saved parameters

Methods inherited from class CObject

Prev, Prev, Next, Next, [Save](#), [Load](#), [Type](#), [Compare](#)

Time

Gets the time of position opening.

```
datetime Time() const
```

Return Value

Time of position opening.

Note

The position should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

TimeMsc

Receives position opening time in milliseconds since 01.01.1970.

```
ulong TimeMsc() const
```

Return Value

Position opening time in milliseconds since 01.01.1970.

Note

Position should be preliminarily selected for access using [Select](#) (by symbol) or [SelectByIndex](#) (by index) method.

TimeUpdate

Receives the time of position changing in seconds since 01.01.1970.

```
datetime TimeUpdate() const
```

Return Value

Time of position changing in seconds since 01.01.1970.

Note

Position should be preliminarily selected for access using [Select](#) (by symbol) or [SelectByIndex](#) (by index) method.

TimeUpdateMsc

Receives the time of position changing in milliseconds since 01.01.1970.

```
ulong TimeUpdateMsc() const
```

Return Value

The time of position changing in milliseconds since 01.01.1970.

Note

Position should be preliminarily selected for access using [Select](#) (by symbol) or [SelectByIndex](#) (by index) method.

PositionType

Gets the position type.

```
ENUM_POSITION_TYPE PositionType() const
```

Return Value

Position type from [ENUM_POSITION_TYPE](#) enumeration.

Note

The position should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

TypeDescription

Gets the position type as a string.

```
string TypeDescription() const
```

Return Value

Position type as a string.

Note

The position should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

Magic

Gets the ID of Expert Advisor that opened the position.

```
long Magic() const
```

Return Value

ID of the Expert Advisor that opened the position.

Note

The position should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

Identifier

Gets the ID of position.

```
long Identifier() const
```

Return Value

ID of position.

Note

The position should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

Volume

Gets the volume of position.

```
double Volume() const
```

Return Value

Volume of position.

Note

The position should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

PriceOpen

Gets the price of position opening.

```
double PriceOpen() const
```

Return Value

Position open price.

Note

The position should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

StopLoss

Gets the Stop Loss price of the position.

```
double StopLoss() const
```

Return Value

The Stop Loss price of the position.

Note

The position should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

TakeProfit

Gets the Take Profit price of the position.

```
double TakeProfit() const
```

Return Value

The Take Profit price of the position.

Note

The position should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

PriceCurrent

Gets the current price by position symbol.

```
double PriceCurrent() const
```

Return Value

Current price by position symbol.

Note

The position should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

Commission

Gets the amount of commission of the position.

```
double Commission() const
```

Return Value

Amount of commission of the position (in deposit currency).

Note

The position should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

Swap

Gets the amount of swap of the position.

```
double Swap() const
```

Return Value

Amount of swap of the position (in deposit currency).

Note

The position should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

Profit

Gets the amount of current profit of the position.

```
double Profit() const
```

Return Value

Amount of current profit of the position (in deposit currency).

Note

The position should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

Symbol

Gets the name of position symbol.

```
string Symbol() const
```

Return Value

Name of position symbol.

Note

The position should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

Comment

Gets the comment of the position.

```
string Comment() const
```

Return Value

Comment of the position.

Note

The position should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

InfoInteger

Gets the value of specified integer type property.

```
bool InfoInteger(  
    ENUM_POSITION_PROPERTY_INTEGER prop_id,    // property ID  
    long& var                                // reference to variable  
) const
```

Parameters

prop_id

[in] ID of integer type property from [ENUM_POSITION_PROPERTY_INTEGER](#) enumeration.

var

[out] Reference to [long](#) type variable to place result.

Return Value

true - success, false - unable to get property value.

Note

The position should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

InfoDouble

Gets the value of specified double type property.

```
bool InfoDouble(  
    ENUM_POSITION_PROPERTY_DOUBLE prop_id,    // property ID  
    double& var                               // reference to variable  
) const
```

Parameters

prop_id

[in] ID of double type property from [ENUM_POSITION_PROPERTY_DOUBLE](#) enumeration.

var

[in] Reference to [double](#) type variable to place result.

Return Value

true - success, false - unable to get property value.

Note

The position should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

InfoString

Gets the value of specified string type property.

```
bool InfoString(  
    ENUM_POSITION_PROPERTY_STRING prop_id,    // property ID  
    string& var                               // reference to variable  
) const
```

Parameters

prop_id

[in] ID of text property from [ENUM_POSITION_PROPERTY_STRING](#) enumeration.

var

[out] Reference to [string](#) type variable to place result.

Return Value

true - success, false - unable to get property value.

Note

The position should be selected using the [Select](#) (by ticket) or [SelectByIndex](#) (by index) methods.

Select

Select the position for further work.

```
bool Select(  
    const string symbol      // symbol  
)
```

Parameters

symbol

[in] Symbol for position selection.

SelectByIndex

Selects the position by index for further access to its properties.

```
bool SelectByIndex(  
    int index // position index  
);
```

Return Value

true - success, false - unable to select position.

SelectByMagic

Select a position based on the name of a financial instrument and magic number to further work with.

```
bool SelectByMagic(  
    const string symbol, // symbol name  
    const ulong magic    // magic number  
);
```

Parameters

symbol

[in] Symbol name.

magic

[in] Magic number of the position.

Return Value

true - successful, false - unable to select position.

SelectByTicket

Selects position by ticket for further operation.

```
bool SelectByTicket(  
    ulong ticket    // position ticket  
);
```

Parameters

ticket

[in] Position ticket.

Return value

true - success, false - no position selected.

StoreState

Saves the position parameters.

```
void StoreState()
```

Return Value

None.

CheckState

Checks the current parameters against the saved parameters.

```
bool CheckState()
```

Return Value

true - the position parameters have changed since the last call of the [StoreState\(\)](#) method,
otherwise - false.

CDealInfo

CDealInfo is a class for easy access to the deal properties.

Description

CDealInfo class provides access to the deal properties.

Declaration

```
class CDealInfo : public CObject
```

Title

```
#include <Trade\DealInfo.mqh>
```

Inheritance hierarchy

CObject

CDealInfo

Class methods by groups

Access to integer type properties	
<u>Order</u>	Gets the order by which the deal is executed
<u>Time</u>	Gets the time of deal execution
<u>TimeMsc</u>	Receives the time of a deal execution in milliseconds since 01.01.1970
<u>DealType</u>	Gets the deal type
<u>TypeDescription</u>	Gets the deal type as a string
<u>Entry</u>	Gets the deal direction
<u>EntryDescription</u>	Gets the deal direction as a string
<u>Magic</u>	Gets the ID of expert, that executed the deal
<u>PositionId</u>	Gets the ID of position, in which the deal was involved
Access to double type properties	
<u>Volume</u>	Gets the volume of deal
<u>Price</u>	Gets the deal price
<u>Commision</u>	Gets the amount of commission of the deal
<u>Swap</u>	Gets the amount of swap when position is closed
<u>Profit</u>	Gets the financial result of deal

Access to text properties	
Symbol	Gets the name of deal symbol
Comment	Gets the deal comment
Access to MQL5 API functions	
InfoInteger	Gets the value of specified integer type property
InfoDouble	Gets the value of specified double type property
InfoString	Gets value of specified string type property
Selection	
Ticket	Gets ticket/selects the deal
SelectByIndex	Selects the deal by index

Methods inherited from class CObject

Prev, Prev, Next, Next, [Save](#), [Load](#), [Type](#), [Compare](#)

Order

Gets the order by which the deal is executed.

```
long Order() const
```

Return Value

Order by which the deal is executed.

Note

The deal should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

Time

Gets the time of deal execution.

```
datetime Time() const
```

Return Value

Time of deal execution.

Note

The deal should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

TimeMsc

Receives the time of a deal execution in milliseconds since 01.01.1970.

```
ulong TimeMsc() const
```

Return Value

The time of a deal execution in milliseconds since 01.01.1970.

Note

Deal should be preliminarily selected for access using [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) method.

DealType

Gets the deal type.

```
ENUM_DEAL_TYPE DealType() const
```

Return Value

Deal type from [ENUM_DEAL_TYPE](#) enumeration.

Note

The deal should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

TypeDescription

Gets the deal type as a string.

```
string TypeDescription() const
```

Return Value

Deal type as a string.

Note

The deal should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

Entry

Compares the deal direction.

```
ENUM_DEAL_ENTRY Entry() const
```

Return Value

Deal direction (value of [ENUM_DEAL_ENTRY](#) enumeration).

Note

The deal should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

EntryDescription

Gets the deal direction as a string.

```
string EntryDescription() const
```

Return Value

Deal direction as a string.

Note

The deal should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

Magic

Gets the ID of the Expert Advisor, that executed the deal.

```
long Magic() const
```

Return Value

ID of the Expert Advisor, that executed the deal.

Note

The deal should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

PositionId

Gets the ID of position, in which the deal was involved.

```
long PositionId() const
```

Return Value

ID of position, in which the deal was involved.

Note

The deal should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

Volume

Gets the volume of deal.

```
double Volume() const
```

Return Value

Volume of deal.

Note

The deal should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

Price

Gets the deal price.

```
double Price() const
```

Return Value

Deal price.

Note

The deal should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

Commission

Gets the amount of commission of the deal.

```
double Commission() const
```

Return Value

Amount of commission of the deal.

Note

The deal should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

Swap

Gets the amount of swap when position is closed.

```
double Swap() const
```

Return Value

Amount of swap when position is closed.

Note

The deal should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

Profit

Gets the financial result of the deal.

```
double Profit() const
```

Return Value

Financial result of the deal (in deposit currency).

Note

The deal should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

Symbol

Gets the name of the deal symbol.

```
string Symbol() const
```

Return Value

Name of the deal symbol.

Note

The deal should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

Comment

Gets the deal comment.

```
string Comment() const
```

Return Value

Deal comment.

Note

The deal should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

InfoInteger

Gets the value of specified integer type property.

```
bool InfoInteger (
    ENUM_DEAL_PROPERTY_INTEGER prop_id,    // property ID
    long& var                               // reference to variable
) const
```

Parameters

prop_id

[in] ID of integer type property from [ENUM_DEAL_PROPERTY_INTEGER](#) enumeration.

var

[out] Reference to [long](#) type variable to place result.

Return Value

true - success, false - unable to get property value.

Note

The deal should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

InfoDouble

Gets the value of specified double type property.

```
bool InfoDouble(  
    ENUM_DEAL_PROPERTY_DOUBLE prop_id,    // property ID  
    double& var                          // reference to variable  
) const
```

Parameters

prop_id

[in] ID of double type property from [ENUM_DEAL_PROPERTY_DOUBLE](#) enumeration.

var

[out] Reference to [double](#) type variable to place result.

Return Value

true - success, false - unable to get property value.

Note

The deal should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

InfoString

Gets the value of specified string type property.

```
bool InfoString(  
    ENUM_DEAL_PROPERTY_STRING prop_id,    // property ID  
    string& var                            // reference to variable  
) const
```

Parameters

prop_id

[in] ID of text property from [ENUM_DEAL_PROPERTY_STRING](#) enumeration.

var

[out] Reference to [string](#) type variable to place result.

Return Value

true - success, false - unable to get property value.

Note

The deal should be selected using the [Ticket](#) (by ticket) or [SelectByIndex](#) (by index) methods.

Ticket (Get method)

Gets the deal ticket.

```
ulong Ticket() const
```

Return Value

Deal ticket.

Ticket (Set method)

Select the position for further work.

```
void Ticket(  
    ulong ticket    // ticket  
)
```

Parameters

ticket

[in] Deal ticket.

SelectByIndex

Selects the deal by index for further access to its properties.

```
bool SelectByIndex(  
    int index // order index  
)
```

Return Value

true - success, false - unable to select the deal.

CTrade

CTrade is a class for easy access to the trade functions.

Description

CTrade class provides easy access to the trade functions.

Declaration

```
class CTrade : public CObject
```

Title

```
#include <Trade\Trade.mqh>
```

Inheritance hierarchy

[CObject](#)

CTrade

Direct descendants

CExpertTrade

Class methods by groups

Setting parameters	
LogLevel	Sets logging level
SetExpertMagicNumber	Sets the expert ID
SetDeviationInPoints	Sets the allowed deviation
SetTypeFilling	Sets filling type of the order
SetAsyncMode	Sets asynchronous mode for trade operations
SetMarginMode	Sets margin calculation mode in accordance with the current account settings
Operations with orders	
OrderOpen	Places a pending order with specified parameters
OrderModify	Modifies the pending order parameters
OrderDelete	Deletes a pending order
Operations with positions	
PositionOpen	Opens a position with specified parameters
PositionModify	Modifies position parameters by the specified symbol or position ticket

<u>PositionClose</u>	Closes a position for the specified symbol
<u>PositionClosePartial</u>	Partially closes a position on a specified symbol or having a specified ticket
<u>PositionCloseBy</u>	Closes a position with the specified ticket by an opposite position
Additional methods	
<u>Buy</u>	Opens a long position with specified parameters
<u>Sell</u>	Opens a short position with specified parameters
<u>BuyLimit</u>	Places a pending order of the Buy Limit type with specified parameters
<u>BuyStop</u>	Places a pending order of the Buy Stop type with specified parameters
<u>SellLimit</u>	Places a pending order of the Sell Limit type with specified parameters
<u>SellStop</u>	Places a pending order of the Sell Stop type with specified parameters
Access to the last request parameters	
<u>Request</u>	Gets the copy of the last request structure
<u>RequestAction</u>	Gets the trade operation type
<u>RequestActionDescription</u>	Gets the trade operation type as string
<u>RequestMagic</u>	Gets the magic number of the Expert Advisor
<u>RequestOrder</u>	Gets the order ticket used in the last request
<u>RequestSymbol</u>	Gets the name of the symbol used in the last request
<u>RequestVolume</u>	Gets the trade volume (in lots) used in the last request
<u>RequestPrice</u>	Gets the price used in the last request
<u>RequestStopLimit</u>	Gets the price of pending order of Stop Limit type used in the last request
<u>RequestSL</u>	Gets the Stop Loss price of the order used in the last request
<u>RequestTP</u>	Gets the Take Profit price of the order used in the last request
<u>RequestDeviation</u>	Gets the maximum allowable price deviation of the order used in the last request

<u>RequestType</u>	Gets the type of the order used in the last request
<u>RequestTypeDescription</u>	Gets the type of the order (as string) used in the last request
<u>RequestTypeFilling</u>	Gets the filling type of the order used in the last request
<u>RequestTypeFillingDescription</u>	Gets the filling type of the order (as string) used in the last request
<u>RequestTypeTime</u>	Gets the validity period of the order used in the last request
<u>RequestTypeTimeDescription</u>	Gets the validity period of the order (as string) used in the last request
<u>RequestExpiration</u>	Gets the expiration time of the order used in the last request
<u>RequestComment</u>	Gets the comment of the order used in the last request
<u>RequestPosition</u>	Gets position ticket
<u>RequestPositionBy</u>	Gets opposite position ticket
Access to the last request checking results	
<u>CheckResult</u>	Gets the copy of the structure of the last request check result.
<u>CheckResultRetcode</u>	Gets the value of the retcode field of <u>MqlTradeCheckResult</u> type, filled while checking the request correctness
<u>CheckResultRetcodeDescription</u>	Gets the string description of the retcode field of <u>MqlTradeCheckResult</u> type, filled while checking the request correctness
<u>CheckResultBalance</u>	Gets the value of the balance field of <u>MqlTradeCheckResult</u> type, filled while checking the request correctness
<u>CheckResultEquity</u>	Gets the value of the equity field of <u>MqlTradeCheckResult</u> type, filled while checking the request correctness
<u>CheckResultProfit</u>	Gets the value of the floating profit after executing a trading operation.
<u>CheckResultMargin</u>	Gets the value of the margin field of <u>MqlTradeCheckResult</u> type, filled while checking the request correctness

<u>CheckResultMarginFree</u>	Gets the value of the margin_free field of <u>MqlTradeCheckResult</u> type, filled while checking the request correctness
<u>CheckResultMarginLevel</u>	Gets the value of the margin_level field of <u>MqlTradeCheckResult</u> type, filled while checking the request correctness
<u>CheckResultComment</u>	Gets the value of the comment field of <u>MqlTradeCheckResult</u> type, filled while checking the request correctness
Access to the last request execution results	
<u>Result</u>	Gets the copy of the structure of the last request result
<u>ResultRetcode</u>	Gets the code of request result
<u>ResultRetcodeDescription</u>	Gets the code of request result as a string
<u>ResultDeal</u>	Gets the deal ticket
<u>ResultOrder</u>	Gets the order ticket
<u>ResultVolume</u>	Gets the volume of deal or order
<u>ResultPrice</u>	Gets the price, confirmed by broker
<u>ResultBid</u>	Gets the current bid price (the requote)
<u>ResultAsk</u>	Gets the current ask price (the requote)
<u>ResultComment</u>	Gets the broker comment
Auxiliary methods	
<u>PrintRequest</u>	Prints the last request parameters into journal
<u>PrintResult</u>	Prints the results of the last request into journal
<u>FormatRequest</u>	Prepares the formatted string with last request parameters
<u>FormatRequestResult</u>	Prepares the formatted string with results of the last request execution

Methods inherited from class CObject

Prev, Prev, Next, Next, [Save](#), [Load](#), [Type](#), [Compare](#)

LogLevel

Sets logging level for messages.

```
void LogLevel(  
    ENUM_LOG_LEVELS log_level    // level  
)
```

Parameters

log_level

[in] New logging level.

Return Value

None.

Note

LOG_LEVEL_NO and less disables displaying any messages (set up automatically in the optimization mode). LOG_LEVEL_ERRORS enables displaying only error messages (value by default). LOG_LEVEL_ALL and greater enables displaying any messages (set up automatically in the test mode).

ENUM_LOG_LEVELS

Identifier	Description	Value
LOG_LEVEL_NO	Displaying messages disabled	0
LOG_LEVEL_ERRORS	Only error messages are displayed	1
LOG_LEVEL_ALL	All messages are displayed	2

SetExpertMagicNumber

Sets the expert ID.

```
void SetExpertMagicNumber (
    ulong magic    // ID
)
```

Parameters

magic

[in] New ID of the expert.

Return Value

None.

SetDeviationInPoints

Sets the allowed deviation.

```
void SetDeviationInPoints(  
    ulong deviation    // deviation  
)
```

Parameters

deviation

[in] Allowed deviation in points.

Return Value

None.

SetTypeFilling

Sets filling type of the order.

```
void SetTypeFilling(  
    ENUM_ORDER_TYPE_FILLING filling    // order filling type  
)
```

Parameters

filling

[in] Order filling type from [ENUM_ORDER_TYPE_FILLING](#) enumeration.

Return Value

None.

SetAsyncMode

Sets asynchronous mode for trade operations.

```
void SetAsyncMode(  
    bool mode    // asynchronous mode flag  
)
```

Parameters

mode

[in] Asynchronous mode flag.

Return Value

None.

Note

This mode is used for asynchronous (without waiting for the trade server's response to a sent request) trade operations (see [OrderSendAsync](#)).

SetMarginMode

Sets margin calculation mode in accordance with the current account settings.

```
void SetMarginMode ()
```

Return Value

No.

Note

The margin calculation mode is specified in [ENUM_ACCOUNT_MARGIN_MODE](#).

OrderOpen

Places the pending order with set parameters.

```
bool OrderOpen(
    const string      symbol,           // symbol
    ENUM_ORDER_TYPE   order_type,      // order type
    double            volume,          // order volume
    double            limit_price,      // StopLimit price
    double            price,           // execution price
    double            sl,              // Stop Loss price
    double            tp,              // Take Profit price
    ENUM_ORDER_TYPE_TIME type_time,     // type by expiration
    datetime          expiration,      // expiration
    const string      comment=""       // comment
)
```

Parameters

symbol

[in] Name of trade instrument.

order_type

[in] Type of order trade operation from [ENUM_ORDER_TYPE](#) enumeration.

volume

[in] Requested order volume.

limit_price

[in] Price at which the StopLimit order will be placed.

price

[in] Price at which the order must be executed.

sl

[in] Price at which the Stop Loss will trigger.

tp

[in] Price at which the Take Profit will trigger.

type_time

[in] Order type by execution from [ENUM_ORDER_TYPE_TIME](#) enumeration.

expiration

[in] Expiration date of pending order.

comment=""

[in] Order comment.

Return Value

true - successful check of the basic structures, otherwise - false.

Note

Successful completion of the `OrderSend(...)` method does not always mean successful execution of the trade operation. It is necessary to check the result of a trade request (trade server return code) using [ResultRetcode\(\)](#) and value returned by [ResultOrder\(\)](#).

OrderModify

Modifies the pending order parameters.

```
bool OrderModify(
    ulong          ticket,          // order ticket
    double         price,           // execution price
    double         sl,              // Stop Loss price
    double         tp,              // Take Profit price
    ENUM_ORDER_TYPE_TIME type_time, // type by expiration
    datetime       expiration,      // expiration
    double         stoplimit        // Limit order price
)
```

Parameters

ticket

[in] Order ticket.

price

[in] The new price by which the order must be executed (or the previous value, if the change is not necessary).

sl

[in] The new price by which the Stop Loss will trigger (or the previous value, if the change is not necessary).

tp

[in] The new price by which the Take Profit will trigger (or the previous value, if the change is not necessary).

type_time

[in] The new type of order by expiration from [ENUM_ORDER_TYPE_TIME](#) enumeration (or the previous value, if the change is not necessary).

expiration

[in] The new expiration date of pending order (or the previous value, if the change is not necessary).

stoplimit

[in] New price used for setting a Limit order when the price reaches *price* value. It is specified only for StopLimit orders.

Return Value

true - successful check of the basic structures, otherwise - false.

Note

Successful completion of the OrderModify(...) method does not always mean successful execution of the trade operation. It is necessary to check the result of trade request (trade server return code) using [ResultRetcode\(\)](#).

OrderDelete

Deletes the pending order.

```
bool OrderDelete(  
    ulong ticket    // order ticket  
)
```

Parameters

ticket

[in] Order ticket.

Return Value

true - successful check of the basic structures, otherwise - false.

Note

Successful completion of the OrderDelete(...) method does not always mean successful execution of the trade operation. It is necessary to check the result of trade request (trade server return code) using [ResultRetcode\(\)](#).

PositionOpen

Opens a position with the specified parameters.

```
bool PositionOpen(  
    const string      symbol,           // symbol  
    ENUM_ORDER_TYPE  order_type,       // order type to open position  
    double            volume,           // position volume  
    double            price,            // execution price  
    double            sl,               // Stop Loss price  
    double            tp,               // Take Profit price  
    const string      comment=""        // comment  
)
```

Parameters

symbol

[in] Name of trade instrument, by which it is intended to open position.

order_type

[in] Order type (trade operation) to open position from [ENUM_ORDER_TYPE](#) enumeration.

volume

[in] Requested position volume.

price

[in] Price at which the position must be opened.

sl

[in] Price at which the Stop Loss will trigger.

tp

[in] Price at which the Take Profit will trigger.

comment=""

[in] Position comment.

Return Value

true - successful check of the basic structures, otherwise - false.

Note

Successful completion of the `PositionOpen(...)` method does not always mean successful execution of the trade operation. It is necessary to check the result of trade request (trade server return code) using [ResultRetcode\(\)](#) and value returned by [ResultDeal\(\)](#).

PositionModify

Modifies the position parameters by specified symbol.

```
bool PositionModify(  
    const string  symbol,      // symbol  
    double        sl,         // Stop Loss price  
    double        tp          // Take Profit price  
)
```

Modifies position parameters by the specified ticket.

```
bool PositionModify(  
    const ulong   ticket,      // position ticket  
    double        sl,         // Stop Loss price  
    double        tp          // Take Profit price  
)
```

Parameters

symbol

[in] Name of trade instrument, by which it is intended to modify position.

ticket

[in] Ticket of the position to be modified.

sl

[in] The new price by which the Stop Loss will trigger (or the previous value, if the change is not necessary).

tp

[in] The new price by which the Take Profit will trigger (or the previous value, if the change is not necessary).

Return Value

true - successful check of the basic structures, otherwise - false.

Note

Successful completion of the PositionModify(...) method does not always mean successful execution of the trade operation. It is necessary to check the result of trade request (trade server return code) using [ResultRetcode\(\)](#).

For the "netting" interpretation of positions ([ACCOUNT MARGIN MODE RETAIL NETTING](#) and [ACCOUNT MARGIN MODE EXCHANGE](#)), only one [position](#) can exist for a [symbol](#) at any moment of time. This position is a result of one or more [deals](#). Do not confuse positions with valid [pending orders](#), which are also displayed on the Trading tab of the Toolbox window.

If individual positions are allowed ([ACCOUNT MARGIN MODE RETAIL HEDGING](#)), multiple positions can be open for one symbol. In this case, PositionModify will modify the position with the lowest ticket.

PositionClose

Closes a position by the specified symbol.

```
bool PositionClose(  
    const string  symbol,           // symbol  
    ulong        deviation=ULONG_MAX // deviation  
)
```

Closes a position with the specified ticket.

```
bool PositionClose(  
    const ulong   ticket,           // position ticket  
    ulong        deviation=ULONG_MAX // deviation  
)
```

Parameters

symbol

[in] Name of trade instrument, by which it is intended to close position.

ticket

[in] Ticket of a closed position.

deviation=ULONG_MAX

[in] Maximal deviation from the current price (in points).

Return Value

true - successful check of the basic structures, otherwise - false.

Note

Successful completion of the PositionClose(...) method does not always mean successful execution of the trade operation. It is necessary to check the result of trade request (trade server return code) using [ResultRetcode\(\)](#).

For the "netting" interpretation of positions ([ACCOUNT_MARGIN_MODE_RETAIL_NETTING](#) and [ACCOUNT_MARGIN_MODE_EXCHANGE](#)), only one [position](#) can exist for a [symbol](#) at any moment of time. This position is a result of one or more [deals](#). Do not confuse positions with valid [pending orders](#), which are also displayed on the Trading tab of the Toolbox window.

If individual positions are allowed ([ACCOUNT_MARGIN_MODE_RETAIL_HEDGING](#)), multiple positions can be open for one symbol. In this case, PositionClose will close a position with the lowest ticket.

PositionClosePartial

Partially closes a position on a specified symbol in case of a "hedging" accounting.

```
bool PositionClosePartial(
    const string  symbol,           // symbol
    const double  volume,           // volume
    ulong         deviation=ULONG_MAX // deviation
)
```

Partially closes a position having a specified ticket in case of a "hedging" accounting.

```
bool PositionClosePartial(
    const ulong   ticket,           // position ticket
    const double  volume,           // volume
    ulong         deviation=ULONG_MAX // deviation
)
```

Parameters

symbol

[in] Name of a trading instrument, on which a position is closed partially. If a symbol (not a ticket) is specified for a position partial closing, the first detected position having a specified MagicNumber ([Expert Advisor ID](#)) on the symbol is selected. Therefore, it is sometimes better to use PositionClosePartial() with a specified position ticket.

volume

[in] Volume, by which a position should be decreased. If the value exceeds the volume of a partially closed position, it is closed in full. No position in the opposite direction is opened.

ticket

[in] Closed position ticket.

deviation=ULONG_MAX

[in] The maximum deviation from the current price (in points).

Return Value

true if the basic check of structures is successful, otherwise false.

Note

A successful completion of the PositionClosePartial(...) method does not always mean a successful execution of a trading operation. You should call the [ResultRetcode\(\)](#) method to check the result of a trade request (trade server return code).

In the "netting" system ([ACCOUNT_MARGIN_MODE_RETAIL_NETTING](#) and [ACCOUNT_MARGIN_MODE_EXCHANGE](#)), for each [symbol](#), at any given moment of time, only one [position](#) can be open, which is the result of one or more [deals](#). Do not confuse the current [pending orders](#) with positions that are also displayed on the "Trade" tab of the client terminal's "Toolbox" panel.

In case of the position representation ([ACCOUNT_MARGIN_MODE_RETAIL_HEDGING](#)), multiple positions can be opened on each symbol simultaneously. In this case, PositionClose closes a position having a least ticket.

PositionCloseBy

Closes a position with the specified ticket by an opposite position.

```
bool PositionCloseBy(  
    const ulong   ticket,           // position ticket  
    const ulong   ticket_by        // opposite position ticket  
)
```

Parameters

ticket

[in] Ticket of the closed position.

ticket_by

[in] Ticket of the opposite position used for closing.

Returned value

true - the basic check of structures is successful, otherwise - false.

Note

A successful completion of the `PositionCloseBy(...)` method does not always mean a successful execution of a trading operation. You should call the [ResultRetcode\(\)](#) method to check the result of a trade request (trade server return code).

Buy

Opens a long position with specified parameters.

```
bool Buy(  
    double      volume,           // position volume  
    const string symbol=NULL,     // symbol  
    double      price=0.0,        // execution price  
    double      sl=0.0,           // stop loss price  
    double      tp=0.0,           // take profit price  
    const string comment=""      // comment  
)
```

Parameters

volume

[in] Requested position volume.

symbol=NULL

[in] Position symbol. If it is not specified, the current symbol will be used.

price=0.0

[in] Price. If the price is not specified, the current market Ask price will be used.

sl=0.0

[in] Stop Loss price.

tp=0.0

[in] Take Profit price.

comment=""

[in] Comment.

Return Value

true - successful check of the structures, otherwise - false.

Note

Successful completion of the Buy(...) method does not always mean successful execution of the trade operation. It is necessary to check the result of trade request (trade server [return code](#)) using [ResultRetcode\(\)](#) and value returned by [ResultDeal\(\)](#).

Sell

Opens a short position with specified parameters.

```
bool Sell(  
    double      volume,           // position volume  
    const string symbol=NULL,     // symbol  
    double      price=0.0,        // execution price  
    double      sl=0.0,           // stop loss price  
    double      tp=0.0,           // take profit price  
    const string comment=""      // comment  
)
```

Parameters

volume

[in] Requested position volume.

symbol=NULL

[in] Position symbol. If the symbol is not specified, the current symbol will be used.

price=0.0

[in] Price. If the price is not specified, the current market Bid price will be used.

sl=0.0

[in] Stop Loss price.

tp=0.0

[in] Take Profit price.

comment=""

[in] Comment.

Return Value

true - successful check of the structures, otherwise - false.

Note

Successful completion of the Sell(...) method does not always mean successful execution of the trade operation. It is necessary to check the result of trade request (trade server [return code](#)) using [ResultRetcode\(\)](#) and value returned by [ResultDeal\(\)](#).

BuyLimit

Places the pending order of Buy Limit type (buy at the price lower than current market price) with specified parameters.

```
bool BuyLimit(
    double          volume,           // order volume
    double          price,           // order price
    const string    symbol=NULL,     // symbol
    double          sl=0.0,          // stop loss price
    double          tp=0.0,          // take profit price
    ENUM_ORDER_TYPE_TIME type_time=ORDER_TIME_GTC, // order lifetime
    datetime        expiration=0,    // order expiration time
    const string    comment=""       // comment
)
```

Parameters

volume

[in] Requested order volume.

price

[in] Order price.

symbol=NULL

[in] Order symbol. If the symbol is not specified, the current symbol will be used.

sl=0.0

[in] Stop Loss price.

tp=0.0

[in] Take Profit price.

type_time=ORDER_TIME_GTC

[in] Order lifetime from [ENUM_ORDER_TYPE_TIME](#) enumeration.

expiration=0

[in] Order expiration time (used only if type_time=[ORDER_TIME_SPECIFIED](#)).

comment=""

[in] Order comment.

Return Value

true - successful check of the structures, otherwise - false.

Note

Successful completion of the BuyLimit(...) method does not always mean successful execution of the trade operation. It is necessary to check the result of trade request (trade server [return code](#)) using [ResultRetcode\(\)](#) and value returned by [ResultOrder\(\)](#).

BuyStop

Places the pending order of Buy Stop type (buy at the price higher than current market price) with specified parameters.

```
bool BuyStop(
    double          volume,           // order volume
    double          price,           // order price
    const string    symbol=NULL,      // symbol
    double          sl=0.0,           // stop loss price
    double          tp=0.0,           // take profit price
    ENUM_ORDER_TYPE_TIME type_time=ORDER_TIME_GTC, // order lifetime
    datetime        expiration=0,     // order expiration time
    const string    comment=""        // comment
)
```

Parameters

volume

[in] Requested order volume.

price

[in] Order price.

symbol=NULL

[in] Order symbol. If the symbol isn't specified, the current symbol will be used.

sl=0.0

[in] Stop Loss price.

tp=0.0

[in] Take Profit price.

type_time=ORDER_TIME_GTC

[in] Order lifetime from [ENUM_ORDER_TYPE_TIME](#) enumeration.

expiration=0

[in] Order expiration time (used only if type_time=[ORDER_TIME_SPECIFIED](#)).

comment=""

[in] Order comment.

Return Value

true - successful check of the structures, otherwise - false.

Note

Successful completion of the BuyStop(...) method does not always mean successful execution of the trade operation. It is necessary to check the result of trade request (trade server [return code](#)) using [ResultRetcode\(\)](#) and value returned by [ResultOrder\(\)](#).

SellLimit

Places the pending order of Sell Limit type (sell at the price higher than current market price) with specified parameters.

```
bool SellLimit(
    double          volume,           // order volume
    double          price,           // order price
    const string    symbol=NULL,     // symbol
    double          sl=0.0,          // stop loss price
    double          tp=0.0,          // take profit price
    ENUM_ORDER_TYPE_TIME type_time=ORDER_TIME_GTC, // order lifetime
    datetime        expiration=0,    // order expiration time
    const string    comment=""       // comment
)
```

Parameters

volume

[in] Requested order volume.

price

[in] Order price.

symbol=NULL

[in] Order symbol. If the symbol is not specified, the current symbol will be used.

sl=0.0

[in] Stop Loss price.

tp=0.0

[in] Take Profit price.

type_time=ORDER_TIME_GTC

[in] Order lifetime from [ENUM_ORDER_TYPE_TIME](#) enumeration.

expiration=0

[in] Order expiration time (used only if type_time=[ORDER_TIME_SPECIFIED](#)).

comment=""

[in] Order comment.

Return Value

true - successful check of the structures, otherwise - false.

Note

Successful completion of the SellLimit(...) method does not always mean successful execution of the trade operation. It is necessary to check the result of trade request (trade server [return code](#)) using [ResultRetcode\(\)](#) and value returned by [ResultOrder\(\)](#).

SellStop

Places the pending order of Sell Stop type (sell at the price lower than current market price) with specified parameters.

```
bool SellStop(
    double          volume,           // order volume
    double          price,           // order price
    const string    symbol=NULL,     // symbol
    double          sl=0.0,          // stop loss price
    double          tp=0.0,          // take profit price
    ENUM_ORDER_TYPE_TIME type_time=ORDER_TIME_GTC, // order lifetime
    datetime        expiration=0,    // order expiration time
    const string    comment=""       // comment
)
```

Parameters

volume

[in] Requested order volume.

price

[in] Order price.

symbol=NULL

[in] Order symbol. If the symbol is not specified, the current symbol will be used.

sl=0.0

[in] Stop Loss price.

tp=0.0

[in] Take Profit price.

type_time=ORDER_TIME_GTC

[in] Order lifetime from [ENUM_ORDER_TYPE_TIME](#) enumeration.

expiration=0

[in] Order expiration time (used only if type_time=[ORDER_TIME_SPECIFIED](#)).

comment=""

[in] Order comment.

Return Value

true - successful check of the structures, otherwise - false.

Note

Successful completion of the SellStop(...) method does not always mean successful execution of the trade operation. It is necessary to check the result of trade request (trade server [return code](#)) using [ResultRetcode\(\)](#) and value returned by [ResultOrder\(\)](#).

Request

Gets the copy of the last request structure.

```
void Request (
    MqlTradeRequest& request // reference
) const
```

Parameters

request

[out] Reference to the copied structure.

Return Value

None.

RequestAction

Gets the trade operation type.

```
ENUM_TRADE_REQUEST_ACTIONS RequestAction() const
```

Return Value

Trade operation type used in the last request from [ENUM_TRADE_REQUEST_ACTIONS](#) enumeration.

RequestActionDescription

Gets the trade operation type as string.

```
string RequestActionDescription() const
```

Return Value

Trade operation type (as string) used in the last request.

RequestMagic

Gets the magic number of the Expert Advisor.

```
ulong RequestMagic() const
```

Return Value

The magic number (ID) of the Expert Advisor, used in the last request.

RequestOrder

Gets the order ticket.

```
ulong RequestOrder() const
```

Return Value

Order ticket of the last request.

RequestSymbol

Gets the name of the symbol.

```
string RequestSymbol() const
```

Return Value

The name of the symbol used in the last request.

RequestVolume

Gets the trade volume (in lots).

```
double RequestVolume() const
```

Return Value

The requested trade volume (in lots) used in the last request.

RequestPrice

Gets the order execution price.

```
double RequestPrice() const
```

Return Value

Order execution price used in the last request.

RequestStopLimit

Gets the price of pending order of Stop Limit type.

```
double RequestStoplimit() const
```

Return Value

The price of pending order of Stop Limit type used in the last request.

RequestSL

Gets the Stop Loss price of an order.

```
double RequestSL() const
```

Return Value

The Stop Loss price used in the last request.

RequestTP

Gets the Take Profit price of the order.

```
double RequestTP() const
```

Return Value

The Take Profit price used in the last request.

RequestDeviation

Gets the maximum price deviation from a requested price.

```
ulong RequestDeviation() const
```

Return Value

The maximum allowable price deviation from a requested price used in the last request.

RequestType

Gets the type of the order.

```
ENUM_ORDER_TYPE RequestType() const
```

Return Value

Order type used in the last request from [ENUM_ORDER_TYPE](#) enumeration.

RequestTypeDescription

Gets the type of the order (as string).

```
string RequestTypeDescription() const
```

Return Value

The order type (as string) used in the last request.

RequestTypeFilling

Gets the filling type of the order.

```
ENUM_ORDER_TYPE_FILLING RequestTypeFilling() const
```

Return Value

The filling type of the order from [ENUM_ORDER_TYPE_FILLING](#) used in the last request.

RequestTypeFillingDescription

Gets the filling type of the order (as string).

```
string RequestTypeFillingDescription() const
```

Return Value

The filling type (as string) of the order used in the last request.

RequestTypeTime

Gets the validity period of the order.

```
ENUM_ORDER_TYPE_TIME RequestTypeTime() const
```

Return Value

The validity period of the order from [ENUM_ORDER_TYPE_TIME](#) enumeration used in the last request.

RequestTypeTimeDescription

Gets the validity period of the order (as string).

```
string RequestTypeTimeDescription() const
```

Return Value

The validity period of the order (as string) used in the last request.

RequestExpiration

Gets the expiration time of a pending order.

```
datetime RequestExpiration() const
```

Return Value

The expiration time of a pending order used in the last request.

RequestComment

Gets the comment of the order.

```
string RequestComment() const
```

Return Value

The comment of the order used in the last request.

RequestPosition

Gets position ticket.

```
ulong RequestPosition() const
```

Return value

Position ticket used in the last request.

RequestPositionBy

Gets opposite position ticket.

```
ulong RequestPositionBy() const
```

Return value

Opposite position ticket used in the last request.

Result

Gets the copy of the structure of the last request result.

```
void Result(  
    MqlTradeResult& result    // reference  
    ) const
```

Parameters

result

[out] Reference to the structure of [MqlTradeResult](#) type for copying.

Return Value

None.

ResultRetcode

Gets the code of request execution result.

```
uint ResultRetcode() const
```

Return Value

The [code](#) of request result.

ResultRetcodeDescription

Gets the code of request execution result as a string.

```
string ResultRetcodeDescription() const
```

Return Value

[Code of the last request](#) result as a string.

ResultDeal

Gets the deal ticket.

```
ulong ResultDeal() const
```

Return Value

Deal ticket if the deal is executed.

ResultOrder

Gets the order ticket.

```
ulong ResultOrder() const
```

Return Value

Order ticket if the order is placed.

ResultVolume

Gets the volume of deal or order.

```
double ResultVolume() const
```

Return Value

Volume of deal or order confirmed by a broker.

ResultPrice

Gets the price confirmed by a broker.

```
double ResultPrice() const
```

Return Value

Price confirmed by a broker.

ResultBid

Gets the current bid price (the requote).

```
double ResultBid() const
```

Return Value

Current bid price (the requote).

ResultAsk

Gets the current ask price (the requote).

```
double ResultAsk() const
```

Return Value

Current ask price (the requote).

ResultComment

Gets the broker comment.

```
string ResultComment() const
```

Return Value

Broker comment to the operation.

CheckResult

Gets the copy of the structure of the last request check result.

```
void CheckResult(  
    MqlTradeCheckResult& check_result    // reference  
    ) const
```

Parameters

check_result

[out] Reference to the target structure of the [MqlTradeCheckResult](#) type for copying.

Return Value

None.

CheckResultRetcode

Gets the value of the retcode field of [MqlTradeCheckResult](#) type, filled while checking the request correctness.

```
uint CheckResultRetcode() const
```

Return Value

The value of the retcode field (error code) of [MqlTradeCheckResult](#) type filled while checking the request correctness.

CheckResultRetcodeDescription

Gets the string description of the retcode field of [MqlTradeCheckResult](#) type filled while checking the request correctness.

```
string ResultRetcodeDescription() const
```

Return Value

The string description of the retcode field (Error code) of [MqlTradeCheckResult](#) type filled while checking the request correctness.

CheckResultBalance

Gets the value of the balance field of [MqlTradeCheckResult](#) type filled while checking the request correctness.

```
double CheckResultBalance() const
```

Return Value

The value of the balance field (balance value that will be after the execution of the trade operation) of [MqlTradeCheckResult](#) type filled while checking the request correctness.

CheckResultEquity

Gets the value of the equity field of [MqlTradeCheckResult](#) type filled while checking the request correctness.

```
double CheckResultEquity() const
```

Return Value

The value of the equity field (equity value that will be after the execution of the trade operation) of [MqlTradeCheckResult](#) type filled while checking the request correctness.

CheckResultProfit

Gets the value of a floating profit.

```
double CheckResultProfit() const
```

Return Value

The value of a floating profit after executing a trading operation.

CheckResultMargin

Gets the value of the margin field of [MqlTradeCheckResult](#) type filled while checking the request correctness.

```
double CheckResultMargin() const
```

Return Value

The value of the margin field (margin required for the trade operation) of [MqlTradeCheckResult](#) type filled while checking the request correctness.

CheckResultMarginFree

Gets the value of the margin_free field of [MqlTradeCheckResult](#) type filled while checking the request correctness.

```
double CheckResultMarginFree() const
```

Return Value

The value of the margin_free field (free margin that will be left after the execution of the trade operation) of [MqlTradeCheckResult](#) type filled while checking the request correctness.

CheckResultMarginLevel

Gets the value of the margin_level field of [MqlTradeCheckResult](#) type filled while checking the request correctness.

```
double CheckResultMarginLevel() const
```

Return Value

The value of the margin_level field (margin level that will be set after the execution of the trade operation) of [MqlTradeCheckResult](#) type filled while checking the request correctness.

CheckResultComment

The value of the comment field of [MqlTradeCheckResult](#) type filled while checking the request correctness.

```
string CheckResultComment() const
```

Return Value

The value of the comment field (comment to the reply code, error description) of [MqlTradeCheckResult](#) type filled while checking the request correctness.

PrintRequest

Prints the last request parameters into journal.

```
void PrintRequest() const
```

Return Value

None.

PrintResult

Prints the results of the last request into journal.

```
void PrintResult() const
```

Return Value

None.

FormatRequest

Prepares the formatted string with last request parameters.

```
string FormatRequest(  
    string&          str,          // string  
    const MqlTradeRequest& request // request  
) const
```

Parameters

str

[in] Target string passed by reference.

request

[in] A structure of [MqlTradeRequest](#) type with parameters of the last request.

Return Value

None.

FormatRequestResult

Prepares the formatted string with results of the last request execution.

```
string FormatRequestResult(  
    string&          str,          // string  
    const MqlTradeRequest& request, // request  
    const MqlTradeResult& result   // result  
) const
```

Parameters

str

[in] Target string passed by reference.

request

[in] A structure of [MqlTradeRequest](#) type with parameters of the last request.

result

[in] A structure of [MqlTradeResult](#) type with results of the last request.

Return Value

None.

CTerminalInfo

CTerminalInfo is a class for simplified access to the properties of mql5 program environment.

Description

CTerminalInfo class provides access to the properties of mql5 program environment.

Declaration

```
class CTerminalInfo : public CObject
```

Title

```
#include <Trade\TerminalInfo.mqh>
```

Inheritance hierarchy

CObject

CTerminalInfo

Class methods by groups

Methods for access to the properties of integer type	
<u>Build</u>	Gets the build number of the client terminal
<u>IsConnected</u>	Gets the information about connection to trade server
<u>IsDLLsAllowed</u>	Gets the information about permission of DLL usage
<u>IsTradeAllowed</u>	Gets the information about permission to trade
<u>IsEmailEnabled</u>	Gets the information about permission to send e-mails to SMTP server and login, specified in the terminal settings
<u>IsFtpEnabled</u>	Gets the information about permission to send trade reports to FTP server and login, specified in the terminal settings
<u>MaxBars</u>	Gets the information about maximum number of bars on chart
<u>CodePage</u>	Gets the information about the code page of the language in the client terminal
<u>CPUcores</u>	Gets the information about the CPU cores
<u>MemoryPhysical</u>	Gets the information about the physical memory (in Mb)

<u>MemoryTotal</u>	Gets the information about the total memory available for the terminal/agent process (in Mb)
<u>MemoryAvailable</u>	Gets the information about the free memory available for the terminal/agent process (in Mb)
<u>MemoryUsed</u>	Gets the information about the memory used by the terminal/agent process (in Mb)
<u>IsX64</u>	Gets the information about the type of the client terminal
<u>OpenCLSupport</u>	Gets the information about the version of OpenCL supported by video card
<u>DiskSpace</u>	Gets the information about free disk space (in Mb)
Methods for access to the properties of string type	
<u>Language</u>	Gets the language of the client terminal
<u>Name</u>	Gets the name of the client terminal
<u>Company</u>	Gets the company name of the client terminal
<u>Path</u>	Gets the folder of the client terminal
<u>DataPath</u>	Gets the data folder of the client terminal
<u>CommonDataPath</u>	Gets the common data folder of all client terminals, installed on the computer
Access to MQL5 API functions	
<u>InfoInteger</u>	Gets the value of the property of integer type
<u>InfoString</u>	Gets the value of property of string type

Methods inherited from class CObject

Prev, [Prev](#), [Next](#), [Next](#), [Save](#), [Load](#), [Type](#), [Compare](#)

Build

Gets the build number of the client terminal.

```
int CBuild() const
```

Return Value

Build number of the client terminal.

Note

The terminal build number is defined by [TerminalInfoInteger\(\)](#) function ([TERMINAL_BUILD](#) property).

IsConnected

Gets the information about connection to trade server.

```
bool IsConnected() const
```

Return Value

true - the terminal is connected to a trade server, otherwise - false.

Note

Connection status is defined by [TerminalInfoInteger\(\)](#) function ([TERMINAL_CONNECTED](#) property).

IsDLLsAllowed

Gets the information about permission of DLL usage.

```
bool IsDLLsAllowed() const
```

Return Value

true - DLL usage is allowed, otherwise - false.

Note

Permission of DLL usage is defined by [TerminalInfoInteger\(\)](#) function ([TERMINAL_DLLS_ALLOWED](#) property).

IsTradeAllowed

Gets the information about permission to trade.

```
bool IsTradeAllowed() const
```

Return Value

true - trade allowed, otherwise - false.

Note

Permission to trade is defined by [TerminalInfoInteger\(\)](#) function ([TERMINAL_TRADE_ALLOWED](#) property).

IsEmailEnabled

Gets the information about permission to send e-mails to SMTP server and login specified in the terminal settings.

```
bool IsEmailEnabled() const
```

Return Value

true - sending e-mails is allowed, otherwise - false.

Note

Permission to send e-mails is defined by [TerminalInfoInteger\(\)](#) function ([TERMINAL_EMAIL_ENABLED](#) property).

IsFtpEnabled

Gets the information about permission to send trade reports to FTP server and login specified in the terminal settings.

```
bool IsFtpEnabled() const
```

Return Value

true - sending trade reports to FTP server is allowed, otherwise - false.

Note

Permission to send trade reports is defined [TerminalInfoInteger\(\)](#) function ([TERMINAL_FTP_ENABLED](#) property).

MaxBars

Gets the maximum number of bars on chart specified in the terminal settings.

```
int MaxBars() const
```

Return Value

Maximum number of bars on the chart.

Note

The maximum number of bars on chart is defined by [TerminalInfoInteger\(\)](#) function ([TERMINAL_MAXBARS](#) property).

CodePage

Gets the information about code page of the language in the terminal.

```
int CodePage () const
```

Return Value

Code page of the language in the client terminal.

Note

Code page of the language is defined by [TerminalInfoInteger\(\)](#) function ([TERMINAL_CODEPAGE](#) property).

CPUCores

Gets the information about the number of CPU cores in the system.

```
int CPUCores () const
```

Return Value

Number of CPU cores in the system.

Note

The number of CPU cores is defined by [TerminalInfoInteger\(\)](#) function ([TERMINAL_CPU_CORES](#) property).

MemoryPhysical

Gets the information about the physical memory (in Mb).

```
int MemoryPhysical() const
```

Return Value

Physical memory (in Mb).

Note

The physical memory is defined by [TerminalInfoInteger\(\)](#) function ([TERMINAL_MEMORY_PHYSICAL](#) property).

MemoryTotal

Gets the information about the total memory available to the terminal/agent (in Mb).

```
int MemoryTotal() const
```

Return Value

Total memory (in Mb) available to the terminal/agent.

Note

The total memory available to the terminal/agent is defined by [TerminalInfoInteger\(\)](#) function ([TERMINAL_MEMORY_TOTAL](#) property).

MemoryAvailable

Gets the information about the free memory available to the client terminal/agent (in Mb).

```
int MemoryTotal() const
```

Return Value

Free memory (in Mb) available to the terminal/agent.

Note

The free memory available to the client terminal/agent is defined by [TerminalInfoInteger\(\)](#) function ([TERMINAL_MEMORY_TOTAL](#) property).

MemoryUsed

Gets the information about the memory used by the client terminal/agent (in Mb).

```
int MemoryUsed() const
```

Return Value

The memory used by the client terminal/agent (in Mb).

Note

The memory used by the client terminal/agent is defined by [TerminalInfoInteger\(\)](#) function ([TERMINAL_MEMORY_USED](#) property).

IsX64

Gets the information about the type of the client terminal.

```
bool IsX64() const
```

Return Value

true - 64-bit version is used, otherwise - false.

Note

The type of the terminal is defined by [TerminalInfoInteger\(\)](#) function ([TERMINAL_X64](#) property).

OpenCLSupport

Gets the information about the version of OpenCL supported by video card.

```
int OpenCLSupport() const
```

Return Value

OpenCL version having the following form: 0x00010002 = "1.2". 0 means that OpenCL is not supported.

Note

OpenCL version is defined by [TerminalInfoInteger\(\)](#) function ([TERMINAL_OPENCL_SUPPORT](#) property).

DiskSpace

Gets the information about free disk space available for MQL5\Files folder of the terminal/agent (in Mb).

```
int MDiskSpace() const
```

Return Value

Free disk space.

Note

Free disk space is defined by [TerminalInfoInteger\(\)](#) function ([TERMINAL_DISK_SPACE](#) property).

Language

Gets the information about the language of the client terminal.

```
string Language() const
```

Return Value

Language used in the client terminal.

Note

The terminal language is defined by [TerminalInfoString\(\)](#) function ([TERMINAL_LANGUAGE](#) property).

Name

Gets the information on the name of the client terminal.

```
string Name() const
```

Return Value

Name of the client terminal.

Note

The name of the terminal is defined by [TerminalInfoString\(\)](#) function ([TERMINAL_NAME](#) property).

Company

Gets the information about the name of the company.

```
string Company() const
```

Return Value

The name of the company.

Note

The company name is defined by [TerminalInfoString\(\)](#) function ([TERMINAL_COMPANY](#) property).

Path

Gets the client terminal folder.

```
string Path() const
```

Return Value

The client terminal folder.

Note

The client terminal folder is used by [TerminalInfoString\(\)](#) function ([TERMINAL_PATH](#) property).

DataPath

Gets the information about the terminal data folder.

```
string DataPath() const
```

Return Value

Data folder of the client terminal.

Note

Client terminal data folder is defined by [TerminalInfoString\(\)](#) function ([TERMINAL_DATA_PATH](#) property).

CommonDataPath

Gets the common data folder of all client terminals installed on the computer.

```
string CommonDataPath() const
```

Return Value

Common data folder of all installed terminals.

Note

The common data folder of all installed terminals is defined by [TerminalInfoString\(\)](#) function ([COMMON_DATA_PATH](#) property).

InfoInteger

Returns the value of a corresponding integer property of the mql5 program environment.

```
int TerminalInfoInteger(  
    int property_id    // identifier of a property  
);
```

Parameters

property_id

[in] Identifier of a property. It can be one of the values of the enumeration [ENUM_TERMINAL_INFO_INTEGER](#).

Return Value

Value of int type.

Note

The property value is defined by [TerminalInfoInteger\(\)](#) function.

InfoString

The function returns the value of a corresponding property of the mql5 program environment. The property must be of string type.

```
string TerminalInfoString(  
    int property_id    // property ID  
);
```

Parameters

property_id

[in] Identifier of a property. It can be one the values of the enumeration [ENUM_TERMINAL_INFO_STRING](#).

Return Value

Value of string type.

Note

The property value is defined by [TerminalInfoString\(\)](#) function.

Classes for Creating and Testing Trading Strategies

This section contains technical details of working with classes for creation and testing of trading strategies and description of the relevant components of the MQL5 standard library.

The use of these classes will save time when creating (and especially testing) trading strategies.

MQL5 Standard Library (in terms of trading strategies) is placed in the terminal directory, in the Include\Expert folder.

Base classes	Description
<u>CExpertBase</u>	Base class for all trading strategy classes
<u>CExpert</u>	Base class for Expert Advisor
<u>CExpertSignal</u>	Base class for Trading Signal classes
<u>CExpertTrailing</u>	Base class for Trailing Stop classes
<u>CExpertMoney</u>	Base class for Money Management classes

Trading signal classes	Description
<u>CSignalAC</u>	The module of signals based on market models of the indicator Accelerator Oscillator.
<u>CSignalAMA</u>	The module of signals based on market models of the indicator Adaptive Moving Average.
<u>CSignalAO</u>	The module of signals based on market models of the indicator Awesome Oscillator.
<u>CSignalBearsPower</u>	The module of signals based on market models of the oscillator Bears Power.
<u>CSignalBullsPower</u>	The module of signals based on market models of the oscillator Bulls Power.
<u>CSignalCCI</u>	The module of signals based on market models of the oscillator Commodity Channel Index.
<u>CSignalDeM</u>	The module of signals based on market models of the oscillator DeMarker.
<u>CSignalDEMA</u>	The module of signals based on market models of the indicator Double Exponential Moving Average.
<u>CSignalEnvelopes</u>	The module of signals based on market models of the indicator Envelopes.
<u>CSignalFrAMA</u>	The module of signals based on market models of the indicator Fractal Adaptive Moving Average.

Trading signal classes	Description
<u>CSignalITF</u>	The module of filtration of signals by time.
<u>CSignalMACD</u>	The module of signals based on market models of the oscillator MACD.
<u>CSignalMA</u>	The module of signals based on market models of the indicator Moving Average.
<u>CSignalSAR</u>	The module of signals based on market models of the indicator Parabolic SAR.
<u>CSignalRSI</u>	The module of signals based on market models of the oscillator Relative Strength Index.
<u>CSignalRVI</u>	The module of signals based on market models of the oscillator Relative Vigor Index.
<u>CSignalStoch</u>	The module of signals based on market models of the oscillator Stochastic.
<u>CSignalTRIX</u>	The module of signals based on market models of the oscillator Triple Exponential Average.
<u>CSignalTEMA</u>	The module of signals based on market models of the indicator Triple Exponential Moving Average.
<u>CSignalWPR</u>	The module of signals based on market models of the oscillator Williams Percent Range.

Trailing Stop classes	Description
<u>CTrailingFixedPips</u>	This class implements Trailing Stop algorithm based on fixed points
<u>CTrailingMA</u>	This class implements Trailing Stop algorithm based on the values of Moving Average indicator
<u>CTrailingNone</u>	A stub class, it does not use any Trailing Stop algorithm
<u>CTrailingPSAR</u>	This class implements Trailing Stop algorithm based on the values of Parabolic SAR indicator

Money Management classes	Description
<u>CMoneyFixedLot</u>	A class with an algorithm based on trading with predefined fixed lot size.
<u>CMoneyFixedMargin</u>	A class with an algorithm based on trading with predefined fixed margin.

<u>CMoneyFixedRisk</u>	A class with an algorithm based on trading with predefined risk.
<u>CMoneyNone</u>	A class with an algorithm based on trading with minimal allowed lot size.
<u>CMoneySizeOptimized</u>	A class with an algorithm based on trading with variable lot size, depending on the results of the previous deals.

Base classes for Expert Advisors

This section contains technical details of working with classes for creation and testing of trading strategies and description of the relevant components of the MQL5 standard library.

The use of these classes will save time when creating (and especially testing) trading strategies.

MQL5 Standard Library (in terms of trading strategies classes) is placed in the terminal directory, in the Include\Expert folder.

Class	Description
<u>CExpertBase</u>	Base class for all trading strategy classes
<u>CExpert</u>	Base class for Expert Advisor
<u>CExpertSignal</u>	Base class for Trading Signal classes
<u>CExpertTrailing</u>	Base class for Trailing Stop classes
<u>CExpertMoney</u>	Base class for Money Management classes

CExpertBase

CExpertBase is a base class for the [CExpert](#) class and all auxiliary trading strategy classes.

Description

CExpertBase provides the data and methods, which are common to all objects of the Expert Advisor.

Declaration

```
class CExpertBase : public CObject
```

Title

```
#include <Expert\ExpertBase.mqh>
```

Inheritance hierarchy

[CObject](#)

CExpertBase

Direct descendants

[CExpert](#), [CExpertMoney](#), [CExpertSignal](#), [CExpertTrailing](#)

Class Methods by Groups

Public Methods:

Initialization	
virtual Init	Initializes the object
virtual ValidationSettings	Checks the settings
Parameters	
Symbol	Sets the symbol
Period	Sets the timeframe
Magic	Sets the Expert Advisor ID
Indicators and Timeseries	
virtual SetPriceSeries	Sets pointers to external timeseries (price series)
virtual SetOtherSeries	Sets pointers to external timeseries (non-price series)
virtual InitIndicators	Initializes the indicators and timeseries
Access to Protected Data	
InitPhase	Gets the current phase of object initialization

<u>TrendType</u>	Sets trend type
<u>UsedSeries</u>	Gets bitmask of timeseries used
<u>EveryTick</u>	Sets the "Every tick" flag
Access to Timeseries	
<u>Open</u>	Gets the element of the Open timeseries by index
<u>High</u>	Gets the element of the High timeseries by index
<u>Low</u>	Gets the element of the Low timeseries by index
<u>Close</u>	Gets the element of the Close timeseries by index
<u>Spread</u>	Gets the element of the Spread timeseries by index
<u>Time</u>	Gets the element of the Time timeseries by index
<u>TickVolume</u>	Gets the element of the TickVolume timeseries by index
<u>RealVolume</u>	Gets the element of the RealVolume timeseries by index

Protected Methods:

Initialization of Timeseries	
<u>InitOpen</u>	Open timeseries initialization method
<u>InitHigh</u>	High timeseries initialization method
<u>InitLow</u>	Low timeseries initialization method
<u>InitClose</u>	Close timeseries initialization method
<u>InitSpread</u>	Spread timeseries initialization method
<u>InitTime</u>	Time timeseries initialization method
<u>InitTickVolume</u>	TickVolume timeseries initialization method
<u>InitRealVolume</u>	RealVolume timeseries initialization method
Service Methods	
virtual <u>PriceLevelUnit</u>	Gets the price level unit
virtual <u>StartIndex</u>	Gets the index of starting bar to analyze

virtual CompareMagic	Compares the Expert Advisor ID with the specified value
--------------------------------------	---

Methods inherited from class CObjectPrev, Prev, Next, Next, [Save](#), [Load](#), [Type](#), [Compare](#)

InitPhase

Gets the current phase of the object initialization.

```
ENUM_INIT_PHASE InitPhase()
```

Return Value

Current phase of the object initialization.

Note

The object initialization consist of several phases:

1. Start initialization.

- start - after finish of the constructor
- finish - after successful completion of the [Init\(...\)](#) method.
- allowed - call of the [Init\(...\)](#) method
- not allowed - call of the [ValidationSettings\(\)](#) method and other initialization methods

2. Parameters setting phase. In this phase you need to set all the object parameters, used for creation of indicators.

- start - after successful completion of the [Init\(...\)](#) method
- finish - after successful completion of the [ValidationSettings\(\)](#) method
- allowed - call of [Symbol\(...\)](#) and [Period\(...\)](#) methods
- not allowed - call of the [Init\(...\)](#), [SetPriceSeries\(...\)](#), [SetOtherSeries\(...\)](#) and [InitIndicators\(...\)](#) methods

3. Checking of parameters.

- start - after successful completion of the [ValidationSettings\(\)](#) method
- finish - after successful completion of the [InitIndicators\(...\)](#) method
- allowed - call of the [Symbol\(...\)](#), [Period\(...\)](#) and [InitIndicators\(...\)](#) methods
- not allowed - call of any other initialization methods

4. Finish of initialization.

- start - after successful completion of the [InitIndicators\(...\)](#) method
- not allowed - call of initialization methods

TrendType

Sets trend type.

```
void TrendType(  
    M_TYPE_TREND value // value  
)
```

Parameters

value

[in] New value of trend type.

Return Value

None.

UsedSeries

Gets the bitmask of timeseries used.

```
int UsedSeries()
```

Return Value

The list of used timeseries as bitmask.

Note

If the bit is set, the corresponding timeseries is used, if it is not set, the timeseries is not used.

The bit-timeseries correspondence:

- bit 0 - Open timeseries,
- bit 1 - High timeseries,
- bit 2 - Low timeseries,
- bit 3 - Close timeseries,
- bit 4 - Spread timeseries,
- bit 5 - Time timeseries,
- bit 6 - TickVolume timeseries,
- bit 7 - RealVolume timeseries.

EveryTick

Sets the "Every tick" flag.

```
void EveryTick(  
    bool    value        // flag  
)
```

Parameters

value

[in] New value of a flag.

Return Value

None.

Note

If the flag is set, each price (tick) change at a working symbol is processed.

If the flag is not set, the processing method is called only at a new bar on the working timeframe and symbol.

Open

Gets the element of the Open timeseries by index.

```
double Open(  
    int ind // index  
)
```

Parameters

ind

[in] Element index.

Return Value

If successful, it returns the numerical value of the Open timeseries element with specified index, otherwise it returns EMPTY_VALUE.

Note

The EMPTY_VALUE is returned in two cases:

1. Timeseries is not used (the corresponding bit is not set).
2. Element index is out of range.

High

Gets the element of the High timeseries by index.

```
double High(  
    int ind // index  
)
```

Parameters

ind

[in] Element index.

Return Value

If successful, it returns the numerical value of the High timeseries element with specified index, otherwise it returns EMPTY_VALUE.

Note

The EMPTY_VALUE is returned in two cases:

1. Timeseries is not used (the corresponding bit is not set).
2. Element index is out of range.

Low

Gets the element of the Low timeseries by index.

```
double Low(  
    int ind // index  
)
```

Parameters

ind

[in] Element index.

Return Value

If successful, it returns the numerical value of the Low timeseries element with specified index, otherwise it returns EMPTY_VALUE.

Note

The EMPTY_VALUE is returned in two cases:

1. Timeseries is not used (the corresponding bit is not set).
2. Element index is out of range.

Close

Gets the element of the Close timeseries by index.

```
double Close (  
    int ind      // index  
)
```

Parameters

ind

[in] Element index.

Return Value

If successful, it returns the numerical value of the Close timeseries element with specified index, otherwise it returns EMPTY_VALUE.

Note

The EMPTY_VALUE is returned in two cases:

1. Timeseries is not used (the corresponding bit is not set).
2. Element index is out of range.

Spread

Gets the element of the Spread timeseries by index.

```
double Spread(  
    int ind // index  
)
```

Parameters

ind

[in] Element index.

Return Value

If successful, it returns the numerical value of the Spread timeseries element with specified index, otherwise it returns EMPTY_VALUE.

Note

The EMPTY_VALUE is returned in two cases:

1. Timeseries is not used (the corresponding bit is not set).
2. Element index is out of range.

Time

Gets the element of the Time timeseries by index.

```
datetime Time(  
    int ind      // index  
)
```

Parameters

ind

[in] Element index.

Return Value

If successful, it returns the numerical value of the Time timeseries element with specified index, otherwise it returns EMPTY_VALUE.

Note

The EMPTY_VALUE is returned in two cases:

1. Timeseries is not used (the corresponding bit is not set).
2. Element index is out of range.

TickVolume

Gets the element of the TickVolume timeseries by index.

```
long TickVolume(  
    int ind // index  
)
```

Parameters

ind

[in] Element index.

Return Value

If successful, it returns the numerical value of the TickVolume timeseries element with specified index, otherwise it returns EMPTY_VALUE.

Note

The EMPTY_VALUE is returned in two cases:

1. Timeseries is not used (the corresponding bit is not set).
2. Element index is out of range.

RealVolume

Gets the element of the RealVolume timeseries by index.

```
long RealVolume(  
    int ind // index  
)
```

Parameters

ind

[in] Element index.

Return Value

If successful, it returns the numerical value of the RealVolume timeseries element with specified index, otherwise it returns EMPTY_VALUE.

Note

The EMPTY_VALUE is returned in two cases:

1. Timeseries is not used (the corresponding bit is not set).
2. Element index is out of range.

Init

Initializes the object.

```
bool Init(  
    CSymbolInfo    symbol,    // symbol  
    ENUM_TIMEFRAMES period,    // timeframe  
    double         point      // point  
)
```

Parameters

symbol

[in] Pointer to the object of [CSymbolInfo](#) type for access to symbol information.

period

[in] Timeframe ([ENUM_TIMEFRAMES](#) enumeration).

point

[in] The "weight" of 2/4-digit point.

Return Value

true - successful completion, otherwise - false.

Symbol

Sets the object symbol.

```
bool Symbol(  
    string name // symbol  
)
```

Parameters

name

[in] Symbol.

Return Value

true - successful, otherwise - false.

Note

The setting of working symbol is necessary if the object uses the symbol different from symbol defined at the first initialization.

Period

Sets the object timeframe.

```
bool Period(  
    ENUM_TIMEFRAMES value    // timeframe  
)
```

Parameters

value

[in] Timeframe.

Return Value

true - successful, otherwise - false.

Note

The setting of working timeframe is necessary if the object uses the timeframe different from timeframe defined at the initialization.

Magic

Sets the Expert Advisor ID.

```
void Magic(  
    ulong value    // magic  
)
```

Parameters

value

[in] Expert Advisor ID.

Return Value

None.

ValidationSettings

Checks the settings.

```
virtual bool ValidationSettings()
```

Return Value

true - successful, otherwise - false.

SetPriceSeries

Sets pointers to external price series.

```
virtual bool SetPriceSeries(  
    CiOpen*   open,      // pointer  
    CiHigh*   high,      // pointer  
    CiLow*    low,       // pointer  
    CiClose*  close      // pointer  
)
```

Parameters

open

[in] Pointer to Open timeseries.

high

[in] Pointer to High timeseries.

low

[in] Pointer to Low timeseries.

close

[in] Pointer to Close timeseries.

Return Value

true - successful, otherwise - false.

Note

The setting of pointers to external timeseries (price series) is necessary if the object uses the symbol and timeframe (set during the first initialization) and price timeseries necessary for further work.

SetOtherSeries

Sets pointers to external non-price series.

```
virtual bool SetOtherSeries(  
    CiSpread*      spread,      // pointer  
    CiTime*        time,        // pointer  
    CiTickVolume*  tick_volume, // pointer  
    CiRealVolume*  real_volume  // pointer  
)
```

Parameters

spread

[in] Pointer to Spread timeseries.

time

[in] Pointer to Time timeseries.

tick_volume

[in] Pointer to TickVolume timeseries.

real_volume

[in] Pointer to RealVolume timeseries.

Return Value

true - successful, otherwise - false.

Note

The setting of pointers to external timeseries (price series) is necessary if the object uses the symbol and timeframe (set during the first initialization) and price timeseries necessary for further work.

InitIndicators

Initializes all indicators and time series.

```
virtual bool InitIndicators(  
    CIndicators* indicators=NULL    // pointer  
)
```

Parameters

indicators

[in] Pointer to collection of indicators and timeseries.

Return Value

true - successful, otherwise - false.

Note

The timeseries are initialized only if the object uses the symbol or timeframe different from the symbol or timeframe defined at initialization.

InitOpen

Initializes the Open timeseries.

```
bool InitOpen(  
    CIndicators* indicators // pointer  
)
```

Parameters

indicators

[in] Pointer to collection of indicators and timeseries.

Return Value

true - successful, otherwise - false.

Note

The Open timeseries is initialized only if the object uses the symbol/timeframe different from the symbol/timeframe defined at the first initialization (and timeseries is used further).

InitHigh

Initializes the High timeseries.

```
bool InitHigh(  
    CIndicators* indicators // pointer  
)
```

Parameters

indicators

[in] Pointer to collection of indicators and timeseries.

Return Value

true - successful, otherwise - false.

Note

The High timeseries is initialized only if the object uses the symbol/timeframe different from the symbol/timeframe defined at the first initialization (and timeseries is used further).

InitLow

Initializes the Low timeseries.

```
bool InitLow(  
    CIndicators* indicators // pointer  
)
```

Parameters

indicators

[in] Pointer to collection of indicators and timeseries.

Return Value

true - successful, otherwise - false.

Note

The Low timeseries is initialized only if the object uses the symbol/timeframe different from the symbol/timeframe defined at the first initialization (and timeseries is used further).

InitClose

Initializes the Close timeseries.

```
bool InitClose(  
    CIndicators* indicators // pointer  
)
```

Parameters

indicators

[in] Pointer to collection of indicators and timeseries.

Return Value

true - successful, otherwise - false.

Note

The Close timeseries is initialized only if Expert Advisor uses the symbol/timeframe different from the symbol/timeframe defined at the first initialization (and timeseries is used further).

InitSpread

Initializes the Spread timeseries.

```
bool InitSpread(  
    CIndicators* indicators // pointer  
)
```

Parameters

indicators

[in] Pointer to collection of indicators and timeseries.

Return Value

true - successful, otherwise - false.

Note

The Spread timeseries is initialized only if Expert Advisor uses the symbol/timeframe different from the symbol/timeframe defined at the first initialization (and timeseries is used further).

InitTime

Initializes the Time timeseries.

```
bool InitTime(  
    CIndicators* indicators // pointer  
)
```

Parameters

indicators

[in] Pointer to collection of indicators and timeseries.

Return Value

true - successful, otherwise - false.

Note

The Time timeseries is initialized only if Expert Advisor uses the symbol/timeframe different from the symbol/timeframe defined at the first initialization (and timeseries is used further).

InitTickVolume

Initializes the TickVolume timeseries.

```
bool InitTickVolume(  
    CIndicators* indicators // pointer  
)
```

Parameters

indicators

[in] Pointer to collection of indicators and timeseries.

Return Value

true - successful, otherwise - false.

Note

The TickVolume timeseries is initialized only if Expert Advisor uses the symbol/timeframe different from the symbol/timeframe defined at the first initialization (and timeseries is used further).

InitRealVolume

Initializes the RealVolume timeseries.

```
bool InitRealVolume(  
    CIndicators* indicators // pointer  
)
```

Parameters

indicators

[in] Pointer to collection of indicators and timeseries.

Return Value

true - successful, otherwise - false.

Note

The RealVolume timeseries is initialized only if Expert Advisor uses the symbol/timeframe different from the symbol/timeframe defined at the first initialization (and timeseries is used further).

PriceLevelUnit

Gets the price level unit.

```
virtual double PriceLevelUnit ()
```

Return Value

The value of price level unit.

Note

The method of a base class returns the "weight" of the 2/4 digits point.

StartIndex

Gets the index of starting bar to analyze.

```
virtual int StartIndex()
```

Return Value

The index of starting bar to analyze.

Note

The method returns 0 if the flag to analyze current bar is set to true (analysis from the current bar). If the flag is not set, it returns 1 (analysis from the last completed bar).

CompareMagic

Compares the Expert Advisor ID (magic) with the specified value.

```
virtual bool CompareMagic(  
    ulong magic    // identifier  
)
```

Parameters

magic

[in] Identifier value to compare.

Return Value

true - identifier matches the specified one, otherwise - false.

CExpert

CExpert is a base class for trading strategies.

It already has some elementary trading "skills". It has built-in algorithms for working with time series and indicators and a set of virtual methods for trading strategy.

How to use it:

1. Prepare an algorithm of the strategy;
2. Create your own class, inherited from CExpert class;
3. Override the virtual methods in your class with your own algorithms.

Description

The CExpert class is a set of virtual methods for implementation of trading strategies.

Note

A position is recognized as belonging to an Expert Advisor and managed by it based on the pair of properties `m_symbol` and `m_magic`. In the "hedging" mode, multiple positions can be opened for the same symbol, therefore the `m_magic` value is important.

Declaration

```
class CExpert : public CExpertBase
```

Title

```
#include <Expert\Expert.mqh>
```

Class Methods by Groups

Initialization	
<u>Init</u>	Class instance initialization method
virtual <u>InitSignal</u>	Initializes Trading Signal object
virtual <u>InitTrailing</u>	Initializes Trailing Stop object
virtual <u>InitMoney</u>	Initializes Money Management object
virtual <u>InitTrade</u>	Initializes Trade object
virtual <u>ValidationSettings</u>	Checks the settings
virtual <u>InitIndicators</u>	Initializes indicators and timeseries

virtual InitParameters	Expert Advisor parameters initialization method
virtual Deinit	Class instance deinitialization method
virtual DeinitSignal	Deinitializes Trading Signal object
virtual DeinitTrailing	Deinitializes Trailing Stop object
virtual DeinitMoney	Deinitializes Money Management object
virtual DeinitTrade	Deinitializes Trade object
virtual DeinitIndicators	Deinitializes indicators and timeseries
Parameters	
Magic	Sets the Expert Advisor ID
MaxOrders	Gets/sets the maximum amount of allowed orders
OnTickProcess	Sets a flag to proceed the "OnTick" event
OnTradeProcess	Sets a flag to proceed the "OnTrade" event
OnTimerProcess	Sets a flag to proceed the "OnTimer" event
OnChartEventProcess	Sets a flag to proceed the "OnChartEvent" event
OnBookEventProcess	Sets a flag to proceed the "OnBookEvent" event
Event Processing Methods	
OnTick	OnTick event handler
OnTrade	OnTrade event handler
OnTimer	OnTimer event handler
OnChartEvent	OnChartEvent event handler
OnBookEvent	OnBookEvent event handler
Update Methods	
Refresh	Updates all data
Processing	
Processing	Main processing algorithm
Market Entry Methods	
CheckOpen	Checks position opening conditions
CheckOpenLong	Checks conditions to open long position
CheckOpenShort	Checks conditions to open short position
OpenLong	Opens a long position
OpenShort	Opens a short position

Market Exit Methods	
<u>CheckClose</u>	Checks conditions to close current position
<u>CheckCloseLong</u>	Checks conditions to close long position
<u>CheckCloseShort</u>	Checks conditions to close short position
<u>CloseAll</u>	Closes the opened position and deletes all orders
<u>Close</u>	Closes the opened position
<u>CloseLong</u>	Closes the long position
<u>CloseShort</u>	Closes the short position
Position Reverse Methods	
<u>CheckReverse</u>	Checks conditions to reverse opened position
<u>CheckReverseLong</u>	Checks conditions to reverse long position
<u>CheckReverseShort</u>	Checks conditions to reverse short position
<u>ReverseLong</u>	Performs reverse operation of long position
<u>ReverseShort</u>	Performs reverse operation of short position
Position/Order Trailing Methods	
<u>CheckTrailingStop</u>	Checks conditions to modify position parameters
<u>CheckTrailingStopLong</u>	Checks Trailing Stop conditions of long position
<u>CheckTrailingStopShort</u>	Checks Trailing Stop conditions of short position
<u>TrailingStopLong</u>	Performs Trailing Stop for long position
<u>TrailingStopShort</u>	Performs Trailing Stop for short position
<u>CheckTrailingOrderLong</u>	Checks Trailing Stop conditions of Buy Limit/Stop order
<u>CheckTrailingOrderShort</u>	Checks Trailing Stop conditions of Sell Limit/Stop order
<u>TrailingOrderLong</u>	Performs Trailing Stop for Buy Limit/Stop order
<u>TrailingOrderShort</u>	Performs Trailing Stop for Sell Limit/Stop order
Order Delete Methods	
<u>CheckDeleteOrderLong</u>	Checks conditions to delete Buy order
<u>CheckDeleteOrderShort</u>	Checks conditions to delete Sell order
<u>DeleteOrders</u>	Deletes all orders

<u>DeleteOrder</u>	Deletes Stop/Limit order
<u>DeleteOrderLong</u>	Deletes Buy Limit/Stop order
<u>DeleteOrderShort</u>	Deletes Sell Limit/Stop order
Trade Volume Methods	
<u>LotOpenLong</u>	Gets trade volume for buy operation
<u>LotOpenShort</u>	Gets trade volume for sell operation
<u>LotReverse</u>	Gets trade volume for position reverse operation
Trade History Methods	
<u>PrepareHistoryDate</u>	Sets starting date for trade history tracking
<u>HistoryPoint</u>	Creates a checkpoint of trade history (saves number of positions, orders, deals and historical orders)
<u>CheckTradeState</u>	Compares the current state with the saved one and calls the corresponding event handler
Event flags	
<u>WaitEvent</u>	Sets the trading event waiting flag
<u>NoWaitEvent</u>	Resets the trading event waiting flag
Trade Event Processing Methods	
<u>TradeEventPositionStopTake</u>	Event handler of the "Position Stop Loss/Take Profit triggered" event
<u>TradeEventOrderTriggered</u>	Event handler of the "Pending Order Triggered" event
<u>TradeEventPositionOpened</u>	Event handler of the "Position Opened" event
<u>TradeEventPositionVolumeChanged</u>	Event handler of the "Position Volume Changed" event
<u>TradeEventPositionModified</u>	Event handler of the "Position Modified" event
<u>TradeEventPositionClosed</u>	Event handler of the "Position Closed" event
<u>TradeEventOrderPlaced</u>	Event handler of the "Pending Order Placed" event
<u>TradeEventOrderModified</u>	Event handler of the "Pending Order Modified" event
<u>TradeEventOrderDeleted</u>	Event handler of the "Pending Order Deleted" event
<u>TradeEventNotIdentified</u>	Event handler of the non-identified event

Service methods	
TimeframeAdd	Adds a timeframe to track
TimeframesFlags	Forms timeframe flags
SelectPosition	Selects a position to work with

Methods inherited from class CObject

Prev, Prev, Next, Next, [Save](#), [Load](#), [Type](#), [Compare](#)

Methods inherited from class CExpertBase

[InitPhase](#), [TrendType](#), [UsedSeries](#), [EveryTick](#), [Open](#), [High](#), [Low](#), [Close](#), [Spread](#), [Time](#), [TickVolume](#), [RealVolume](#), [Symbol](#), [Period](#), [Magic](#), [SetMarginMode](#), [SetPriceSeries](#), [SetOtherSeries](#)

Init

Class instance initialization method.

```
bool Init(  
    string          symbol,          // symbol  
    ENUM_TIMEFRAMES period,          // timeframe  
    bool            every_tick,      // flag  
    ulong           magic            // Expert Advisor identifier  
)
```

Parameters

symbol

[in] Symbol.

period

[in] Timeframe from [ENUM_TIMEFRAMES](#) enumeration.

every_tick

[in] Flag.

magic

[in] Expert Advisor ID (Magic number).

Return Value

None.

Note

If *every_tick* is set to true, the [Processing\(\)](#) method is called at each tick of the working symbol. otherwise, the [Processing\(\)](#) is called only when a new bar is formed on the working timeframe of the EA's working symbol.

Magic

Sets the Expert Advisor ID (magic).

```
void Magic(  
    ulong value    // new value  
)
```

Parameters

value

[in] New value of Expert Advisor ID.

Return Value

None.

Note

If EA's identifier is changed, the same identifier is assigned to all auxiliary objects.

Implementation

```
//+-----+  
//| Sets magic number for object and its dependent objects |  
//| INPUT:  value - new value of magic number.           |  
//| OUTPUT: no.                                           |  
//| REMARK: no.                                           |  
//+-----+  
void CExpert::Magic(ulong value)  
{  
    if(m_trade!=NULL)    m_trade.SetExpertMagicNumber(value);  
    if(m_signal!=NULL)   m_signal.Magic(value);  
    if(m_money!=NULL)    m_money.Magic(value);  
    if(m_trailing!=NULL) m_trailing.Magic(value);  
    /---  
    CExpertBase::Magic(value);  
}
```

InitSignal

Initializes trading signal object.

```
virtual bool InitSignal(  
    CExpertSignal*    signal=NULL,        // pointer  
)
```

Parameters

signal

[in] Pointer to [CExpertSignal](#) class object (or its descendant).

Return Value

true - successful, otherwise - false.

Note

If signal is NULL, the [CExpertSignal](#) class will be used for initialization (it does nothing).

InitTrailing

Initializes trailing stop object.

```
virtual bool InitTrailing(  
    CExpertTrailing*   trailing=NULL,           // pointer  
)
```

Parameters

trailing

[in] Pointer to [CExpertTrailing](#) class object (or its descendant).

Return Value

true - successful, otherwise - false.

Note

If trailing is NULL, the [ExpertTrailing](#) class will be used for initialization (it does nothing).

InitMoney

Initializes the money management object.

```
virtual bool InitMoney(  
    CExpertMoney* money=NULL, // pointer  
)
```

Parameters

money

[in] Pointer to [CExpertMoney](#) class object (or its descendant).

Return Value

true - successful, otherwise - false.

Note

If money is NULL, the [CExpertMoney](#) class will be used for initialization (it uses the minimum lot).

InitTrade

Initializes the trade object.

```
virtual bool InitTrade(  
    ulong          magic,          // identifier  
    CExpertTrade*  trade=NULL     // pointer  
)
```

Parameters

magic

[in] Expert Advisor ID (will be used in trade requests).

trade

[in] Pointer to trade object.

Return Value

true - successful, otherwise - false.

Deinit

Class instance deinitialization method.

```
virtual void Deinit()
```

Return Value

None.

OnTickProcess

Sets the [OnTick](#) event handling flag.

```
void OnTickOProcess(  
    bool    value    // flag  
)
```

Parameters

value

[in] [OnTick](#) event handling flag.

Return Value

None.

Note

If the flag is true, the [OnTick](#) event is handled. By default, the flag is set to true.

OnTradeProcess

Sets the [OnTrade](#) event handling flag.

```
void OnTradeProcess(  
    bool    value    // flag  
)
```

Parameters

value

[in] [OnTrade](#) event handling flag.

Return Value

None.

Note

If the flag is true, the [OnTrade](#) event is handled. By default, the flag is set to false.

OnTimerProcess

Sets the [OnTimer](#) event handling flag.

```
void OnTimerProcess(  
    bool    value    // flag  
)
```

Parameters

value

[in] [OnTimer](#) event handling flag.

Return Value

None.

Note

If the flag is true, the [OnTimer](#) event is handled. By default, the flag is set to false.

OnChartEventProcess

Sets a flag to handle the [OnChartEvent](#) event.

```
void OnChartEventProcess (
    bool    value    // flag
)
```

Parameters

value

[in] Flag to handle the [OnChartEvent](#) event.

Return Value

None.

Note

If the flag is true, the [OnChartEvent](#) event is handled. By default, the flag is set to false.

OnBookEventProcess

Sets a flag to handle the [OnBookEvent](#) event.

```
void OnChartEventProcess (
    bool    value    // flag
)
```

Parameters

value

[in] Flag to handle the [OnBookEvent](#) event.

Return Value

None.

Note

If the flag is true, the [OnBookEvent](#) event is handled. By default, the flag is set to false.

MaxOrders (Get Method)

Gets the maximum amount of allowed orders.

```
int MaxOrders()
```

Return Value

Maximum amount of allowed orders.

MaxOrders (Set Method)

Sets the maximum amount of allowed orders.

```
void MaxOrders(  
    int    max_orders    // amount of orders  
)
```

Parameters

max_orders

[in] New value of maximum amount of allowed orders.

Return Value

None.

Note

By default, the maximum amount of allowed orders is equal to 1.

Signal

Gets the pointer to the trade signal object.

```
CExpertSignal* Signal() const
```

Return Value

Pointer to the trade signal object.

ValidationSettings

Checks the settings.

```
virtual bool ValidationSettings()
```

Return Value

true - successful, otherwise - false.

Note

It also checks the settings of all the Expert Advisor objects.

InitIndicators

Initializes necessary indicators and timeseries.

```
virtual bool InitIndicators(  
    CIndicators* indicators=NULL    // pointer  
)
```

Parameters

indicators

[in] Pointer to collection of indicators and timeseries.

Return Value

true - successful completion, otherwise - false.

Note

The timeseries are initialized if the object uses a symbol or timeframe other than the one defined in the initialization.

Indicators and timeseries of all auxiliary EA objects are initialized.

OnTick

[OnTick](#) event handler.

```
virtual void OnTick()
```

Return Value

None.

OnTrade

[OnTrade](#) event handler.

```
virtual void OnTrade()
```

Return Value

None.

OnTimer

[OnTimer](#) event handler.

```
virtual void OnTimer ()
```

Return Value

None.

OnChartEvent

OnChartEvent event handler.

```
virtual void OnChartEvent(  
    const int      id,          // event id  
    const long&    lparam,      // long type event parameter  
    const double   dparam,      // double type event parameter  
    const string   sparam       // string type event parameter  
)
```

Parameters

id

[in] Event ID.

lparam

[in] Event parameter of long type.

dparam

[in] Event parameter of double type.

sparam

[in] Event parameter of string type.

Return Value

None.

OnBookEvent

[OnBookEvent](#) event handler.

```
virtual void OnBookEvent(  
    const string&    symbol        // symbol  
)
```

Parameters

symbol

[in] Symbol of [OnBookEvent](#) event.

Return Value

None.

InitParameters

Initializes parameters of Expert Advisor.

```
virtual bool InitParameters()
```

Return Value

true - successful, otherwise - false.

Note

The InitParameters() function of [CExpert](#) base class does nothing and always returns true.

DeinitTrade

Deinitializes trade object.

```
virtual void DeinitTrade()
```

Return Value

None.

DeinitSignal

Deinitializes trade signal object.

```
virtual void DeinitSignal()
```

Return Value

None.

DeinitTrailing

Deinitializes trailing object.

```
virtual void DeinitTrailing()
```

Return Value

None.

DeinitMoney

Deinitializes money management object.

```
virtual void DeinitMoney()
```

Return Value

None.

DeinitIndicators

Deinitializes indicators and timeseries.

```
virtual void DeinitIndicators ()
```

Return Value

None.

Note

Indicators and timeseries of all auxiliary EA objects are deinitialized.

Refresh

Updates all necessary data.

```
virtual bool Refresh()
```

Return Value

true - further tick processing is needed, otherwise - false.

Note

It allows to determine the need of tick processing. If it is needed, it updates all quotes and timeseries and indicators data and returns true.

Implementation

```
//+-----+
//| Refreshing data for processing |
//| INPUT: no. |
//| OUTPUT: true-if successful, false otherwise. |
//| REMARK: no. |
//+-----+
bool CExpert::Refresh()
{
    MqlDateTime time;
    //-- refresh rates
    if(!m_symbol.RefreshRates()) return(false);
    //-- check need processing
    TimeToStruct(m_symbol.Time(),time);
    if(m_period_flags!=WRONG_VALUE && m_period_flags!=0)
        if((m_period_flags & TimeframesFlags(time))==0) return(false);
    m_last_tick_time=time;
    //-- refresh indicators
    m_indicators.Refresh();
    //-- ok
    return(true);
}
```

Processing

Main processing algorithm.

```
virtual bool Processing()
```

Return Value

true - trade operation has been executed, otherwise - false.

Note

It does the following steps:

1. Checks the presence of the opened position on the symbol. If there is no opened position, skip steps 2, 3, and 4.
2. Checks conditions to reverse opened position ([CheckReverse\(\)](#) method). If position has been "reversed", exit.
3. Checks conditions to close position ([CheckClose\(\)](#) method). If position has been closed, skip step 4.
4. Checks conditions to modify position parameters ([CheckTrailingStop\(\)](#) method). If position parameters have been modified, exit.
5. Check the presence of pending orders on the symbol. If there is no any pending order, go to step 9.
6. Checks condition to delete order ([CheckDeleteOrderLong\(\)](#) for buy pending orders or [CheckDeleteOrderShort\(\)](#) for sell pending orders). If the order has been deleted, go to step 9.
7. Check conditions to modify pending order parameters ([CheckTrailingOrderLong\(\)](#) for buy orders or [CheckTrailingOrderShort\(\)](#) for sell orders). If the order parameters have been modified, exit.
8. Exit.
9. Checks conditions to open position ([CheckOpen\(\)](#) method).

If you want to implement your own algorithm, you need to override the [Processing\(\)](#) method of the descendant class.

Implementation

```

//+-----+
//| Main function                                     |
//| INPUT:  no.                                       |
//| OUTPUT: true-if any trade operation processed, false otherwise. |
//| REMARK: no.                                       |
//+-----+
bool CExpert::Processing()
{
//--- check if open positions
    if(m_position.Select(m_symbol.Name()))
    {
        //--- open position is available
        //--- check the possibility of reverse the position
        if(CheckReverse()) return(true);
        //--- check the possibility of closing the position/delete pending orders
        if(!CheckClose())
        {
            //--- check the possibility of modifying the position
            if(CheckTrailingStop()) return(true);
            //--- return without operations
            return(false);
        }
    }
//--- check if placed pending orders
    int total=OrdersTotal();
    if(total!=0)
    {
        for(int i=total-1;i>=0;i--)
        {
            m_order.SelectByIndex(i);
            if(m_order.Symbol()!=m_symbol.Name()) continue;
            if(m_order.OrderType()==ORDER_TYPE_BUY_LIMIT || m_order.OrderType()==ORDER_T
            {
                //--- check the ability to delete a pending order to buy
                if(CheckDeleteOrderLong()) return(true);
                //--- check the possibility of modifying a pending order to buy
                if(CheckTrailingOrderLong()) return(true);
            }
            else
            {
                //--- check the ability to delete a pending order to sell
                if(CheckDeleteOrderShort()) return(true);
                //--- check the possibility of modifying a pending order to sell
                if(CheckTrailingOrderShort()) return(true);
            }
            //--- return without operations
            return(false);
        }
    }
//--- check the possibility of opening a position/setting pending order
    if(CheckOpen()) return(true);
//--- return without operations
    return(false);
}

```

SelectPosition

Selects a position to work with.

```
void SelectPosition()
```

Return Value

No.

Implementation

```
//+-----+
//| Position select                                     |
//| INPUT:  no.                                         |
//| OUTPUT: no.                                         |
//| REMARK: no.                                         |
//+-----+
bool CExpert::SelectPosition(void)
{
    bool res=false;
//---
    if(m_margin_mode==ACCOUNT_MARGIN_MODE_RETAIL_HEDGING)
        res=m_position.SelectByMagic(m_symbol.Name(),m_magic);
    else
        res=m_position.Select(m_symbol.Name());
//---
    return(res);
}
```

CheckOpen

Checks conditions to open a position.

```
virtual bool CheckOpen()
```

Return Value

true - a trade operation has been executed, otherwise - false.

Note

It checks the necessity to open long ([CheckOpenLong\(\)](#)) and short ([CheckOpenShort\(\)](#)) positions.

Implementation

```
//+-----+
//| Check for position open or limit/stop order set |
//| INPUT:  no. |
//| OUTPUT: true-if trade operation processed, false otherwise. |
//| REMARK: no. |
//+-----+
bool CExpert::CheckOpen()
{
    if(CheckOpenLong()) return(true);
    if(CheckOpenShort()) return(true);
    //--- return without operations
    return(false);
}
```

CheckOpenLong

Checks necessity and conditions to open long position.

```
virtual bool CheckOpenLong()
```

Return Value

true - a trade operation has been executed, otherwise - false.

Note

It checks the necessity to open a long position (CheckOpenLong() method of Signal object) and does that with the parameters set by Signal object ([OpenLong\(\)](#) method) if the conditions are met.

Implementation

```
//+-----+
//| Check for long position open or limit/stop order set |
//| INPUT:  no. |
//| OUTPUT: true-if trade operation processed, false otherwise. |
//| REMARK: no. |
//+-----+
bool CExpert::CheckOpenLong()
{
    double price=EMPTY_VALUE;
    double sl=0.0;
    double tp=0.0;
    datetime expiration=TimeCurrent();
    //-- check signal for long enter operations
    if(m_signal.CheckOpenLong(price,sl,tp,expiration))
    {
        if(!m_trade.SetOrderExpiration(expiration))
        {
            m_expiration=expiration;
        }
        return(OpenLong(price,sl,tp));
    }
    //-- return without operations
    return(false);
}
```

CheckOpenShort

Checks necessity and conditions to open a short position.

```
virtual bool CheckOpenShort()
```

Return Value

true - a trade operation has been executed, otherwise - false.

Note

It checks the necessity to open a short position (CheckOpenShort() method of Signal object) and does that with the parameters set by Signal object ([OpenShort\(\)](#) method) if the conditions are met.

Implementation

```
//+-----+
//| Check for short position open or limit/stop order set |
//| INPUT:  no. |
//| OUTPUT: true-if trade operation processed, false otherwise. |
//| REMARK: no. |
//+-----+
bool CExpert::CheckOpenShort()
{
    double price=EMPTY_VALUE;
    double sl=0.0;
    double tp=0.0;
    datetime expiration=TimeCurrent();
//--- check signal for short enter operations
    if(m_signal.CheckOpenShort(price,sl,tp,expiration))
    {
        if(!m_trade.SetOrderExpiration(expiration))
        {
            m_expiration=expiration;
        }
        return(OpenShort(price,sl,tp));
    }
//--- return without operations
    return(false);
}
```

OpenLong

Opens a long position.

```
virtual bool OpenLong(  
    double price,    // price  
    double sl,       // Stop Loss  
    double tp        // Take Profit  
)
```

Parameters

price

[in] Market entry price.

sl

[in] Stop Loss price.

tp

[in] Take Profit price.

Return Value

true - trade operation has been executed, otherwise - false.

Note

It gets trading volume ([LotOpenLong\(...\)](#) method) and opens a long position (Buy() method of Trade object) if trading volume is not equal to 0.

Implementation

```
//+-----+  
//| Long position open or limit/stop order set |  
//| INPUT:  price - price,                    |  
//|         sl    - stop loss,                |  
//|         tp    - take profit.              |  
//| OUTPUT: true-if trade operation processed, false otherwise. |  
//| REMARK: no.                              |  
//+-----+  
bool CExpert::OpenLong(double price,double sl,double tp)  
{  
    if(price==EMPTY_VALUE) return(false);  
    //--- get lot for open  
    double lot=LotOpenLong(price,sl);  
    //--- check lot for open  
    if(lot==0.0) return(false);  
    //---  
    return(m_trade.Buy(lot,price,sl,tp));  
}
```

OpenShort

Opens a short position.

```
virtual bool OpenShort(
    double price, // price
    double sl,    // Stop Loss
    double tp     // Take Profit
)
```

Parameters

price

[in] Market entry price.

sl

[in] Stop Loss price.

tp

[in] Take Profit price.

Return Value

true - trade operation has been executed, otherwise - false.

Note

It gets trading volume ([LotOpenShort\(\)](#) method) and opens a short position (by calling Sell method of Trade object) if trading volume is not equal to 0.

Implementation

```
//+-----+
//| Short position open or limit/stop order set |
//| INPUT:  price - price,                      |
//|         sl    - stop loss,                  |
//|         tp    - take profit.                |
//| OUTPUT: true-if trade operation successful, false otherwise. |
//| REMARK: no.                                |
//+-----+
bool CExpert::OpenShort(double price,double sl,double tp)
{
    if(price==EMPTY_VALUE) return(false);
//--- get lot for open
    double lot=LotOpenShort(price,sl);
//--- check lot for open
    if(lot==0.0) return(false);
//---
    return(m_trade.Sell(lot,price,sl,tp));
}
```

CheckReverse

Checks necessity and conditions to reverse an open position.

```
virtual bool CheckReverse()
```

Return Value

true - a trade operation has been executed, otherwise - false.

Note

It checks the necessity to reverse long ([CheckReverseLong\(\)](#)) and short ([CheckReverseShort\(\)](#)) positions.

Implementation

```
//+-----+
//| Check for position reverse |
//| INPUT:  no.                |
//| OUTPUT: true-if trade operation processed, false otherwise. |
//| REMARK: no.                |
//+-----+
bool CExpert::CheckReverse()
{
    if(m_position.PositionType()==POSITION_TYPE_BUY)
    {
        //--- check the possibility of reverse the long position
        if(CheckReverseLong()) return(true);
    }
    else
        //--- check the possibility of reverse the short position
        if(CheckReverseShort()) return(true);
    //--- return without operations
    return(false);
}
```

CheckReverseLong

Checks necessity and conditions to reverse a long position.

```
virtual bool CheckReverseLong()
```

Return Value

true - a trade operation has been executed, otherwise - false.

Note

It checks the necessity to reverse a long position (CheckReverseLong() method of Signal object) and perform reverse operation of the current long position with the parameters set by Signal object ([ReverseLong\(...\)](#) method) if the conditions are met.

Implementation

```
//+-----+
//| Check for long position reverse |
//| INPUT:  no. |
//| OUTPUT: true-if trade operation processed, false otherwise. |
//| REMARK: no. |
//+-----+
bool CExpert::CheckReverseLong()
{
    double price=EMPTY_VALUE;
    double sl=0.0;
    double tp=0.0;
    datetime expiration=TimeCurrent();
    //--- check signal for long reverse operations
    if(m_signal.CheckReverseLong(price,sl,tp,expiration)) return(ReverseLong(price,sl,tp,expiration));
    //--- return without operations
    return(false);
}
```

CheckReverseShort

Checks necessity and conditions to reverse a short position.

```
virtual bool CheckReverseLong()
```

Return Value

true - a trade operation has been executed, otherwise - false.

Note

It checks the necessity to reverse a short position (CheckReverseShort() method of Signal object) and perform reverse operation of the current short position with the parameters set by Signal object ([ReverseShort\(\)](#) method) if the conditions are met.

Implementation

```
//+-----+
//| Check for short position reverse |
//| INPUT:  no.                      |
//| OUTPUT: true-if trade operation processed, false otherwise. |
//| REMARK: no.                      |
//+-----+
bool CExpert::CheckReverseShort()
{
    double price=EMPTY_VALUE;
    double sl=0.0;
    double tp=0.0;
    datetime expiration=TimeCurrent();
    //-- check signal for short reverse operations
    if(m_signal.CheckReverseShort(price,sl,tp,expiration)) return(ReverseShort(price,sl,expiration));
    //-- return without operations
    return(false);
}
```

ReverseLong

Performs reverse operation of a long position.

```
virtual bool  ReverseLong(  
    double    price,      // price  
    double    sl,         // Stop Loss  
    double    tp          // Take Profit  
)
```

Parameters

price

[in] Market entry price.

sl

[in] Stop Loss price.

tp

[in] Take Profit price.

Return Value

true - trade operation has been executed, otherwise - false.

Note

It gets the position reverse volume ([LotReverse\(\)](#) method) and reverses a long position (Sell() method of Trade object) if trading volume is not equal to 0.

In the "hedging" mode of position accounting, position reversal is performed as the closure of the existing position and opening of a new opposite one with the remaining volume.

Implementation

```
//+-----+
//| Long position reverse |
//| INPUT:  price - price, |
//|         sl    - stop loss, |
//|         tp    - take profit. |
//| OUTPUT: true-if trade operation processed, false otherwise. |
//| REMARK: no. |
//+-----+
bool CExpert::ReverseLong(double price,double sl,double tp)
{
    if(price==EMPTY_VALUE)
        return(false);
//--- get lot for reverse
    double lot=LotReverse(sl);
//--- check lot
    if(lot==0.0)
        return(false);
//---
    bool result=true;
    if(m_margin_mode==ACCOUNT_MARGIN_MODE_RETAIL_HEDGING)
    {
        //--- first close existing position
        lot-=m_position.Volume();
        result=m_trade.PositionCloseByTicket(m_position.Identifier());
    }
    if(result)
        result=m_trade.Sell(lot,price,sl,tp);
//---
    return(result);
}
```

ReverseShort

Performs reverse operation of a short position.

```
virtual bool ReverseShort(  
    double price, // price  
    double sl,    // Stop Loss  
    double tp     // Take Profit  
)
```

Parameters

price

[in] Market entry price.

sl

[in] Stop Loss price.

tp

[in] Take Profit price.

Return Value

true - trade operation has been executed, otherwise - false.

Note

It gets position reverse volume ([LotReverse\(...\)](#) method) and perform trade operation of the short position reverse (Buy() method of Trade object) if trading volume is not equal to 0.

In the "hedging" mode of position accounting, position reversal is performed as the closure of the existing position and opening of a new opposite one with the remaining volume.

Implementation

```
//+-----+
//| Short position reverse                               |
//| INPUT:  price - price,                               |
//|         sl    - stop loss,                           |
//|         tp    - take profit.                         |
//| OUTPUT: true-if trade operation processed, false otherwise. |
//| REMARK: no.                                           |
//+-----+
bool CExpert::ReverseLong(double price,double sl,double tp)
{
    if(price==EMPTY_VALUE)
        return(false);
//--- get lot for reverse
    double lot=LotReverse(sl);
//--- check lot
    if(lot==0.0)
        return(false);
//---
    bool result=true;
    if(m_margin_mode==ACCOUNT_MARGIN_MODE_RETAIL_HEDGING)
    {
        //--- first close existing position
        lot-=m_position.Volume();
        result=m_trade.PositionCloseByTicket(m_position.Identifier());
    }
    if(result)
        result=m_trade.Sell(lot,price,sl,tp);
//---
    return(result);
}
```

CheckClose

Checks conditions to close position.

```
virtual bool CheckClose()
```

Return Value

true - trade operation has been executed, otherwise - false.

Note

1. It checks Expert Advisor Stop Out conditions (CheckClose() method of money management object). If condition is satisfied, it closes the position, deletes all orders ([CloseAll\(\)](#)), and exits.
2. It checks conditions to close long or short position ([CheckCloseLong\(\)](#) or [CheckCloseShort\(\)](#) methods) and if position is closed, it deletes all orders ([DeleteOrders\(\)](#) method).

Implementation

```
//+-----+
//| Check for position close or limit/stop order delete |
//| INPUT:  no. |
//| OUTPUT: true-if trade operation processed, false otherwise. |
//| REMARK: no. |
//+-----+
bool CExpert::CheckClose()
{
    double lot;
    //--- position must be selected before call
    if((lot=m_money.CheckClose(GetPointer(m_position)))!=0.0)
        return(CloseAll(lot));
    //--- check for position type
    if(m_position.PositionType()==POSITION_TYPE_BUY)
    {
        //--- check the possibility of closing the long position / delete pending orders
        if(CheckCloseLong())
        {
            DeleteOrders();
            return(true);
        }
    }
    else
    {
        //--- check the possibility of closing the short position / delete pending orders
        if(CheckCloseShort())
        {
            DeleteOrders();
            return(true);
        }
    }
    //--- return without operations
    return(false);
}
```

CheckCloseLong

Checks conditions to close a long position.

```
virtual bool CheckCloseLong()
```

Return Value

true - trade operation has been executed, otherwise - false.

Note

It checks conditions to close a long position (CheckCloseLong() method of Signal object) and if they are satisfied, it closes the open position ([CloseLong\(...\)](#) method).

Implementation

```
//+-----+
//| Check for long position close or limit/stop order delete |
//| INPUT:  no. |
//| OUTPUT: true-if trade operation processed, false otherwise. |
//| REMARK: no. |
//+-----+
bool CExpert::CheckCloseLong()
{
    double price=EMPTY_VALUE;
    ///--- check for long close operations
    if(m_signal.CheckCloseLong(price))
        return(CloseLong(price));
    ///--- return without operations
    return(false);
}
```

CheckCloseShort

Checks conditions to close a short position.

```
virtual bool CheckCloseShort()
```

Return Value

true - trade operation has been executed, otherwise - false.

Note

It checks conditions to close a short position (CheckCloseShort() method of Signal object) and if they are satisfied, it closes the position ([CloseShort\(\)](#) method).

Implementation

```
//+-----+
//| Check for short position close or limit/stop order delete |
//| INPUT:  no. |
//| OUTPUT: true-if trade operation processed, false otherwise. |
//| REMARK: no. |
//+-----+
bool CExpert::CheckCloseShort()
{
    double price=EMPTY_VALUE;
    ///--- check for short close operations
    if(m_signal.CheckCloseShort(price))
        return(CloseShort(price));
    ///--- return without operations
    return(false);
}
```

CloseAll

It performs partial of full position closing.

```
virtual bool CloseAll(
    double lot // lot
)
```

Parameters

lot

[in] Number of lots to reduce the position.

Return Value

true - trade operation has been executed, otherwise - false.

Note

In the "netting" mode, a position is closed using the CExpertTrade::Buy or CExpertTrade::Sell methods. In the "hedging" mode, the CTrade::PositionClose method is used, which can also be used on accounts with the netting mode. The [DeleteOrders\(\)](#) method is used to delete orders.

Implementation

```
//+-----+
//| Position close and orders delete |
//| INPUT: lot - volume for close. |
//| OUTPUT: true-if trade operation processed, false otherwise. |
//| REMARK: no. |
//+-----+
bool CExpert::CloseAll(double lot)
{
    bool result=false;
    //-- check for close operations
    if(m_margin_mode==ACCOUNT_MARGIN_MODE_RETAIL_HEDGING)
        result=m_trade.PositionCloseByTicket(m_position.Identifier());
    else
    {
        if(m_position.PositionType()==POSITION_TYPE_BUY)
            result=m_trade.Sell(lot,0,0,0);
        else
            result=m_trade.Buy(lot,0,0,0);
    }
    result|=DeleteOrders();
    //--
    return(result);
}
```

Close

Closes the opened position.

```
virtual bool Close()
```

Return Value

true - trade operation has been executed, otherwise - false.

Note

Closes the position (PositionClose() method of CTrade class object).

Implementation

```
//+-----+
//| Position close                               |
//| INPUT:  no.                                  |
//| OUTPUT: true-if trade operation processed, false otherwise. |
//| REMARK: no.                                  |
//+-----+
bool CExpert::Close()
{
    return(m_trade.PositionClose(m_symbol.Name()));
}
```

CloseLong

Closes the long position.

```
virtual bool CloseLong(  
    double price // price  
)
```

Parameters

price

[in] Market entry price.

Return Value

true - trade operation has been executed, otherwise - false.

Note

In the "netting" mode, a position is closed using the CExpertTrade::Buy or CExpertTrade::Sell methods. In the "hedging" mode, the CTrade::PositionCloseByTicket method is used.

Implementation

```
//+-----+  
//| Long position close |  
//| INPUT: price - price for close. |  
//| OUTPUT: true-if trade operation processed, false otherwise. |  
//| REMARK: no. |  
//+-----+  
bool CExpert::CloseLong(double price)  
{  
    bool result=false;  
    //---  
    if(price==EMPTY_VALUE)  
        return(false);  
    if(m_margin_mode==ACCOUNT_MARGIN_MODE_RETAIL_HEDGING)  
        result=m_trade.PositionCloseByTicket(m_position.Identifier());  
    else  
        result=m_trade.Sell(m_position.Volume(),price,0,0);  
    //---  
    return(result);  
}
```

CloseShort

Closes the short position.

```
virtual bool CloseShort(  
    double price // price  
)
```

Parameters

price

[in] Market entry price.

Return Value

true - trade operation has been executed, otherwise - false.

Note

In the "netting" mode, a position is closed using the CExpertTrade::Buy or CExpertTrade::Sell methods. In the "hedging" mode, the CTrade::PositionCloseByTicket method is used.

Implementation

```
//+-----+  
//| Short position close |  
//| INPUT: price - price for close. |  
//| OUTPUT: true-if trade operation successful, false otherwise. |  
//| REMARK: no. |  
//+-----+  
bool CExpert::CloseShort(double price)  
{  
    bool result=false;  
    //---  
    if(price==EMPTY_VALUE)  
        return(false);  
    if(m_margin_mode==ACCOUNT_MARGIN_MODE_RETAIL_HEDGING)  
        result=m_trade.PositionCloseByTicket(m_position.Identifier());  
    else  
        result=m_trade.Buy(m_position.Volume(),price,0,0);  
    //---  
    return(result);  
}
```

CheckTrailingStop

It checks Trailing Stop conditions of the opened position.

```
virtual bool CheckTrailingStop()
```

Return Value

true - a trade operation has been executed, otherwise - false.

Note

It checks Trailing Stop conditions of the opened position ([CheckTrailingStopLong\(\)](#) or [CheckTrailingStopShort\(\)](#) for long and short positions).

Implementation

```
//+-----+
//| Check for trailing stop/profit position |
//| INPUT:  no. |
//| OUTPUT: true-if trade operation processed, false otherwise. |
//| REMARK: no. |
//+-----+
bool CExpert::CheckTrailingStop()
{
    //--- position must be selected before call
    if(m_position.PositionType()==POSITION_TYPE_BUY)
    {
        //--- check the possibility of modifying the long position
        if(CheckTrailingStopLong()) return(true);
    }
    else
    {
        //--- check the possibility of modifying the short position
        if(CheckTrailingStopShort()) return(true);
    }
    //--- return without operations
    return(false);
}
```

CheckTrailingStopLong

It checks Trailing Stop conditions of the opened long position.

```
virtual bool CheckTrailingStopLong()
```

Return Value

true - trade operation has been executed, otherwise - false.

Note

It checks Trailing Stop conditions of the opened long position (CheckTrailingStopLong(...) method of Expert Trailing object). If conditions are satisfied, it modifies the position parameters ([TrailingStopLong\(...\)](#) method).

Implementation

```
//+-----+
//| Check for trailing stop/profit long position |
//| INPUT:  no.                                |
//| OUTPUT: true-if trade operation processed, false otherwise. |
//| REMARK: no.                                |
//+-----+
bool CExpert::CheckTrailingStopLong()
{
    double sl=EMPTY_VALUE;
    double tp=EMPTY_VALUE;
    //-- check for long trailing stop operations
    if(m_trailing.CheckTrailingStopLong(GetPointer(m_position),sl,tp))
    {
        if(sl==EMPTY_VALUE) sl=m_position.StopLoss();
        if(tp==EMPTY_VALUE) tp=m_position.TakeProfit();
        //-- long trailing stop operations
        return(TrailingStopLong(sl,tp));
    }
    //-- return without operations
    return(false);
}
```

CheckTrailingStopShort

It checks Trailing Stop conditions of the opened short position.

```
virtual bool CheckTrailingStopShort()
```

Return Value

true - trade operation has been executed, otherwise - false.

Note

It checks Trailing Stop conditions of the opened short position (CheckTrailingStopShort(...) method of Expert Trailing object). If conditions are satisfied, it modifies the position parameters ([TrailingStopShort\(...\)](#) method).

Implementation

```
//+-----+
//| Check for trailing stop/profit short position |
//| INPUT:  no. |
//| OUTPUT: true-if trade operation processed, false otherwise. |
//| REMARK: no. |
//+-----+
bool CExpert::CheckTrailingStopShort()
{
    double sl=EMPTY_VALUE;
    double tp=EMPTY_VALUE;
    //-- check for short trailing stop operations
    if(m_trailing.CheckTrailingStopShort(GetPointer(m_position),sl,tp))
    {
        if(sl==EMPTY_VALUE) sl=m_position.StopLoss();
        if(tp==EMPTY_VALUE) tp=m_position.TakeProfit();
        //-- short trailing stop operations
        return(TrailingStopShort(sl,tp));
    }
    //-- return without operations
    return(false);
}
```

TrailingStopLong

It modifies parameters of the opened long position.

```
virtual bool TrailingStopLong(  
    double sl,      // Stop Loss  
    double tp,      // Take Profit  
)
```

Parameters

sl

[in] Stop Loss price.

tp

[in] Take Profit price.

Return Value

true - trade operation has been executed, otherwise - false.

Note

The function modifies parameters of the opened long position (PositionModify(...) method of CTrade class object).

Implementation

```
//+-----+  
//| Trailing stop/profit long position |  
//| INPUT:  sl - new stop loss,       |  
//|         tp - new take profit.     |  
//| OUTPUT: true-if trade operation successful, false otherwise. |  
//| REMARK: no.                      |  
//+-----+  
bool CExpert::TrailingStopLong(double sl,double tp)  
{  
    return(m_trade.PositionModify(m_symbol.Name(),sl,tp));  
}
```

TrailingStopShort

It modifies parameters of the opened short position.

```
virtual bool TrailingStopLong(  
    double sl,    // Stop Loss  
    double tp,    // Take Profit  
)
```

Parameters

sl

[in] Stop Loss price.

tp

[in] Take Profit price.

Return Value

true - trade operation has been executed, otherwise - false.

Note

The function modifies parameters of the opened short position (PositionModify(...) method of CTrade class object).

Implementation

```
//+-----+  
//| Trailing stop/profit short position |  
//| INPUT:  sl - new stop loss,         |  
//|         tp - new take profit.       |  
//| OUTPUT: true-if trade operation successful, false otherwise. |  
//| REMARK: no.                        |  
//+-----+  
bool CExpert::TrailingStopShort(double sl,double tp)  
{  
    return(m_trade.PositionModify(m_symbol.Name(),sl,tp));  
}
```

CheckTrailingOrderLong

Checks Trailing Stop conditions of Buy Limit/Stop trailing order.

```
virtual bool CheckTrailingOrderLong()
```

Return Value

true - trade operation has been executed, otherwise - false.

Note

It checks Trailing Stop conditions for buy limit/stop trailing order (CheckTrailingOrderLong() method of Trade Signals object) and modifies the order parameters if necessary ([TrailingOrderLong\(...\)](#) method).

Implementation

```
//+-----+
//| Check for trailing long limit/stop order |
//| INPUT:  no.                             |
//| OUTPUT: true-if trade operation processed, false otherwise. |
//| REMARK: no.                             |
//+-----+
bool CExpert::CheckTrailingOrderLong()
{
    double price;
    //--- check the possibility of modifying the long order
    if(m_signal.CheckTrailingOrderLong(GetPointer(m_order),price))
        return(TrailingOrderLong(m_order.PriceOpen()-price));
    //--- return without operations
    return(false);
}
```

CheckTrailingOrderShort

It checks Trailing Stop conditions of Sell Limit/Stop trailing order.

```
virtual bool CheckTrailingOrderShort()
```

Return Value

true - trade operation has been executed, otherwise - false.

Note

It checks Trailing Stop conditions for sell limit/stop trailing order (CheckTrailingOrderShort() method of Trade Signals object) and modifies the order parameters if necessary ([TrailingOrderShort\(\)](#) method).

Implementation

```
//+-----+
//| Check for trailing short limit/stop order |
//| INPUT:  no.                             |
//| OUTPUT: true-if trade operation processed, false otherwise. |
//| REMARK: no.                             |
//+-----+
bool CExpert::CheckTrailingOrderShort()
{
    double price;
    ///--- check the possibility of modifying the short order
    if(m_signal.CheckTrailingOrderShort(GetPointer(m_order),price))
        return(TrailingOrderShort(m_order.PriceOpen()-price));
    ///--- return without operations
    return(false);
}
```

TrailingOrderLong

It modifies parameters of Buy Limit/Stop trailing order.

```
virtual bool TrailingOrderLong(
    double delta // delta
)
```

Parameters

delta

[in] Price delta.

Return Value

true - trade operation has been executed, otherwise - false.

Note

It modifies parameters of Buy Limit/Stop trailing order (OrderModify(...) method of CTrade class object).

Implementation

```
//+-----+
//| Trailing long limit/stop order |
//| INPUT: delta - price change. |
//| OUTPUT: true-if trade operation successful, false otherwise. |
//| REMARK: no. |
//+-----+
bool CExpert::TrailingOrderLong(double delta)
{
    ulong ticket=m_order.Ticket();
    double price =m_order.PriceOpen()-delta;
    double sl =m_order.StopLoss()-delta;
    double tp =m_order.TakeProfit()-delta;
    //--- modifying the long order
    return(m_trade.OrderModify(ticket,price,sl,tp,m_order.TypeTime(),m_order.TimeExpir
}
```

TrailingOrderShort

It modifies parameters of Sell Limit/Stop trailing order.

```
virtual bool TrailingOrderShort(
    double delta // delta
)
```

Parameters

delta

[in] Price delta.

Return Value

true - trade operation has been executed, otherwise - false.

Note

It modifies parameters of Sell Limit/Stop trailing order (OrderModify(...) method of CTrade class object).

Implementation

```
//+-----+
//| Trailing short limit/stop order |
//| INPUT: delta - price change. |
//| OUTPUT: true-if trade operation successful, false otherwise. |
//| REMARK: no. |
//+-----+
bool CExpert::TrailingOrderShort(double delta)
{
    ulong ticket=m_order.Ticket();
    double price =m_order.PriceOpen()-delta;
    double sl =m_order.StopLoss()-delta;
    double tp =m_order.TakeProfit()-delta;
    //--- modifying the short order
    return(m_trade.OrderModify(ticket,price,sl,tp,m_order.TypeTime(),m_order.TimeExpiration));
}
```

CheckDeleteOrderLong

It checks conditions to delete Buy Limit/Stop order.

```
virtual bool CheckDeleteOrderLong()
```

Return Value

true - trade operation has been executed, otherwise - false.

Note

It checks the order expiration time. It checks conditions to delete the Buy Limit/Stop order (CheckCloseLong(...) method of Signal class object) and deletes the order if condition is satisfied ([DeleteOrderLong\(\)](#) method).

Implementation

```
//+-----+
//| Check for delete long limit/stop order |
//| INPUT: no. |
//| OUTPUT: true-if trade operation processed, false otherwise. |
//| REMARK: no. |
//+-----+
bool CExpert::CheckDeleteOrderLong()
{
    double price;
    //-- check the possibility of deleting the long order
    if(m_expiration!=0 && TimeCurrent()>m_expiration)
    {
        m_expiration=0;
        return(DeleteOrderLong());
    }
    if(m_signal.CheckCloseLong(price))
        return(DeleteOrderLong());
    //-- return without operations
    return(false);
}
```

CheckDeleteOrderShort

It checks conditions to delete Sell Limit/Stop order.

```
virtual bool CheckDeleteOrderShort ()
```

Return Value

true - trade operation has been executed, otherwise - false.

Note

1. It checks the order expiration time.
2. It checks conditions to delete the Sell Limit/Stop order (CheckCloseShort(...) method of Signal class object) and deletes the order if one of the conditions is satisfied ([DeleteOrderShort\(\)](#) method).

Implementation

```
//+-----+
//| Check for delete short limit/stop order |
//| INPUT: no. |
//| OUTPUT: true-if trade operation processed, false otherwise. |
//| REMARK: no. |
//+-----+
bool CExpert::CheckDeleteOrderShort ()
{
    double price;
    //-- check the possibility of deleting the short order
    if(m_expiration!=0 && TimeCurrent()>m_expiration)
    {
        m_expiration=0;
        return(DeleteOrderShort());
    }
    if(m_signal.CheckCloseShort(price))
        return(DeleteOrderShort());
    //-- return without operations
    return(false);
}
```

DeleteOrders

Deletes all orders.

```
virtual bool DeleteOrders()
```

Return Value

true - trade operation has been executed, otherwise - false.

Note

It deletes all orders ([DeleteOrder\(\)](#) for all orders).

Implementation

```
//+-----+
//| Delete all limit/stop orders |
//| INPUT: no. |
//| OUTPUT: true-if trade operation successful, false otherwise. |
//| REMARK: no. |
//+-----+
bool CExpert::DeleteOrders()
{
    bool result=false;
    int total=OrdersTotal();
    //---
    for(int i=total-1;i>=0;i--)
    {
        if(m_order.Select(OrderGetTicket(i)))
        {
            if(m_order.Symbol()!=m_symbol.Name()) continue;
            result|=DeleteOrder();
        }
    }
    //---
    return(result);
}
```

DeleteOrder

Deletes the Limit/Stop order.

```
virtual bool DeleteOrder()
```

Return Value

true - trade operation has been executed, otherwise - false.

Note

It deletes the Limit/Stop order (OrderDelete(...) method of CTrade class object).

Implementation

```
//+-----+
//| Delete limit/stop order                               |
//| INPUT:  no.                                           |
//| OUTPUT: true-if trade operation successful, false otherwise. |
//| REMARK: no.                                           |
//+-----+
bool CExpert::DeleteOrder()
{
    return(m_trade.OrderDelete(m_order.Ticket()));
}
```

DeleteOrderLong

Deletes the Buy Limit/Stop order.

```
virtual bool DeleteOrderLong()
```

Return Value

true - trade operation has been executed, otherwise - false.

Note

It deletes Buy Limit/Stop order (OrderDelete(...) method of CTrade class object).

Implementation

```
//+-----+
//| Delete long limit/stop order |
//| INPUT:  no.                  |
//| OUTPUT: true-if trade operation successful, false otherwise. |
//| REMARK: no.                  |
//+-----+
bool CExpert::DeleteOrderLong()
{
    return(m_trade.OrderDelete(m_order.Ticket()));
}
```

DeleteOrderShort

Deletes the Sell Limit/Stop order.

```
virtual bool DeleteOrderShort ()
```

Return Value

true - trade operation has been executed, otherwise - false.

Note

It deletes the Sell Limit/Stop order (OrderDelete(...) method of CTrade class object).

Implementation

```
//+-----+  
//| Delete short limit/stop order |  
//| INPUT:  no.                   |  
//| OUTPUT: true-if trade operation successful, false otherwise. |  
//| REMARK: no.                   |  
//+-----+  
bool CExpert::DeleteOrderShort ()  
{  
    return(m_trade.OrderDelete(m_order.Ticket()));  
}
```

LotOpenLong

Gets trade volume for buy operation.

```
double LotOpenLong(  
    double price, // price  
    double sl      // Stop Loss  
)
```

Parameters

price

[in] Market entry price.

sl

[in] Stop Loss price.

Return Value

Trade volume (in lots) for buy operation.

Note

It gets trade volume for buy operation (CheckOpenLong(...) method of money management object).

Implementation

```
//+-----+  
//| Method of getting the lot for open long position. |  
//| INPUT:  price - price,                             |  
//|        sl    - stop loss.                         |  
//| OUTPUT: lot for open.                             |  
//| REMARK: no.                                       |  
//+-----+  
double CExpert::LotOpenLong(double price,double sl)  
{  
    return(m_money.CheckOpenLong(price,sl));  
}
```

LotOpenShort

Gets trade volume for sell operation.

```
double LotOpenShort(  
    double price, // price  
    double sl      // Stop Loss  
)
```

Parameters

price

[in] Market entry price.

sl

[in] Stop Loss price.

Return Value

Trade volume (in lots) for sell operation.

Note

It gets trade volume for sell operation (CheckOpenShort(...) method of money management object).

Implementation

```
//+-----+  
//| Method of getting the lot for open short position. |  
//| INPUT:  price - price, |  
//|        sl    - stop loss. |  
//| OUTPUT: lot for open. |  
//| REMARK: no. |  
//+-----+  
double CExpert::LotOpenShort(double price,double sl)  
{  
    return(m_money.CheckOpenShort(price,sl));  
}
```

LotReverse

Gets trade volume for position reverse.

```
double LotReverse(  
    double    sl      // Stop Loss  
)
```

Parameters

sl

[in] Stop Loss price.

Return Value

Trade volume (in lots) for position reverse operation.

Note

It gets trade volume for position reverse operation (CheckReverse(...) method of money management object).

Implementation

```
//+-----+  
//| Method of getting the lot for reverse position. |  
//| INPUT:  sl - stop loss.                        |  
//| OUTPUT: lot for open.                          |  
//| REMARK: no.                                    |  
//+-----+  
double CExpert::LotReverse(double sl)  
{  
    return(m_money.CheckReverse(GetPointer(m_position),sl));  
}
```

PrepareHistoryDate

Sets starting date for tracking of trade history.

```
void PrepareHistoryDate()
```

Note

The trade history tracking period is set from the beginning of the month (but not less than one day).

HistoryPoint

Creates a checkpoint of trade history.

```
void HistoryPoint(  
    bool    from_check_trade=false    // flag  
)
```

Parameters

from_check_trade=false
[in] Flag to avoid recursion.

Note

It saves the amount of positions, orders, deals, and historical orders.

CheckTradeState

Compares the current state with the saved one and calls the corresponding event handler.

```
bool CheckTradeState ()
```

Return Value

true - event has been handled, otherwise - false.

Note

It checks the number of positions, orders, deals, and historical orders by comparing with the values saved by [HistoryPoint\(\)](#) method. If trade history has changed, it calls the corresponding virtual event handler.

WaitEvent

Sets the event waiting flag.

```
void WaitEvent(  
    ENUM_TRADE_EVENTS  event      // flag  
)
```

Parameters

event

[in] Flag of waiting for an event (from ENUM_TRADE_EVENTS enumeration) to set.

Return Value

None.

Event flags

```
///--- flags of expected events  
enum ENUM_TRADE_EVENTS  
{  
    TRADE_EVENT_NO_EVENT           =0,          // no expected events  
    TRADE_EVENT_POSITION_OPEN      =0x1,        // flag of expecting the "opening of  
    TRADE_EVENT_POSITION_VOLUME_CHANGE=0x2,    // flag of expecting of the "modifica  
    TRADE_EVENT_POSITION_MODIFY     =0x4,        // flag of expecting of the "modifica  
    TRADE_EVENT_POSITION_CLOSE      =0x8,        // flag of expecting of the "closing  
    TRADE_EVENT_POSITION_STOP_TAKE  =0x10,       // flag of expecting of the "trigger  
    TRADE_EVENT_ORDER_PLACE         =0x20,       // flag of expecting of the "placing  
    TRADE_EVENT_ORDER_MODIFY        =0x40,       // flag of expecting of the "modifica  
    TRADE_EVENT_ORDER_DELETE        =0x80,       // flag of expecting of the "deletio  
    TRADE_EVENT_ORDER_TRIGGER       =0x100      // flag of expecting of the "trigger  
};
```

NoWaitEvent

Resets the event waiting flag.

```
void NoWaitEvent(  
    ENUM_TRADE_EVENTS    event    // flag  
)
```

Parameters

event

[in] Flag with events (from ENUM_TRADE_EVENTS enumeration) to reset.

Return Value

None.

Event flags

```
///--- flags of expected events  
enum ENUM_TRADE_EVENTS  
{  
    TRADE_EVENT_NO_EVENT                =0,           // no expected events  
    TRADE_EVENT_POSITION_OPEN           =0x1,         // flag of expecting the "opening of  
    TRADE_EVENT_POSITION_VOLUME_CHANGE=0x2,         // flag of expecting of the "modifica  
    TRADE_EVENT_POSITION_MODIFY         =0x4,         // flag of expecting of the "modifica  
    TRADE_EVENT_POSITION_CLOSE          =0x8,         // flag of expecting of the "closing  
    TRADE_EVENT_POSITION_STOP_TAKE      =0x10,        // flag of expecting of the "trigger  
    TRADE_EVENT_ORDER_PLACE             =0x20,        // flag of expecting of the "placing  
    TRADE_EVENT_ORDER_MODIFY            =0x40,        // flag of expecting of the "modifica  
    TRADE_EVENT_ORDER_DELETE            =0x80,        // flag of expecting of the "deletio  
    TRADE_EVENT_ORDER_TRIGGER           =0x100        // flag of expecting of the "trigger  
};
```

TradeEventPositionStopTake

Event handler of the "Position Stop Loss/Take Profit triggered" event.

```
virtual bool TradeEventPositionStopTake()
```

Return Value

The [CExpert](#) class method does nothing and always returns true.

TradeEventOrderTriggered

Event handler of the "Pending Order triggered" event.

```
virtual bool TradeEventOrderTriggered()
```

Return Value

The [CExpert](#) class method does nothing and always returns true.

TradeEventPositionOpened

Event handler of the "Position opened" event.

```
virtual bool TradeEventPositionOpened()
```

Return Value

The [CExpert](#) class method does nothing and always returns true.

TradeEventPositionVolumeChanged

Event handler of the "Position volume changed" event.

```
virtual bool TradeEventPositionVolumeChanged()
```

Return Value

The [CExpert](#) class method does nothing and always returns true.

TradeEventPositionModified

Event handler of the "Position modified" event.

```
virtual bool TradeEventPositionModified()
```

Return Value

The [CExpert](#) class method does nothing and always returns true.

TradeEventPositionClosed

Event handler of the "Position closed" event.

```
virtual bool TradeEventPositionClosed()
```

Return Value

The [CExpert](#) class method does nothing and always returns true.

TradeEventOrderPlaced

Event handler of the "Pending order placed" event.

```
virtual bool TradeEventOrderPlaced()
```

Return Value

The [CExpert](#) class method does nothing and always returns true.

TradeEventOrderModified

Event handler of the "Pending order modified" event.

```
virtual bool TradeEventOrderModified()
```

Return Value

The [CExpert](#) class method does nothing and always returns true.

TradeEventOrderDeleted

Event handler of the "Pending order deleted" event.

```
virtual bool TradeEventOrderDeleted()
```

Return Value

The [CExpert](#) class method does nothing and always returns true.

TradeEventNotIdentified

Event handler of the non-identified event.

```
virtual bool TradeEventNotIdentified()
```

Return Value

The [CExpert](#) class method does nothing and always returns true.

Note

Note that several trade events can arrive, in such cases it is difficult to identify them.

TimeframeAdd

Add a timeframe for tracking.

```
void TimeframeAdd(  
    ENUM_TIMEFRAMES    period        // timeframe  
)
```

Parameters

period

[in] Timeframe (from [ENUM_TIMEFRAMES](#) enumeration) to be tracked.

Return Value

None.

TimeframesFlags

Forms the timeframe flags.

```
int TimeframesFlags(  
    MqlDateTime&    time           // reference  
)
```

Parameters

time

[in] Reference to [MqlDateTime](#) type structure containing a new time.

Return Value

It returns the flag that indicates timeframes with a new bar.

CExpertSignal

CExpertSignal is a base class for trading signals, it does nothing (except [CheckReverseLong\(\)](#) and [CheckReverseShort\(\)](#) methods) but provides the interfaces.

How to use it:

1. Prepare an algorithm for trading signals;
2. Create your own trading signal class, inherited from CExpertSignal class;
3. Override the virtual methods in your class with your own algorithms.

You can find an examples of trading signal classes in the Expert\Signal\ folder.

Description

CExpertSignal is a base class for implementation of trading signal algorithms.

Declaration

```
class CExpertSignal : public CExpertBase
```

Title

```
#include <Expert\ExpertSignal.mqh>
```

Inheritance hierarchy

[CObject](#)

[CExpertBase](#)

CExpertSignal

Direct descendants

CSignalAC, CSignalAMA, CSignalAO, CSignalBearsPower, CSignalBullsPower, CSignalCCI, CSignalDeM, CSignalDEMA, CSignalEnvelopes, CSignalFrAMA, CSignalRSI, CSignalRVI, CSignalSAR, CSignalStoch, CSignalTEMA, CSignalTriX, CSignalWPR

Class Methods by Groups

Initialization	
virtual InitIndicators	Initializes indicators and timeseries
virtual ValidationSettings	Checks the object settings
virtual AddFilter	Adds a filter to combined signal
Access to Protected Data	
BasePrice	Sets base price level
UsedSeries	Gets the flags of timeseries used
Parameters Setting	

Weight	Sets the value of "Weight" parameter
PatternsUsage	Sets the value of "PatternsUsage" parameter
General	Sets the value of "General" parameter
Ignore	Sets the value of "Ignore" parameter
Invert	Sets the value of "Invert" parameter
ThresholdOpen	Sets the value of "ThresholdOpen" parameter
ThresholdClose	Sets the value of "ThresholdClose" parameter
PriceLevel	Sets the value of "PriceLevel" parameter
StopLevel	Sets the value of "StopLevel" parameter
TakeLevel	Sets the value of "TakeLevel" parameter
Expiration	Sets the value of "Expiration" parameter
Magic	Sets the value of "Magic" parameter
Checking Trading Conditions	
virtual CheckOpenLong	Checks conditions to open long position
virtual CheckCloseLong	Checks conditions to close long position
virtual CheckOpenShort	Checks conditions to open short position
virtual CheckCloseShort	Checks conditions to close short position
virtual CheckReverseLong	Checks conditions of long position reversal
virtual CheckReverseShort	Checks conditions of short position reversal
Trade Parameters Setting	
virtual OpenLongParams	Sets parameters for long position opening
virtual OpenShortParams	Sets parameters for short position opening
virtual CloseLongParams	Sets parameters for long position closing
virtual CloseShortParams	Sets parameters for short position closing
Checking of Order Trailing Conditions	
virtual CheckTrailingOrderLong	Checks conditions to modify parameters of Buy Pending order
virtual CheckTrailingOrderShort	Checks conditions to modify parameters of Sell Pending order
Methods to Check Formation of Market Orders	
virtual LongCondition	Gets the result of checking buy conditions

virtual ShortCondition	Gets the result of checking sell conditions
virtual Direction	Gets the "weighted" direction of price

Methods inherited from class CObject

Prev, [Prev](#), [Next](#), [Next](#), [Save](#), [Load](#), [Type](#), [Compare](#)

Methods inherited from class CExpertBase

[InitPhase](#), [TrendType](#), [UsedSeries](#), [EveryTick](#), [Open](#), [High](#), [Low](#), [Close](#), [Spread](#), [Time](#), [TickVolume](#), [RealVolume](#), [Init](#), [Symbol](#), [Period](#), [Magic](#), [SetMarginMode](#), [SetPriceSeries](#), [SetOtherSeries](#)

BasePrice

Sets base price level.

```
void BasePrice(  
    double    value        // value  
)
```

Parameters

value

[in] New value of the parameter.

Return Value

None.

UsedSeries

Gets the flags of the timeseries used.

```
int BasePrice()
```

Return Value

Flags of the used timeseries (if the symbol/timeframe corresponds to the working symbol/timeframe), otherwise 0.

Weight

Sets new value of "Weight" parameter.

```
void Weight(  
    double    value    // value  
)
```

Parameters

value

[in] "Weight" parameter.

Return Value

None.

PatternUsage

Sets new value of "PatternsUsage" parameter.

```
void PatternUsage(  
    double    value        // value  
)
```

Parameters

value

[in] New value of "PatternsUsage".

Return Value

None.

General

Sets new value of "General" parameter.

```
void General (
    int    value      // value
)
```

Parameters

value

[in] New value of "General".

Return Value

None.

Ignore

Sets new value of "Ignore" parameter.

```
void Ignore(  
    long    value    // value  
)
```

Parameters

value

[in] New value of "Ignore".

Return Value

None.

Invert

Sets new value of "Invert" parameter.

```
void Invert(  
    long    value    // value  
)
```

Parameters

value

[in] New value of "Invert".

Return Value

None.

ThresholdOpen

Sets new value of "ThresholdOpen" parameter.

```
void ThresholdOpen(  
    long    value    // value  
)
```

Parameters

value

[in] New value of "ThresholdOpen".

Return Value

None.

Note

The range of "ThresholdOpen" parameter is from 0 to 100. Used when "voting" to open position.

ThresholdClose

Sets new value of "ThresholdClose" parameter.

```
void ThresholdOpen(  
    long    value    // value  
)
```

Parameters

value

[in] New value of "ThresholdClose".

Return Value

None.

Note

The range of "ThresholdClose" parameter is from 0 to 100. Used when "voting" to close position.

PriceLevel

Sets new value of "PriceLevel" parameter.

```
void PriceLevel(  
    double    value        // value  
)
```

Parameters

value

[in] New value of "PriceLevel".

Return Value

None.

Note

The value of "PriceLevel" is defined in price level units. The numerical values of price level unit is returned by PriceLevelUnit() method. The "PriceLevel" is used to define the open price relative to the base price.

StopLevel

Sets new value of "StopLevel" parameter.

```
void StopLevel(  
    double    value        // value  
)
```

Parameters

value

[in] New value of "StopLevel".

Return Value

None.

Note

The value of "StopLevel" is defined in price level units. The numerical values of price level unit is returned by PriceLevelUnit() method. The "StopLevel" is used to define the Stop Loss price relative to the open price.

TakeLevel

Sets new value of "TakeLevel" parameter.

```
void TakeLevel(  
    double    value        // value  
)
```

Parameters

value

[in] New value of "TakeLevel".

Return Value

None.

Note

The value of "TakeLevel" is defined in price level units. The numerical values of price level unit is returned by PriceLevelUnit() method. The "TakeLevel" is used to define the Take Profit price relative to the open price.

Expiration

Sets the value of "Expiration" parameter.

```
void Expiration(  
    int    value        // value  
)
```

Parameters

value

[in] New value of "Expiration".

Return Value

None.

Note

The value of "Expiration" parameter is defined in bars. It is used as Expiration time for Pending Orders (when trading using pending orders).

Magic

Sets the value of "Magic" parameter.

```
void Magic(  
    int    value    // value  
)
```

Parameters

value

[in] New value of "Magic" (Expert Advisor ID).

Return Value

None.

ValidationSettings

Checks the object settings.

```
virtual bool ValidationSettings()
```

Return Value

true - object settings are correct, otherwise - false.

InitIndicators

Initializes all necessary indicators and timeseries.

```
virtual bool InitIndicators(  
    CIndicators* indicators // pointer  
)
```

Parameters

indicators

[in] Pointer to collection of indicators and timeseries.

Return Value

true - successful completion, otherwise - false.

Note

The necessary timeseries are initialized only if the object uses the symbol or timeframe different from the one defined at initialization.

AddFilter

Adds a filter to the composite signal.

```
virtual bool InitIndicators(  
    CExpertSignal* filter    // pointer  
)
```

Parameters

indicators

[in] Pointer to filter object.

Return Value

true - successful, otherwise - false.

CheckOpenLong

Checks conditions to open a long position.

```
virtual bool CheckOpenLong(  
    double& price,           // price  
    double& sl,              // Stop Loss  
    double& tp,              // Take Profit  
    datetime& expiration    // expiration  
)
```

Parameters

price

[in][out] Variable for open price, passed by reference.

sl

[in][out] Variable for Stop Loss price, passed by reference.

tp

[in][out] Variable for Take Profit price, passed by reference.

expiration

[in][out] Variable for expiration time, passed by reference (if necessary).

Return Value

true - condition is satisfied, otherwise - false.

CheckOpenShort

Checks conditions to open a short position.

```
virtual bool CheckOpenShort(  
    double& price,           // price  
    double& sl,              // Stop Loss  
    double& tp,              // Take Profit  
    datetime& expiration    // expiration  
)
```

Parameters

price

[in][out] Variable for open price, passed by reference.

sl

[in][out] Variable for Stop Loss price, passed by reference.

tp

[in][out] Variable for Take Profit price, passed by reference.

expiration

[in][out] Variable for expiration time, passed by reference (if necessary).

Return Value

true - condition is satisfied, otherwise - false.

OpenLongParams

Sets parameters to open a long position.

```
virtual bool OpenLongParams(  
    double& price,           // price  
    double& sl,             // Stop Loss  
    double& tp,             // Take Profit  
    datetime& expiration    // expiration  
)
```

Parameters

price

[in][out] Variable for open price, passed by reference.

sl

[in][out] Variable for Stop Loss price, passed by reference.

tp

[in][out] Variable for Take Profit price, passed by reference.

expiration

[in][out] Variable for expiration time, passed by reference (if necessary).

Return Value

true - successful, otherwise - false.

OpenShortParams

Sets parameters to open a short position.

```
virtual bool OpenShortParams(  
    double& price,           // price  
    double& sl,              // Stop Loss  
    double& tp,              // Take Profit  
    datetime& expiration    // expiration  
)
```

Parameters

price

[in][out] Variable for price, passed by reference.

sl

[in][out] Variable for Stop Loss price, passed by reference.

tp

[in][out] Variable for Take Profit price, passed by reference.

expiration

[in][out] Variable for expiration time, passed by reference (if necessary).

Return Value

true - successful, otherwise - false.

CheckCloseLong

Checks conditions to close a long position.

```
virtual bool CheckCloseLong(  
    double& price    // price  
)
```

Parameters

price

[in][out] Variable for close price, passed by reference.

Return Value

true - condition is satisfied, otherwise - false.

CheckCloseShort

Checks conditions to close a short position.

```
virtual bool CheckCloseShort(  
    double& price    // price  
)
```

Parameters

price

[in][out] Variable for close price, passed by reference.

Return Value

true - condition is satisfied, otherwise - false.

CloseLongParams

Sets parameters to close a long position.

```
virtual bool CloseLongParams(  
    double& price // price  
)
```

Parameters

price

[in][out] Variable for close price, passed by reference.

Return Value

true - successful, otherwise - false.

CloseShortParams

Sets parameters to close a short position.

```
virtual bool CloseShortParams (  
    double& price // price  
)
```

Parameters

price

[in][out] Variable for close price, passed by reference.

Return Value

true - successful, otherwise - false.

CheckReverseLong

Checks conditions of a long position reversal.

```
virtual bool CheckReverseLong(  
    double& price,           // price  
    double& sl,              // Stop Loss  
    double& tp,              // Take Profit  
    datetime& expiration    // expiration  
)
```

Parameters

price

[in][out] Variable for price, passed by reference.

sl

[in][out] Variable for Stop Loss price, passed by reference.

tp

[in][out] Variable for Take Profit price, passed by reference.

expiration

[in][out] Variable for expiration time, passed by reference (if necessary).

Return Value

true - condition is satisfied, otherwise - false.

CheckReverseShort

Checks conditions of a short position reversal.

```
virtual bool CheckReverseShort(  
    double& price,           // price  
    double& sl,              // Stop Loss  
    double& tp,              // Take Profit  
    datetime& expiration    // expiration  
)
```

Parameters

price

[in][out] Variable for reversal price, passed by reference.

sl

[in][out] Variable for Stop Loss price, passed by reference.

tp

[in][out] Variable for Take Profit price, passed by reference.

expiration

[in][out] Variable for expiration time, passed by reference (if necessary).

Return Value

true - condition is satisfied, otherwise - false.

CheckTrailingOrderLong

Checks conditions to modify parameters of Buy Pending order.

```
virtual bool CheckTrailingOrderLong(  
    COrderInfo*   order,          // order  
    double&       price           // price  
)
```

Parameters

order

[in] Pointer to [COrderInfo](#) class object.

price

[in][out] Variable for Stop Loss price.

Return Value

true - condition is satisfied, otherwise - false.

CheckTrailingOrderShort

Checks conditions to modify parameters of Sell Pending order.

```
virtual bool CheckTrailingOrderShort(  
    COrderInfo*    order,          // order  
    double&        price           // price  
)
```

Parameters

order

[in] Pointer to [COrderInfo](#) class object.

price

[in][out] Variable for Stop Loss price.

Return Value

true - condition is satisfied, otherwise - false.

LongCondition

Checks conditions to open a long position.

```
virtual int LongCondition()
```

Return Value

If the conditions are satisfied, it returns the value from 1 to 100 (depending on "strength" of a signal). If there is no signal to open a long position, it returns 0.

Note

The base class has no implementation of checking conditions to open a long position and always returns 0.

ShortCondition

Checks conditions to open a short position.

```
virtual int ShortCondition()
```

Return Value

If the conditions are satisfied, it returns the value from 1 to 100 (depending on "strength" of a signal). If there isn't a signal to open short position, it returns 0.

Note

The base class has no implementation of checking conditions to open a short position and always returns 0.

Direction

Returns the value of "weighted" price direction.

```
virtual double Direction()
```

Return Value

It returns the value >0 when upward direction is most probable and <0 in case of a downward direction. The absolute value depends on the "strength" of a signal.

Note

If the built-in filters are used, their results are considered when defining the general direction.

CExpertTrailing

CExpertTrailing is a base class for trailing algorithms, it does nothing but provides the interfaces.

How to use it:

1. Prepare an algorithm for trailing;
2. Create your own trailing class inherited from CExpertTrailing class;
3. Override the virtual methods in your class with your own algorithms.

You can find an examples of trailing classes in the Expert\Trailing\ folder.

Description

CExpertTrailing is a base class for implementation of trailing stop algorithms.

Declaration

```
class CExpertTrailing : public CExpertBase
```

Title

```
#include <Expert\ExpertTrailing.mqh>
```

Inheritance hierarchy

[CObject](#)

CheckTrailingStopLong

Checks conditions to modify parameters of a long position.

```
virtual bool CheckTrailingStopLong(  
    CPositionInfo* position,    // pointer  
    double& sl,                // Stop Loss  
    double& tp                 // Take Profit  
)
```

Parameters

position

[in] Pointer to [CPositionInfo](#) class object.

sl

[in][out] Variable for Stop Loss price, passed by reference.

tp

[in][out] Variable for Take Profit price, passed by reference.

Return Value

true - condition is satisfied, otherwise - false.

Note

Base class method always returns false.

CheckTrailingStopShort

Checks conditions to modify parameters of a short position.

```
virtual bool CheckTrailingStopShort (
    CPositionInfo* position,    // pointer
    double& sl,                // Stop Loss
    double& tp                 // Take Profit
)
```

Parameters

position

[in] Pointer to [CPositionInfo](#) class object.

sl

[in][out] Variable for Stop Loss price, passed by reference.

tp

[in][out] Variable for Take Profit price, passed by reference.

Return Value

true - condition is satisfied, otherwise - false.

Note

Base class method always returns false.

CExpertMoney

CExpertMoney is a base class for money and risk management algorithms.

Description

CExpertMoney is a base class for implementation of money and risk management classes.

Declaration

```
class CExpertMoney : public CObject
```

Title

```
#include <Expert\ExpertMoney.mqh>
```

Inheritance hierarchy

Percent

Sets the value of "Risk percent" parameter.

```
void Percent(  
    double percent    // risk percent  
)
```

Parameters

percent

[in] Risk percent.

Return Value

None.

ValidationSettings

Checks the settings.

```
virtual bool ValidationSettings()
```

Return Value

true - successful, otherwise - false.

Note

Base class method always returns true.

CheckOpenLong

Gets the volume for a long position.

```
virtual double CheckOpenLong(  
    double price,      // price  
    double sl          // Stop Loss  
)
```

Parameters

price

[in] Opening price of a long position.

sl

[in] Stop Loss price of a long position.

Return Value

Trade volume for a long position.

CheckOpenShort

Gets the volume for a short position.

```
virtual double CheckOpenShort(  
    double price,      // price  
    double sl          // Stop Loss  
)
```

Parameters

price

[in] Opening price for a short position.

sl

[in] Stop Loss price of a short position.

Return Value

Trade volume for a short position.

CheckReverse

Gets the volume for reverse of the position.

```
virtual double CheckReverse(  
    CPositionInfo* position,    // pointer  
    double sl                  // Stop Loss  
)
```

Parameters

position

[in] Pointer to [CPositionInfo](#) class object.

sl

[in] Stop Loss price.

Return Value

Volume for reverse of the position.

CheckClose

Checks conditions to close the opened position.

```
virtual double CheckClose()
```

Return Value

true - condition is satisfied, otherwise - false.

Modules of Trade Signals

The standard delivery of the client terminal includes a set of ready-made modules of trade signals for "MQL5 Wizard". When creating an Expert Advisor in MQL5 Wizard, you can use any combination of the modules of trade signals (up to 64). The final decision on a trade operation is made on the basis of complex analysis of signals obtained from all included modules. The detailed description of the mechanism of making trade decisions is given [below](#).

The standard delivery includes the following modules of signals:

- [Signals of the Indicator Accelerator Oscillator](#)
- [Signals of the Indicator Adaptive Moving Average](#)
- [Signals of the Indicator Awesome Oscillator](#)
- [Signals of the Oscillator Bears Power](#)
- [Signals of the Oscillator Bulls Power](#)
- [Signals of the Oscillator Commodity Channel Index](#)
- [Signals of the Oscillator DeMarker](#)
- [Signals of the Indicator Double Exponential Moving Average](#)
- [Signals of the Indicator Envelopes](#)
- [Signals of the Indicator Fractal Adaptive Moving Average](#)
- [Signals of the Intraday Time Filter](#)
- [Signals of the Oscillator MACD](#)
- [Signals of the Indicator Moving Average](#)
- [Signals of the Indicator Parabolic SAR](#)
- [Signals of the Oscillator Relative Strength Index](#)
- [Signals of the Oscillator Relative Vigor Index](#)
- [Signals of the Oscillator Stochastic](#)
- [Signals of the Oscillator Triple Exponential Average](#)
- [Signals of the Indicator Triple Exponential Moving Average](#)
- [Signals of the Oscillator Williams Percent Range](#)

The Mechanism of Making Trade Decisions on the Basis of Signal Modules

The mechanism of making trade decisions can be represented as the following list of basic principles:

- Each of the modules of signals has its set of market modules (certain combination of prices and values of an indicator).
- Each market model has a significance that may vary with the range of 1 to 100. The higher is the significance, the stronger the model is.
- Each of the models generates a forecast of direction of the price movement.
- A forecast of a module is the result of search for embedded models, and it is outputted as a number within the range of -100 to 100. The sign determines the direction of forecast movement (negative

sign means the price will fall, positive sign means the price will rise). The absolute value corresponds to the strength of the best found model.

- The forecast of each module is sent to the final "voting" with a weight coefficient of 0 to 1 specified in its settings ("Weight").
- The result of voting is a number within the range of -100 to 100, where the sign determines direction of the forecast movement, and the absolute value characterizes the strength of the signal. It is calculated as the Arithmetic mean of weighted forecasts of all the modules of signals. The absolute value is used by an Expert Advisor to make trade decisions.

Each generated Expert Advisor has two adjustable settings – threshold levels of opening and closing a position (ThresholdOpen and ThresholdClose) that can be equal to a value in the range of 0 to 100. If the strength of final signal exceeds a threshold level, a trade operation that corresponds to the sign of the signal is performed.

Examples

Consider an Expert Advisor with the following threshold levels: ThresholdOpen=20 and ThresholdClose=90. Two modules of signals participate in making decisions on trade operations: the [MA](#) module with weight 0.4 and the [Stochastic](#) module with weight 0.8. Let's analyze two variants of obtained trade signals:

Variant 1

The price crossed the rising MA upwards. This case corresponds to one of the market models implemented in the [MA module](#). This model implies a rise of price. Its significance is equal to 100. At the same time, the Stochastic oscillator turned down and formed a divergence with price. This case corresponds to one of the models implemented in the [Stochastic module](#). This model implies a fall of price. The weight of this model is 80.

Let's calculate the result of final "voting". The rate obtained from the MA module is calculated as $0.4 * 100 = 40$. The value from the Stochastic module is calculated as $0.8 * (-80) = -64$. The final value is calculated as the Arithmetic mean of these two rates: $(40 - 64)/2 = -12$. The result of voting is the signal for selling with relative strength equal to 12. The threshold level that is equal to 20 is not reached. Thus a trade operation is not performed.

Variant 2

The price crossed the rising MA downwards. This case corresponds to one of the models implemented in the [MA module](#). This model implies a rise of price. Its significance is equal to 10. At the same time, the Stochastic oscillator turned down and formed a divergence with price. This case corresponds to one of the models implemented in the [Stochastic module](#). This model implies a fall of price. The weight of this model is 80.

Let's calculate the result of final "voting". The rate obtained from the MA module is calculated as $0.4 * 10 = 4$. The value from the Stochastic module is calculated as $0.8 * (-80) = -64$. The final value is calculated as the Arithmetic mean of these two rates: $(4 - 64)/2 = -30$. The result of voting is the signal for selling with relative strength equal to 30. The threshold level that is equal to 20 is reached. Thus the result is the signal for opening a short position.

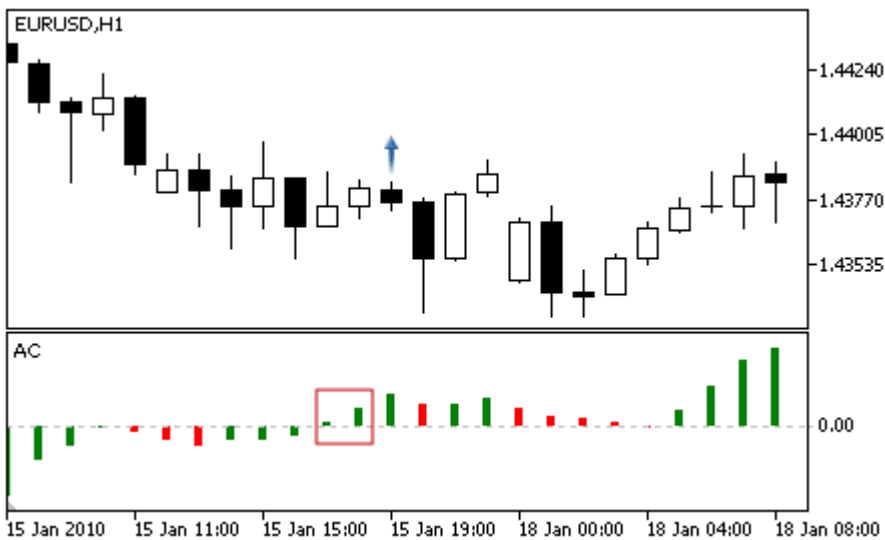

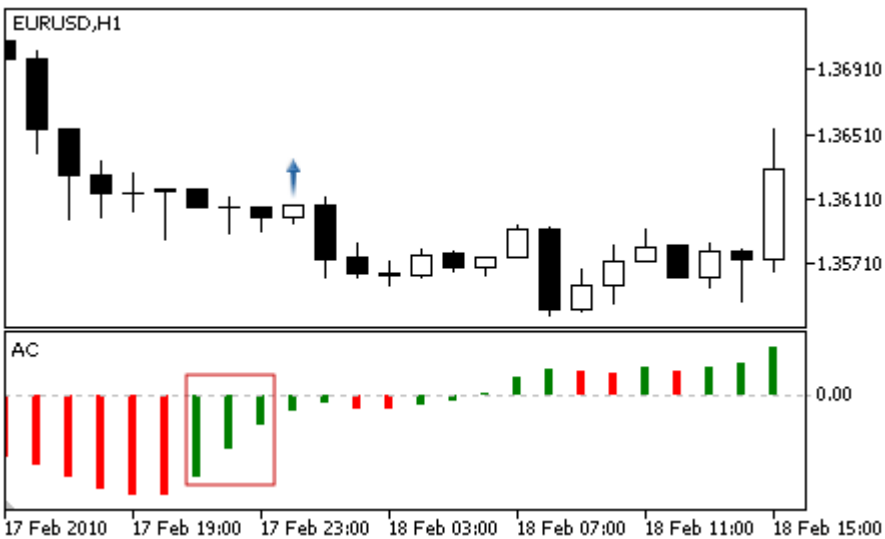

- a) Divergence of the price and the Stochastic oscillator (variants 1 and 2).
- b) The price crossed the MA indicator upwards (variant 1).
- c) The price crossed the MA indicator downwards (variant 2).

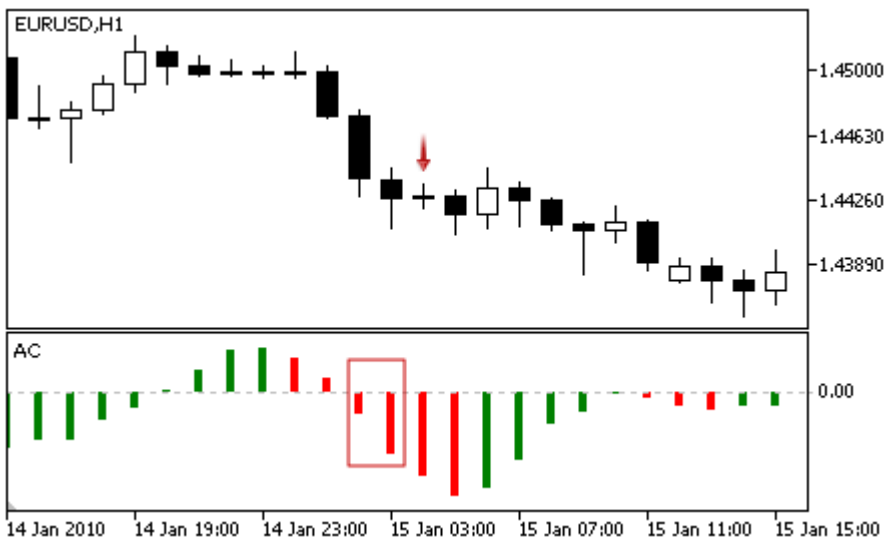

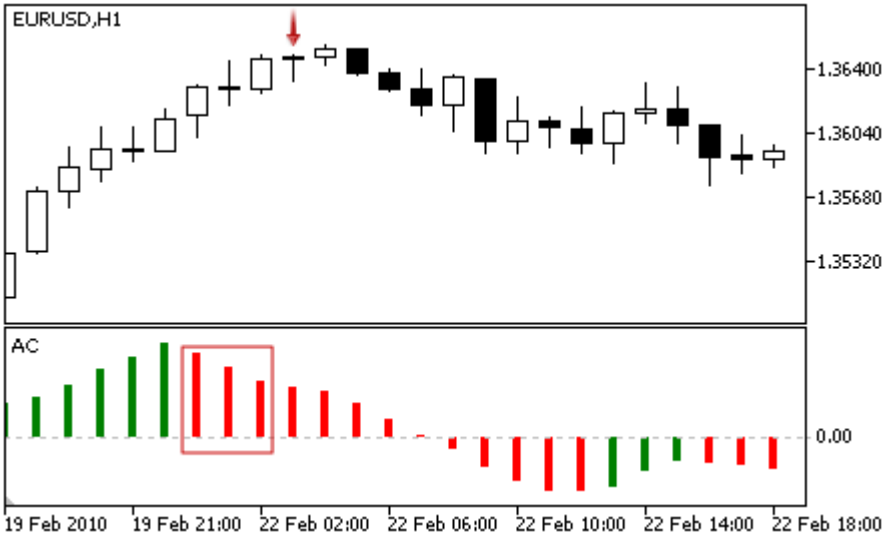

Signals of the Indicator Accelerator Oscillator

This module is based on the market models of the indicator [Accelerator Oscillator](#). The mechanism of making trade decisions based on signals obtained from the modules is described in a [separate section](#).

Conditions of Generation of Signals

Below you can find the description of conditions when the module passes a signal to an Expert Advisor.

Signal Type	Description of Conditions
For buying	<ul style="list-style-type: none"> The indicator value is above 0 and it rises at the analyzed and at the previous bars.  <ul style="list-style-type: none"> The indicator value is below 0 and it rises at the analyzed and at the previous bars. 
For selling	<ul style="list-style-type: none"> The indicator value is below 0 and it falls at the analyzed and at the previous bars.

Signal Type	Description of Conditions
	 <ul style="list-style-type: none"> The indicator value is above 0 and it falls at the analyzed and at the two previous bars. 
No objections to buying	The indicator value grows at the analyzed bar.
No objections to selling	The indicator value falls at the analyzed bar.

Note

Depending on the mode of operation of an Expert Advisor ("Every tick" or "Open prices only"), an analyzed bar is either the current bar (with index 0), or the last formed bar (with index 1).

Adjustable Parameters

This module has the following adjustable parameters:

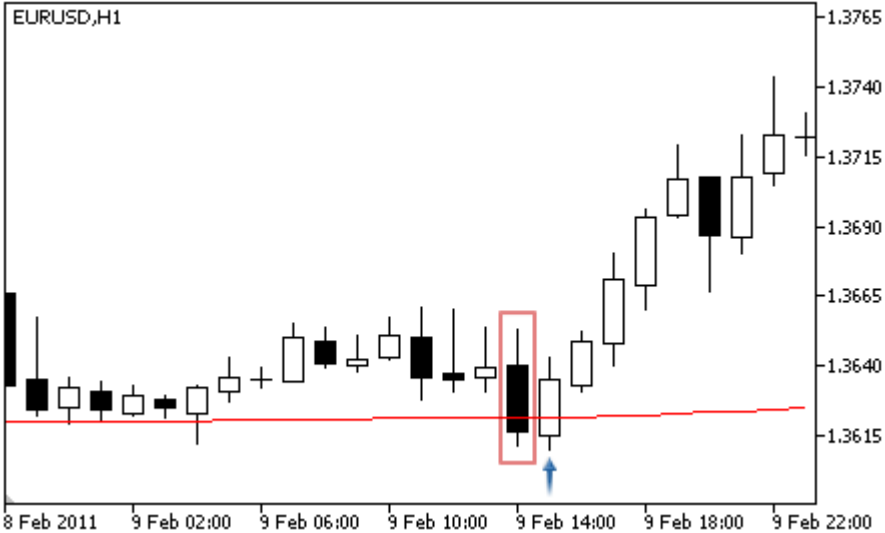

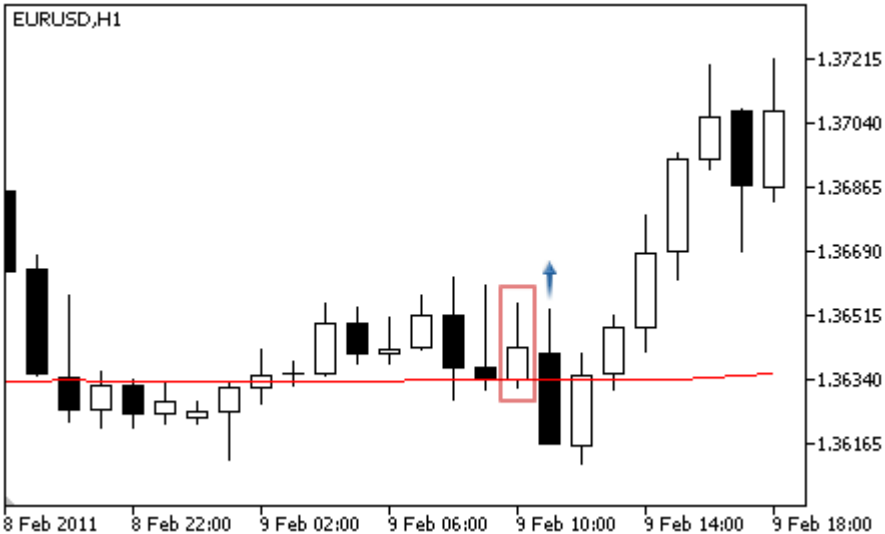

Parameter	Description
Weight	Weight of signal of the module in the interval 0 to 1.

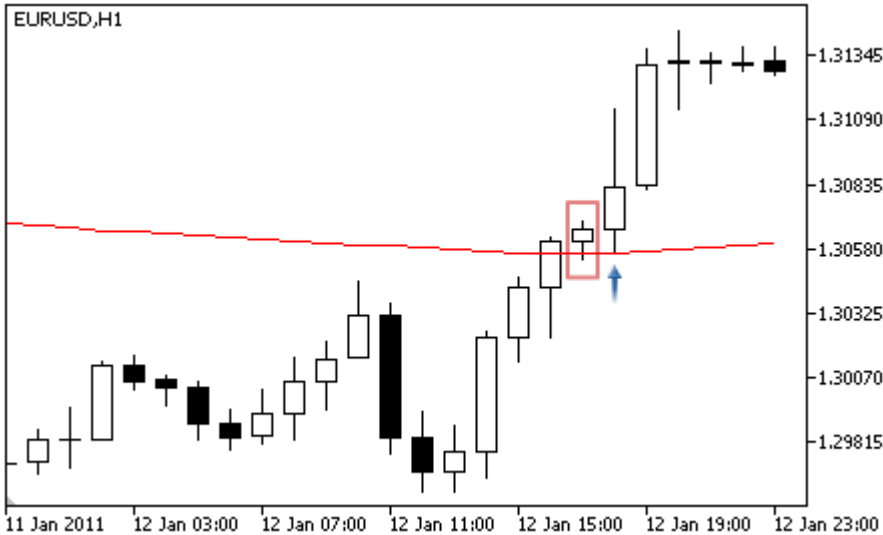

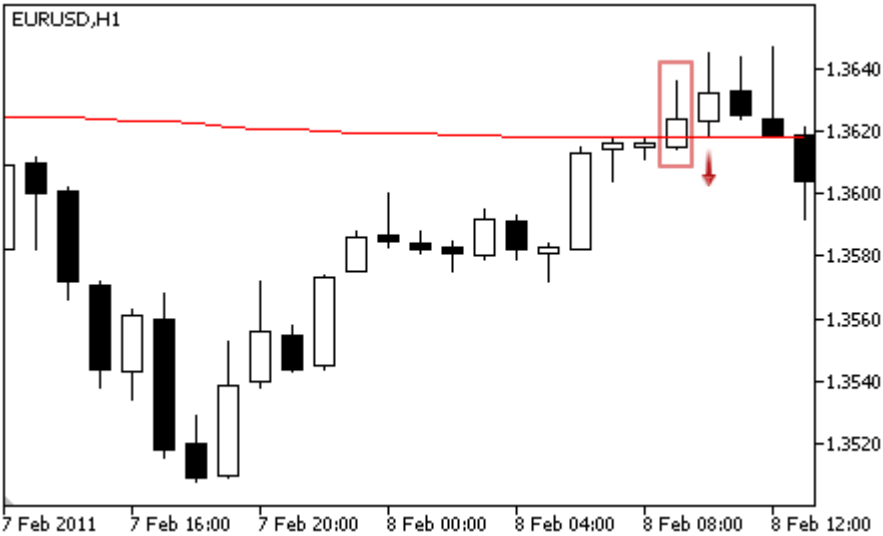

Signals of the Indicator Adaptive Moving Average

This module is based on the market models of the indicator [Adaptive Moving Average](#). The mechanism of making trade decisions based on signals obtained from the modules is described in a [separate section](#).

Conditions of Generation of Signals

Below you can find the description of conditions when the module passes a signal to an Expert Advisor.

Signal Type	Description of Conditions
For buying	<ul style="list-style-type: none"> Failed breakout. The price has crossed the indicator downwards (the Open price of the analyzed bar is above the indicator and the Close price is below the indicator) but the indicator rises (weak indicator line roll-back signal).  Moving Average crossover. The price has crossed the indicator upwards (the Open price of the analyzed bar is below the indicator and the Close price is above the indicator) and the indicator rises (strong signal). 

Signal Type	Description of Conditions
	<ul style="list-style-type: none"> • True breakout. The lower shadow of the bar has crossed the indicator (the Open and Close prices of the analyzed bar is above the indicator, and the Low price is below the indicator) and the indicator rises (indicator line roll-back signal). 
For selling	<ul style="list-style-type: none"> • Failed breakout. The price has crossed the indicator upwards (the Open price of the analyzed bar is below the indicator and the Close price is above the indicator) but the indicator falls (weak indicator line roll-back signal).  <ul style="list-style-type: none"> • Moving Average crossover. The price has crossed the indicator downwards (the Open price of the analyzed bar is above the indicator and the Close price is below the indicator) and the indicator falls (strong signal).

Signal Type	Description of Conditions
	 <ul style="list-style-type: none"> • True breakout. The upper shadow of the bar has crossed the indicator (the Open and Close prices of the analyzed bar are below the indicator, and the High price is above the indicator) and the indicator falls (indicator line roll-back signal). 
No objections to buying	The price is above the indicator.
No objections to selling	The price is below the indicator.

Note

Depending on the mode of operation of an Expert Advisor ("Every tick" or "Open prices only"), an analyzed bar is either the current bar (with index 0), or the last formed bar (with index 1).

Adjustable Parameters

This module has the following adjustable parameters:

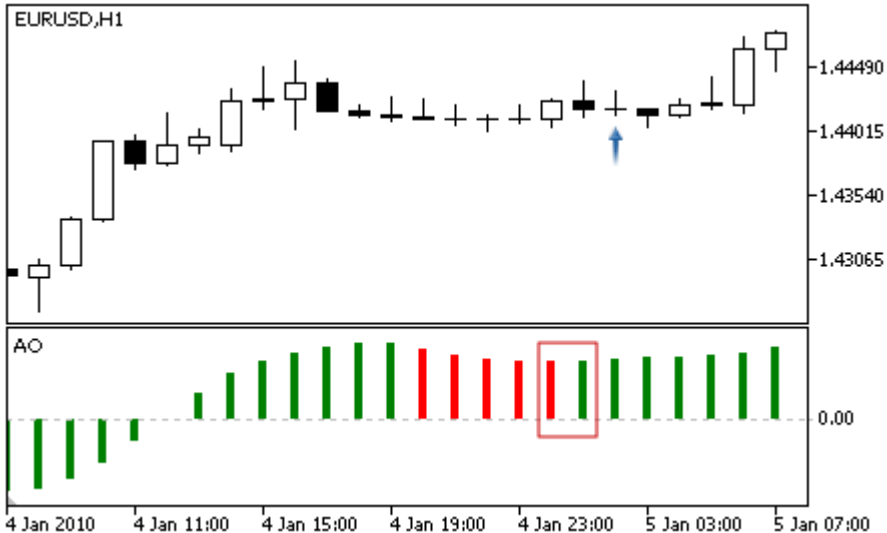

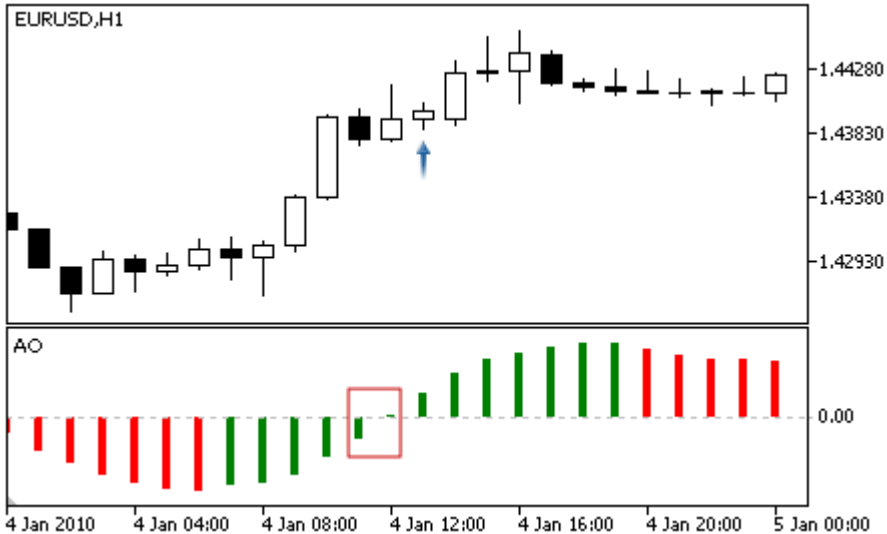

Parameter	Description
Weight	Weight of signal of the module in the interval 0 to 1.
PeriodMA	Period of averaging of the indicator.
Shift	Shift of the indicator along the time axis (in bars).
Method	Method of averaging .
Applied	A price series used for calculation of the indicator.

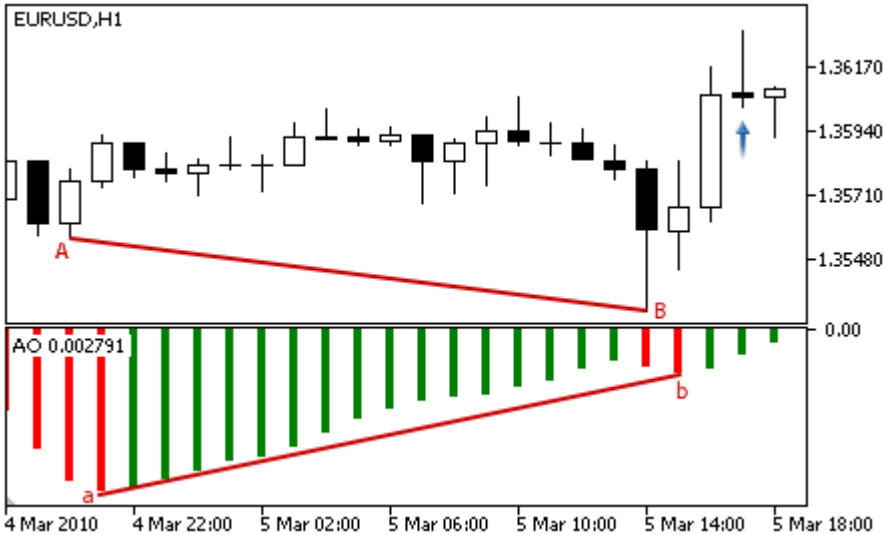

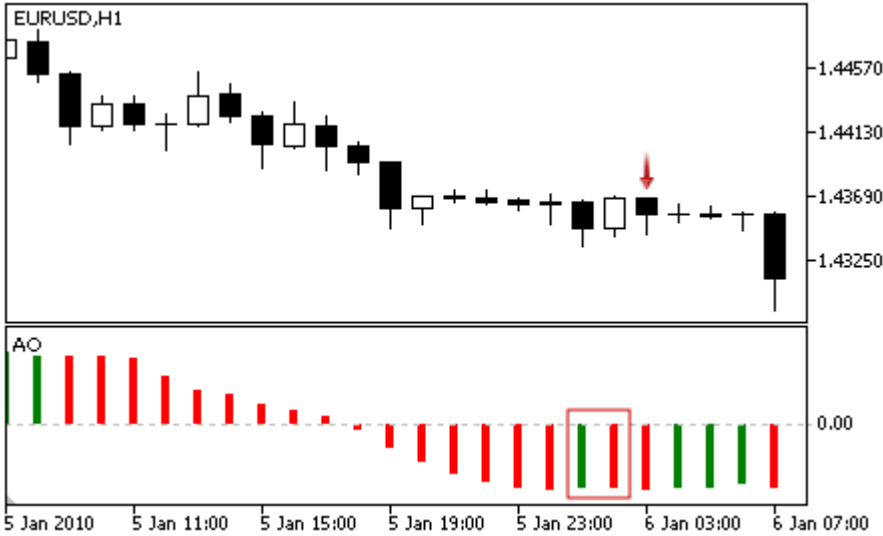

Signals of the Indicator Awesome Oscillator

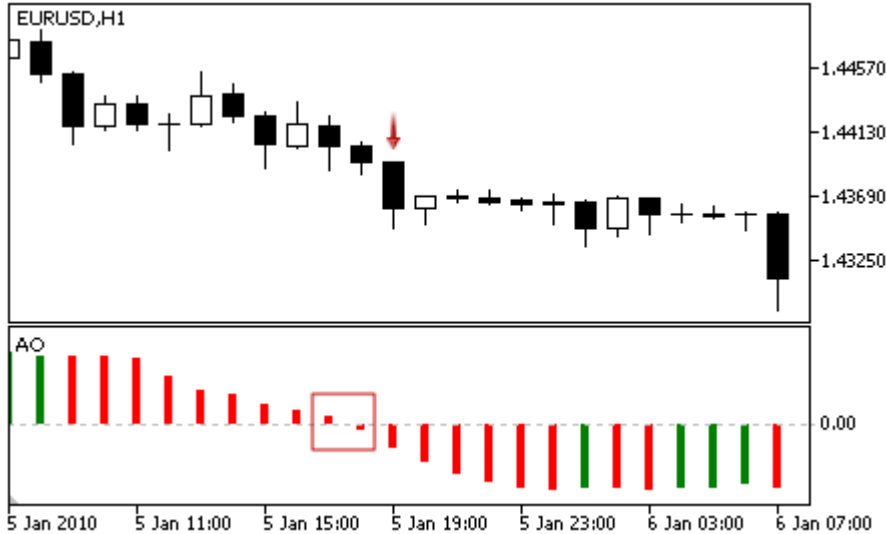

This module of signals is based on the market models of the indicator [Awesome Oscillator](#). The mechanism of making trade decisions based on signals obtained from the modules is described in a [separate section](#).

Conditions of Generation of Signals

Below you can find the description of conditions when the module passes a signal to an Expert Advisor.

Signal Type	Description of Conditions
For buying	<ul style="list-style-type: none"> Saucer – value of the indicator at the analyzed bar rises, and it fell at the previous bars; at that, both values are above 0.  Crossing the zero line – value of the indicator is above 0 at the analyzed bar, and it is below 0 at the previous bar. 

Signal Type	Description of Conditions
	<ul style="list-style-type: none"> • Divergence — the first analyzed bottom of the indicator is shallower than the previous one, and the corresponding price bottom is deeper than the previous one. In addition, the indicator must not rise above the zero level. 
For selling	<ul style="list-style-type: none"> • Saucer — value of the indicator at the analyzed bar falls, and it rose at the previous bars; at that, both values are below 0.  <ul style="list-style-type: none"> • Crossing the zero line — value of the indicator is below 0 at the analyzed bar, and it is above 0 at the previous bar.

Signal Type	Description of Conditions
	 <ul style="list-style-type: none"> • Divergence – the first analyzed peak of the indicator is lower than the previous one, and the corresponding price peak is higher than the previous one. In addition, the indicator must not fall below the zero level. 
No objections to buying	The indicator value grows at the analyzed bar.
No objections to selling	The indicator value falls at the analyzed bar.

Note

Depending on the mode of operation of an Expert Advisor ("Every tick" or "Open prices only") an analyzed bar is either the current bar (with index 0), or the last formed bar (with index 1).

Adjustable Parameters

This module has the following adjustable parameters:

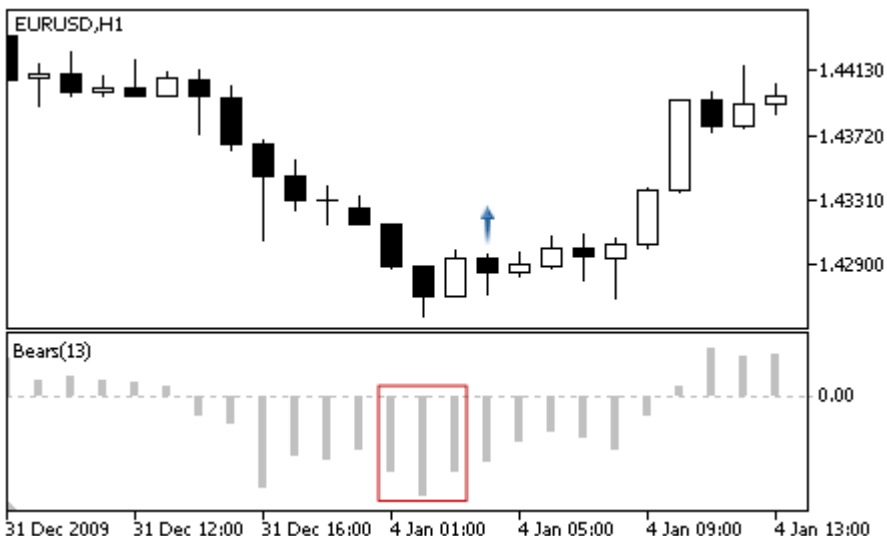

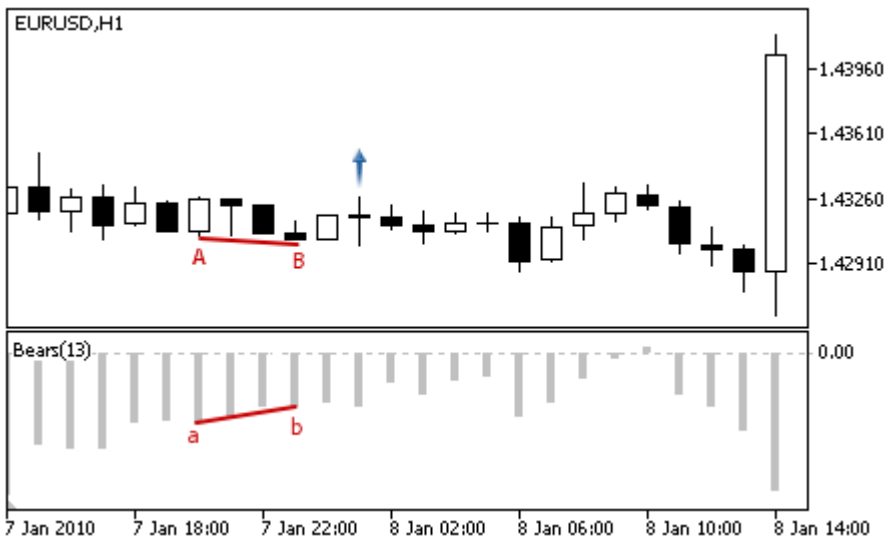

Parameter	Description
Weight	Weight of signal of the module in the interval 0 to 1.

Signals of the Oscillator Bears Power

This module of signals is based on the market models of the oscillator [Bears Power](#). The mechanism of making trade decisions based on signals obtained from the modules is described in a [separate section](#).

Conditions of Generation of Signals

Below you can find the description of conditions when the module passes a signal to an Expert Advisor.

Signal Type	Description of Conditions
For buying	<ul style="list-style-type: none"> Reverse — the oscillator turned upwards and its value at the analyzed bar is below 0.  Divergence — the first analyzed bottom of the oscillator is higher than the previous one, and the corresponding price bottom is lower than the previous one. In addition, the oscillator must not rise above the zero level. 
For selling	No signals for selling.

Signal Type	Description of Conditions
No objections to buying	Value of the oscillator is less than 0.
No objections to selling	No signals.

Note

Depending on the mode of operation of an Expert Advisor ("Every tick" or "Open prices only") an analyzed bar is either the current bar (with index 0), or the last formed bar (with index 1).

Adjustable Parameters

This module has the following adjustable parameters:

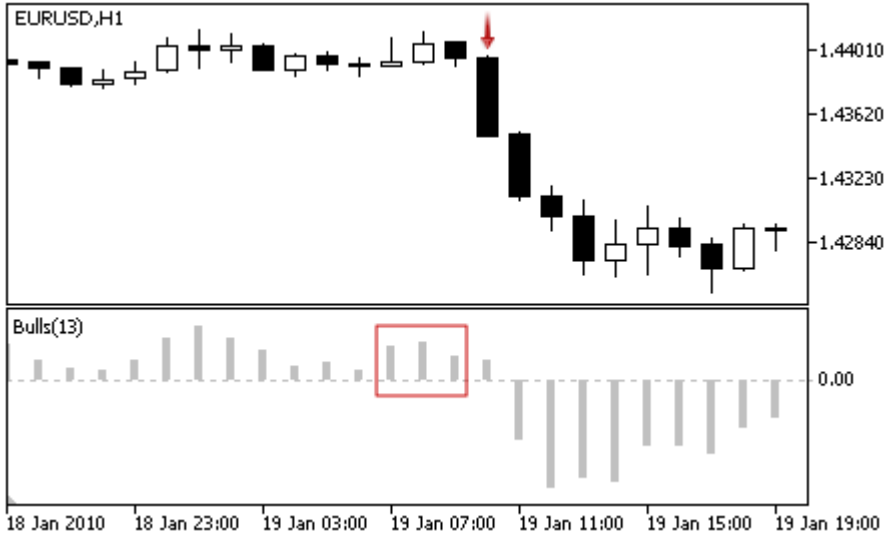

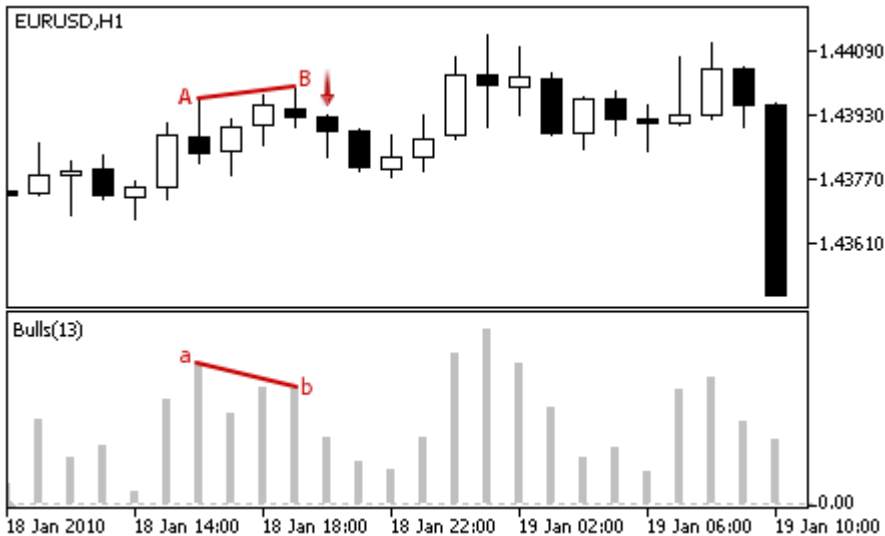

Parameter	Description
Weight	Weight of signal of the module in the interval 0 to 1.
PeriodBears	Period of calculation of the oscillator.

Signals of the Oscillator Bulls Power

This module of signals is based on the market models of the oscillator [Bulls Power](#). The mechanism of making trade decisions based on signals obtained from the modules is described in a [separate section](#).

Conditions of Generation of Signals

Below you can find the description of conditions when the module passes a signal to an Expert Advisor.

Signal Type	Description of Conditions
For buying	No signals for buying.
For selling	<ul style="list-style-type: none"> Reverse – the oscillator turned downwards and its value at the analyzed bar is above 0.  Divergence – the first analyzed peak of the oscillator is lower than the previous one, and the corresponding price peak is higher than the previous peak. In addition, the oscillator must not fall below the zero level. 

Signal Type	Description of Conditions
No objections to buying	No signals.
No objections to selling	Value of the oscillator is greater than 0.

Note

Depending on the mode of operation of an Expert Advisor ("Every tick" or "Open prices only") an analyzed bar is either the current bar (with index 0), or the last formed bar (with index 1).

Adjustable Parameters

This module has the following adjustable parameters:

Parameter	Description
Weight	Weight of signal of the module in the interval 0 to 1.
PeriodBulls	Period of calculation of the oscillator.

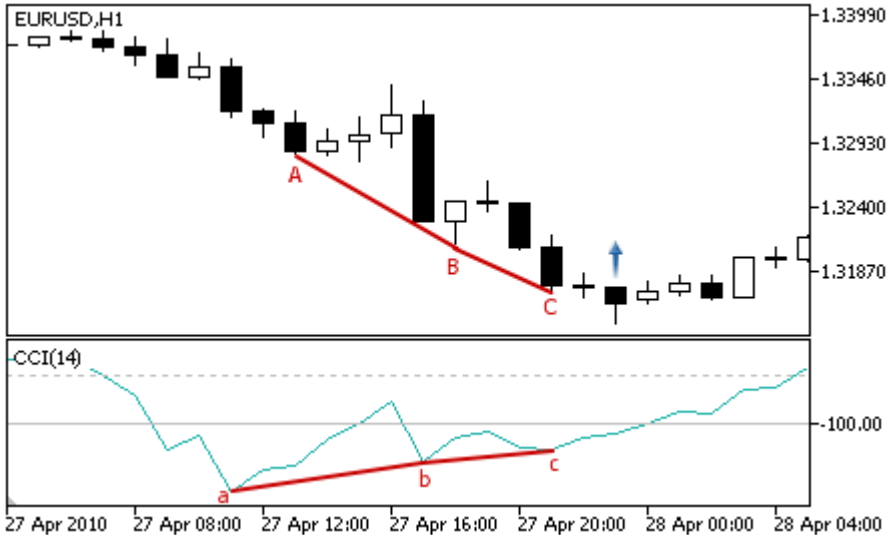

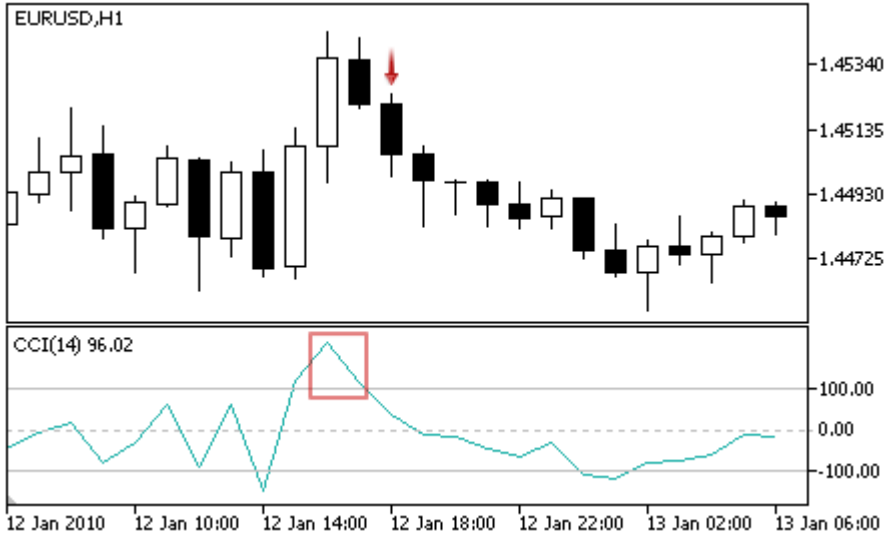

Signals of the Oscillator Commodity Channel Index

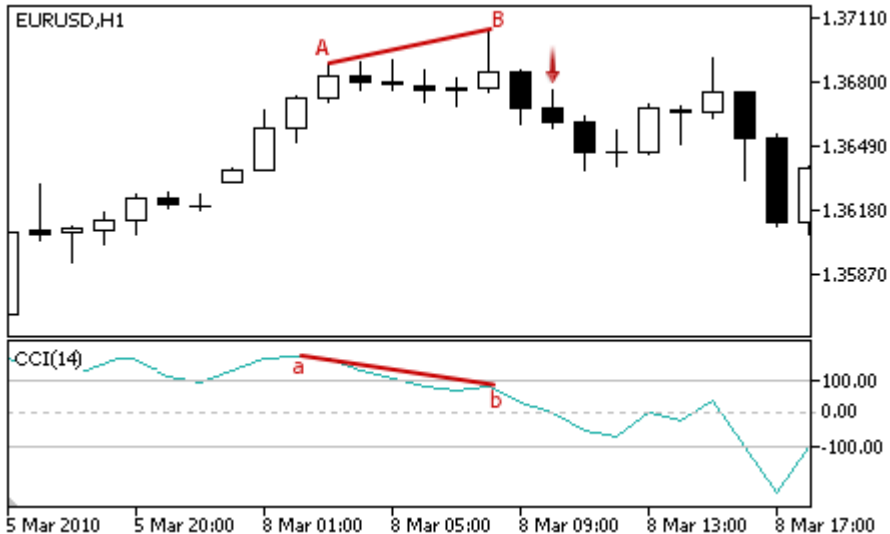

This module of signals is based on the market models of the oscillator [Commodity Channel Index](#). The mechanism of making trade decisions based on signals obtained from the modules is described in a [separate section](#).

Conditions of Generation of Signals

Below you can find the description of conditions when the module passes a signal to an Expert Advisor.

Signal Type	Description of Conditions
For buying	<ul style="list-style-type: none"> Reverse behind the oversold level – the oscillator turned upwards and its value at the analyzed bar is behind the level of oversold level (default value is -100).  Divergence – the first analyzed bottom of the oscillator is higher than the previous one, and the corresponding price bottom is lower than the previous one. 

Signal Type	Description of Conditions
	<ul style="list-style-type: none"> • Double divergence – the oscillator formed three consequent bottoms, each of them is higher than the previous one; and the price formed three corresponding bottoms, and each of them is lower than the previous one. 
For selling	<ul style="list-style-type: none"> • Reverse behind the overbought level – the oscillator turned downwards and its value at the analyzed bar is behind the overbought level (default value is 100).  <ul style="list-style-type: none"> • Divergence – the first analyzed peak of the oscillator is lower than the previous one, and the corresponding price peak is higher than the previous peak.

Signal Type	Description of Conditions
	 <ul style="list-style-type: none"> • Double divergence – the oscillator formed three consequent peaks, each of them is lower than the previous one; and the price formed three corresponding peaks, each of them is higher than the previous one. 
No objections to buying	Value of the oscillator grows at the analyzed bar.
No objections to selling	Value of the oscillator falls at the analyzed bar.

Note

Depending on the mode of operation of an Expert Advisor ("Every tick" or "Open prices only") an analyzed bar is either the current bar (with index 0), or the last formed bar (with index 1).

Adjustable Parameters

This module has the following adjustable parameters:

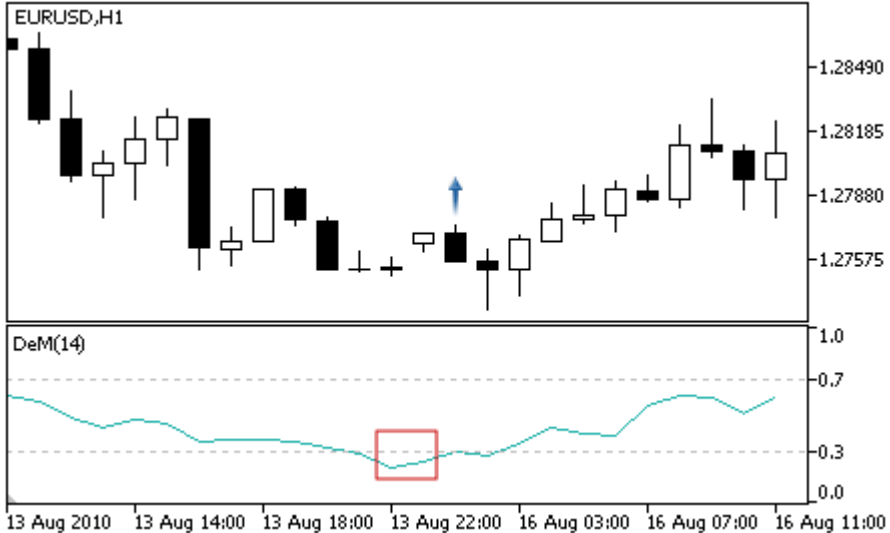

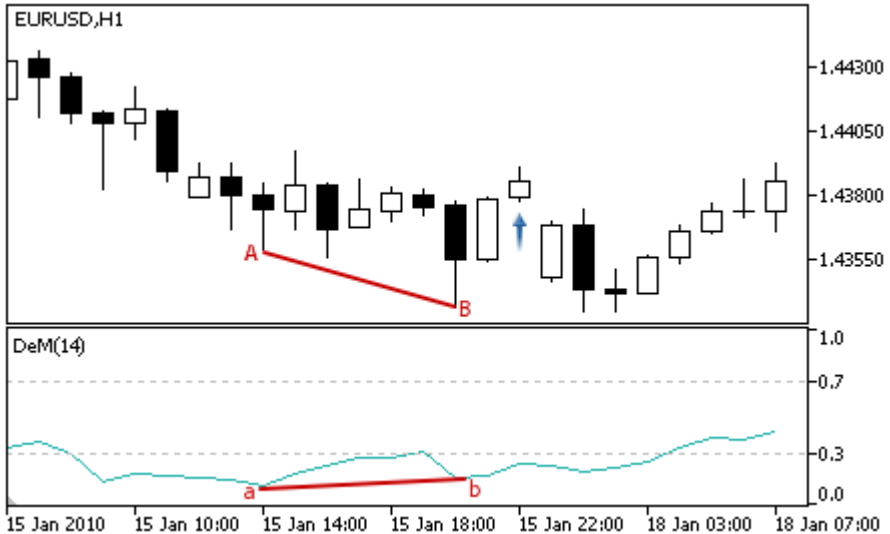

Parameter	Description
Weight	Weight of signal of the module in the interval 0 to 1.
PeriodCCI	Period of calculation of the oscillator.
Applied	A price series used for calculation of the oscillator.

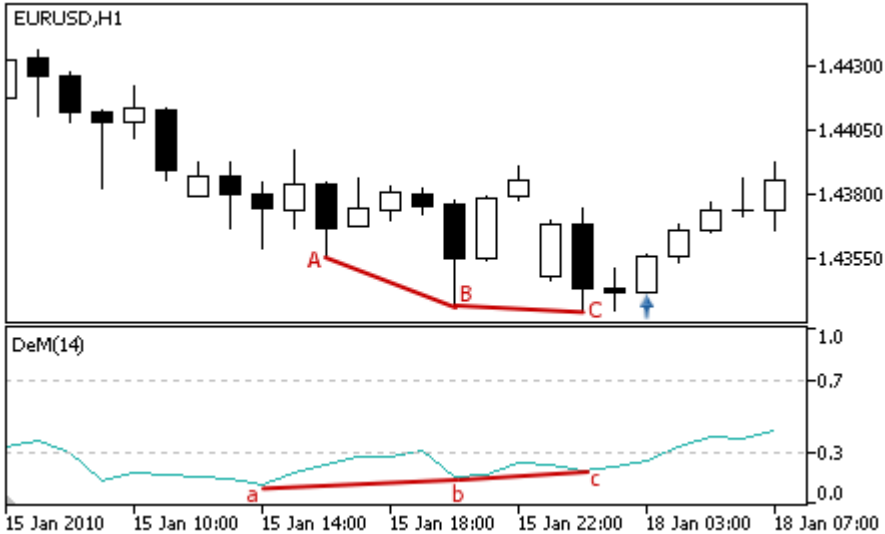

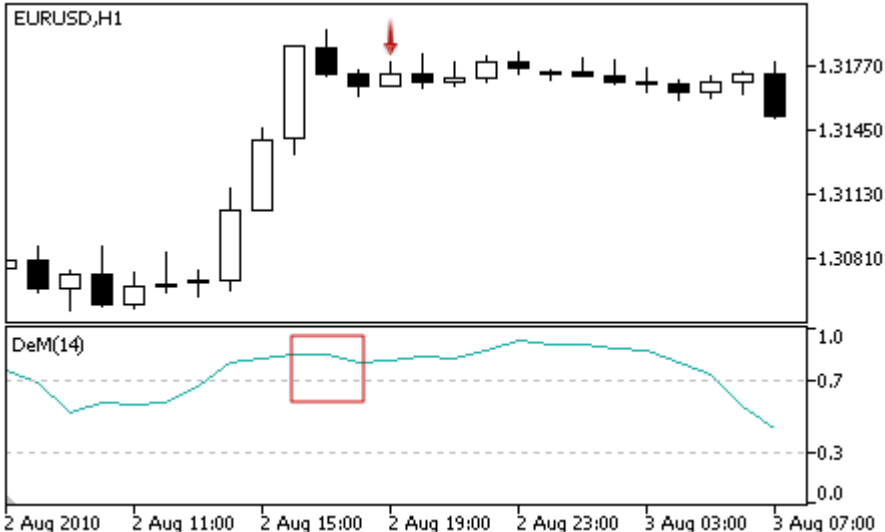

Signals of the Oscillator DeMarker

This module of signals is based on the market models of the oscillator [DeMarker](#). The mechanism of making trade decisions based on signals obtained from the modules is described in a [separate section](#).

Conditions of Generation of Signals

Below you can find the description of conditions when the module passes a signal to an Expert Advisor.

Signal Type	Description of Conditions
For buying	<ul style="list-style-type: none"> Reverse behind the oversold level – the oscillator turned upwards and its value at the analyzed bar is behind the oversold level (default value is 0.3).  Divergence – the first analyzed bottom of the oscillator is higher than the previous one, and the corresponding price bottom is lower than the previous one.  Double divergence – the oscillator form three consequent bottoms, each of them is higher than the previous one; and the price formed three corresponding bottoms, and each of them is lower than the previous one. 

Signal Type	Description of Conditions
	 <p>The top chart is a candlestick plot for EURUSD on an H1 timeframe. It shows a series of price bars from January 15, 2010, to January 18, 2010. A red line connects three points labeled A, B, and C, indicating a downward trend. The bottom chart is the DeM(14) oscillator, showing a green line with points a, b, and c marked, corresponding to the price points above. The oscillator line is below the 0.7 level.</p>
For selling	<ul style="list-style-type: none"> • Reverse behind the overbought level – the oscillator turned downwards and its value at the analyzed bar is behind the overbought level (default value is 0.7).  <p>The top chart is a candlestick plot for EURUSD on an H1 timeframe. It shows a series of price bars from August 2, 2010, to August 3, 2010. A red arrow points to a bar where the price starts to decline after an upward trend. The bottom chart is the DeM(14) oscillator, showing a green line with a peak highlighted by a red box. The oscillator line is above the 0.7 level.</p> <ul style="list-style-type: none"> • Divergence – the first analyzed peak of the oscillator is lower than the previous one, and the corresponding price peak is higher than the previous peak.

Signal Type	Description of Conditions
	 <p>EURUSD,H1</p> <p>DeM(14)</p> <ul style="list-style-type: none"> • Double divergence – the oscillator formed three consequent peaks, each of them is lower than the previous one; and the price formed three corresponding peaks, each of them is higher than the previous one.  <p>EURUSD,H1</p> <p>DeM(14)</p>
No objections to buying	Value of the oscillator grows at the analyzed bar.
No objections to selling	Value of the oscillator falls at the analyzed bar.

Note

Depending on the mode of operation of an Expert Advisor ("Every tick" or "Open prices only") an analyzed bar is either the current bar (with index 0), or the last formed bar (with index 1).

Adjustable Parameters

This module has the following adjustable parameters:

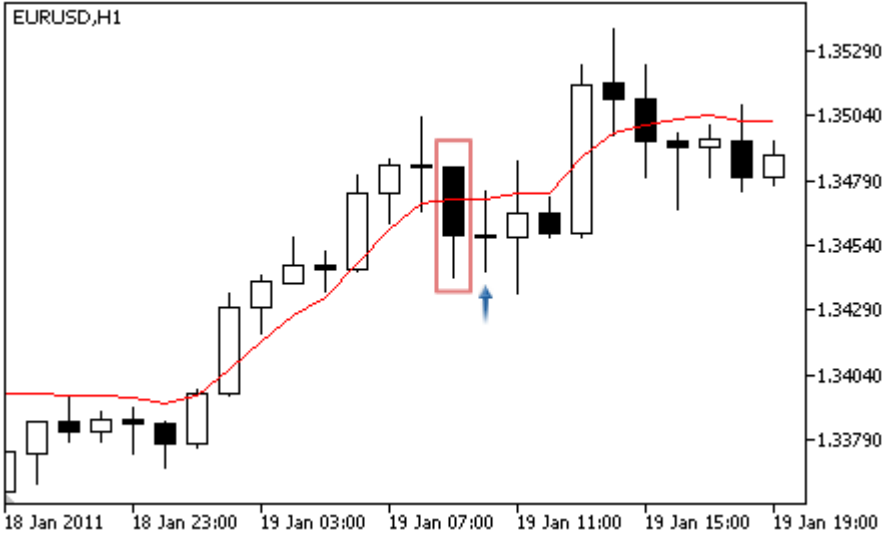

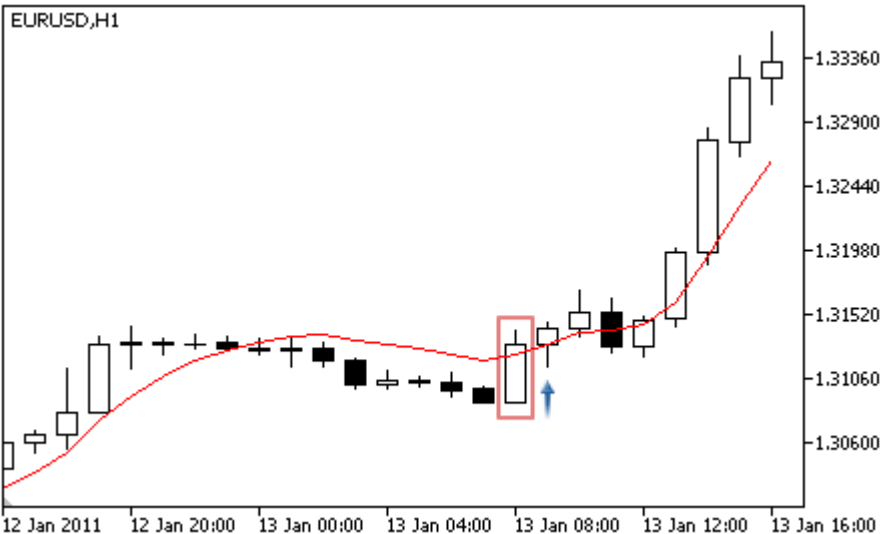

Parameter	Description
Weight	Weight of signal of the module in the interval 0 to 1.
PeriodDeM	Period of calculation of the oscillator.

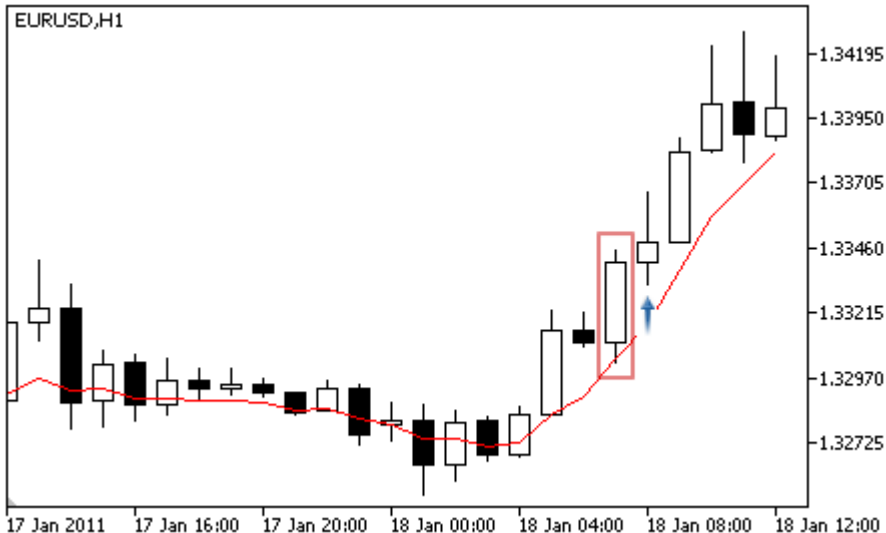

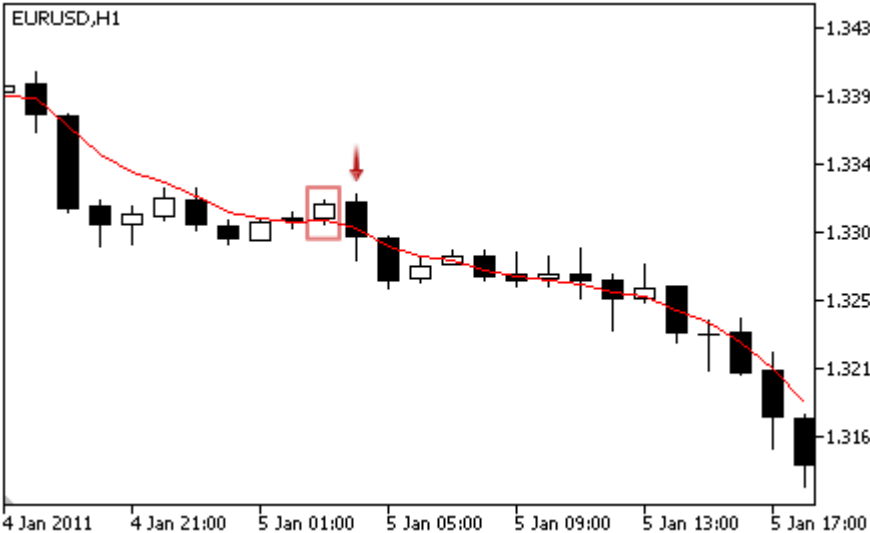

Signals of the Indicator Double Exponential Moving Average

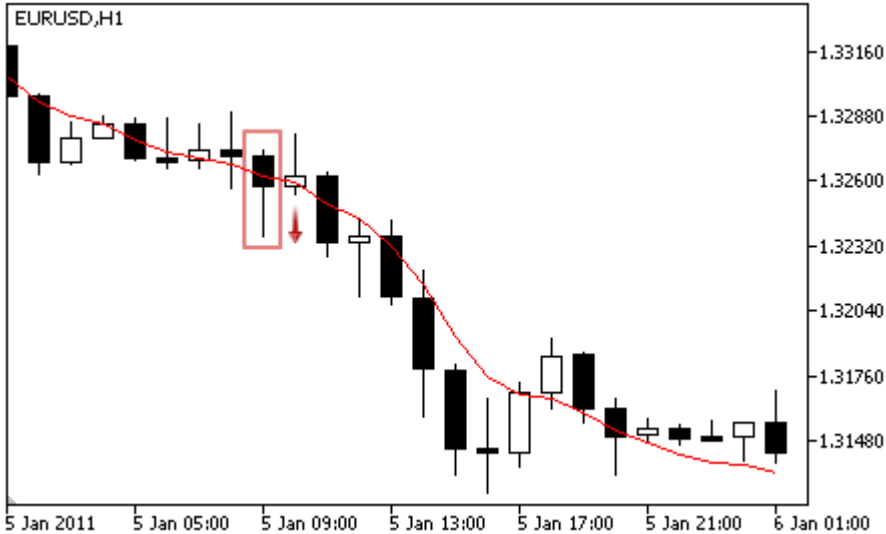

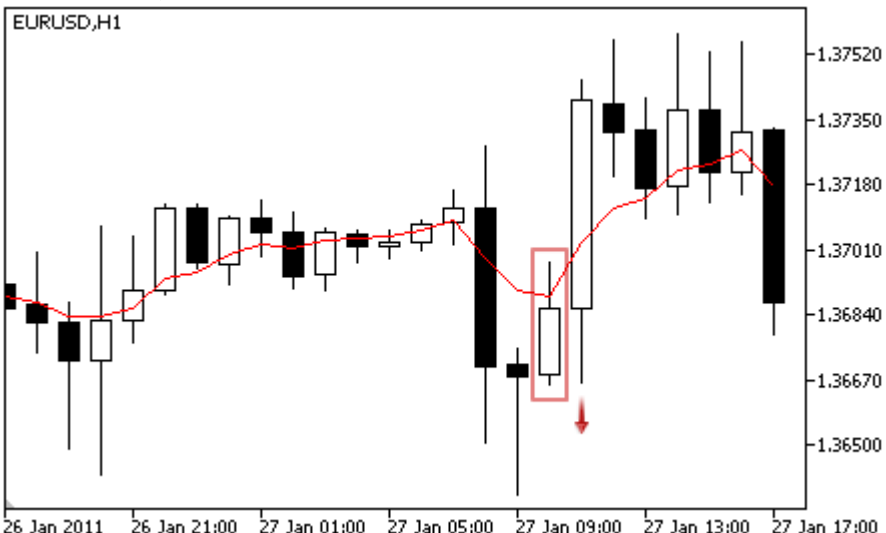

This module is based on the market models of the indicator [Double Exponential Moving Average](#). The mechanism of making trade decisions based on signals obtained from the modules is described in a [separate section](#).

Conditions of Generation of Signals

Below you can find the description of conditions when the module passes a signal to an Expert Advisor.

Signal Type	Description of Conditions
For buying	<ul style="list-style-type: none"> Failed breakout. The price has crossed the indicator downwards (the Open price of the analyzed bar is above the indicator and the Close price is below the indicator) and the indicator rises (weak signal for a roll-back from the indicator line).  Moving Average crossover. The price has crossed the indicator upwards (the Open price of the analyzed bar is below the indicator and the Close price is above the indicator) and the indicator rises (strong signal). 

Signal Type	Description of Conditions
	<ul style="list-style-type: none"> • Formed breakout. The lower shadow of the bar has crossed the indicator (the Open and Close prices of the analyzed bar are above the indicator, and the Low price is below the indicator) and the indicator rises (signal for a roll-back from the indicator line).  <p>The chart displays EURUSD on an H1 timeframe. A red moving average line is shown. A candlestick is highlighted with a red box, indicating a breakout where the lower shadow crosses the indicator. The indicator line is shown rising, signaling a potential roll-back.</p>
For selling	<ul style="list-style-type: none"> • Failed breakout. The price has crossed the indicator upwards (the Open price of the analyzed bar is below the indicator and the Close price is above the indicator) and the indicator falls (weak signal for a roll-back from the indicator line).  <p>The chart displays EURUSD on an H1 timeframe. A red moving average line is shown. A candlestick is highlighted with a red box, indicating a failed breakout where the price crosses the indicator upwards. The indicator line is shown falling, signaling a potential roll-back.</p> <ul style="list-style-type: none"> • Moving Average crossover. The price has crossed the indicator downwards (the Open price of the analyzed bar is above the indicator and the Close price is below the indicator) and the indicator falls (strong signal).

Signal Type	Description of Conditions
	 <p>• Formed breakout. The upper shadow of the bar has crossed the indicator (the Open and Close prices of the analyzed bar are below the indicator, and the High price is above the indicator) and the indicator falls (weak signal for a roll-back from the indicator line).</p> 
No objections to buying	The price is above the indicator.
No objections to selling	The price is below the indicator.

Note

Depending on the mode of operation of an Expert Advisor ("Every tick" or "Open prices only") an analyzed bar is either the current bar (with index 0), or the last formed bar (with index 1).

Adjustable Parameters

This module has the following adjustable parameters:

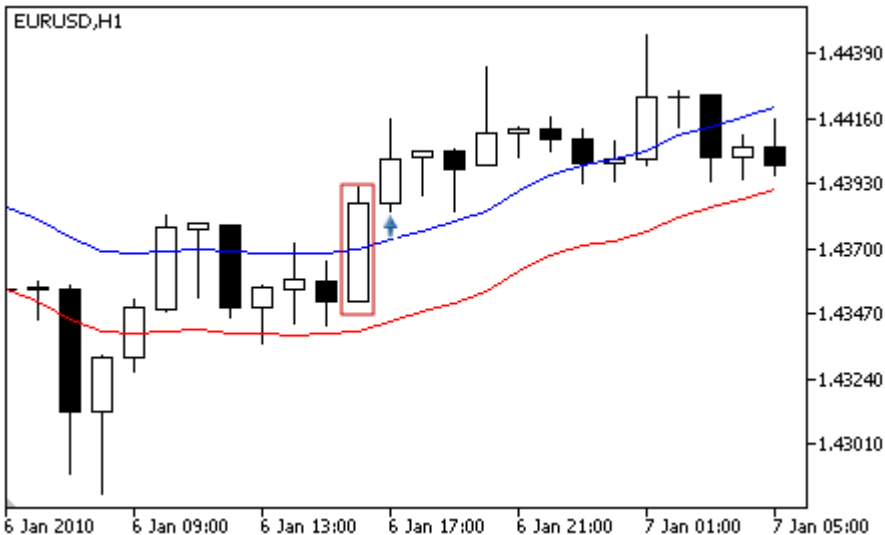

Parameter	Description
Weight	Weight of signal of the module in the interval 0 to 1.
PeriodMA	Period of averaging of the indicator.
Shift	Shift of the indicator along the time axis (in bars).
Method	Method of averaging.
Applied	A price series used for calculation of the indicator.

Signals of the Indicator Envelopes

This module of signals is based on the market models of the indicator [Envelopes](#). The mechanism of making trade decisions based on signals obtained from the modules is described in a [separate section](#).

Conditions of Generation of Signals

Below you can find the description of conditions when the module passes a signal to an Expert Advisor.

Signal Type	Description of Conditions
For buying	<ul style="list-style-type: none"> The price is near the lower line of the indicator at the analyzed bar.  <ul style="list-style-type: none"> The price crossed the upper line of the indicator at the analyzed bar. 
For selling	<ul style="list-style-type: none"> The price is near the upper line of the indicator at the analyzed bar.

Signal Type	Description of Conditions
	 <p>EURUSD, H1</p> <ul style="list-style-type: none"> The price crossed the lower line of the indicator at the analyzed bar.  <p>EURUSD, H1</p>
No objections to buying	No signals.
No objections to selling	No signals.

Note

Depending on the mode of operation of an Expert Advisor ("Every tick" or "Open prices only") an analyzed bar is either the current bar (with index 0), or the last formed bar (with index 1).

Adjustable Parameters

This module has the following adjustable parameters:

Parameter	Description
Weight	Weight of signal of the module in the interval 0 to 1.
PeriodMA	Period of calculation of the indicator.
Shift	Shift of the indicator along the time axis (in bars).
Method	Method of averaging.
Applied	A price series used for calculation of the indicator.
Deviation	Deviation of the envelope borders from the center line (MA) in percentage terms.

Signals of the Indicator Fractal Adaptive Moving Average

This module of signals is based on the market models of the indicator [Fractal Adaptive Moving Average](#). The mechanism of making trade decisions based on signals obtained from the modules is described in a [separate section](#).

Conditions of Generation of Signals

Below you can find the description of conditions when the module passes a signal to an Expert Advisor.

Signal Type	Description of Conditions
For buying	<ul style="list-style-type: none"> Failed breakout. The price has crossed the indicator downwards (the Open price of the analyzed bar is above the indicator and the Close price is below the indicator) and the indicator rises (weak signal for a roll-back from the indicator line).  Moving Average crossover. The price has crossed the indicator upwards (the Open price of the analyzed bar is below the indicator and the Close price is above the indicator) and the indicator rises (strong signal). 

Signal Type	Description of Conditions
	<ul style="list-style-type: none"> • Formed breakout. The lower shadow of the bar has crossed the indicator (the Open and Close prices of the analyzed bar is above the indicator, and the Low price is below the indicator) and the indicator rises (signal for a roll-back from the indicator line). 
For selling	<ul style="list-style-type: none"> • Failed breakout. The price has crossed the indicator upwards (the Open price of the analyzed bar is below the indicator and the Close price is above the indicator) and the indicator falls (weak signal for a roll-back from the indicator line).  <ul style="list-style-type: none"> • Moving Average crossover. The price has crossed the indicator downwards (the Open price of the analyzed bar is above the indicator and the Close price is below the indicator) and the indicator falls (strong signal).

Signal Type	Description of Conditions
	 <p>• Formed breakout. The upper shadow of the bar has crossed the indicator (the Open and Close prices of the analyzed bar are below the indicator, and the High price is above the indicator) and the indicator falls (weak signal for a roll-back from the indicator line).</p> 
No objections to buying	The price is above the indicator.
No objections to selling	The price is below the indicator.

Note

Depending on the mode of operation of an Expert Advisor ("Every tick" or "Open prices only") an analyzed bar is either the current bar (with index 0), or the last formed bar (with index 1).

Adjustable Parameters

This module has the following adjustable parameters:

Parameter	Description
Weight	Weight of signal of the module in the interval 0 to 1.
PeriodMA	Period of averaging of the indicator.
Shift	Shift of the indicator along the time axis (in bars).
Method	Method of averaging.
Applied	A price series used for calculation of the indicator.

Signals of the Intraday Time Filter

This module is based on the assumption that the efficiency of market models changes in time. Using this module, you can filter signals received from the other modules by hour and days of week. It allows increasing the quality of generated signals due to cutting off the unfavorable time periods. The mechanism of making trade decisions on the basis of signals of the modules is described in a [separate section](#).

Conditions of Generation of Signals

Below you can find the description of conditions when the module passes a signal to an Expert Advisor.

Signal Type	Description of Conditions
For buying	No signals.
For selling	No signals.
No objections to buying	The current date and time meet the specified parameters.
No objections to selling	The current date and time meet the specified parameters.

Adjustable Parameters

This module has the following adjustable parameters:

Parameter	Description
Weight	Weight of signal of the module in the interval 0 to 1.
GoodHourOfDay	Number of the only hour of day (from 0 to 23) when trade signals will be enabled. If the value is -1, the signals will be enabled through the whole day.
BadHoursOfDay	The bit field. Each bit of this field corresponds to an hour of day (0 bit - 0 hour, ..., 23 bit - 23-rd hour). If the value of a bit is equal to 0, trade signals will be enabled during the corresponding hour. If the value of a bit is equal to 1, trade signals will be disabled during the corresponding hour. A specified number is represented as a binary number and is used as bit mask. Disabled hours have higher priority than the enabled ones.
GoodDayOfWeek	Number of the only day of week (from 0 to 6, where 0 is Sunday), when trade signals will be

Parameter	Description
	enabled. If the value is -1, the signals will be enabled on any day.
BadDaysOfWeek	<p>The bit field. Each bit of this field corresponds to a day of week (0 bit - Sunday, ..., 6 bit - Saturday). If the value of a bit is equal to 0, trade signals will be enabled during the corresponding day. If the value of a bit is equal to 1, trade signals will be disabled during the corresponding day. A specified number is represented as a binary number and is used as bit mask.</p> <p>Disabled days have higher priority than the enabled ones.</p>

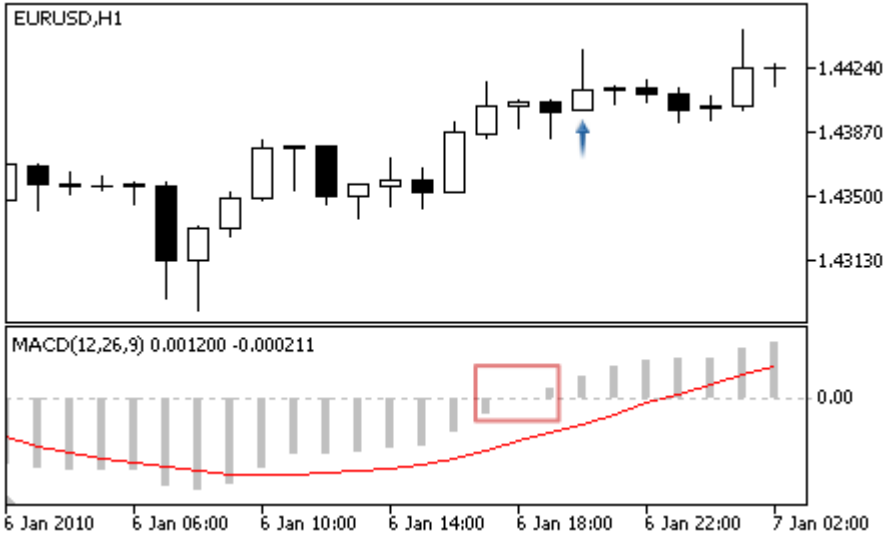

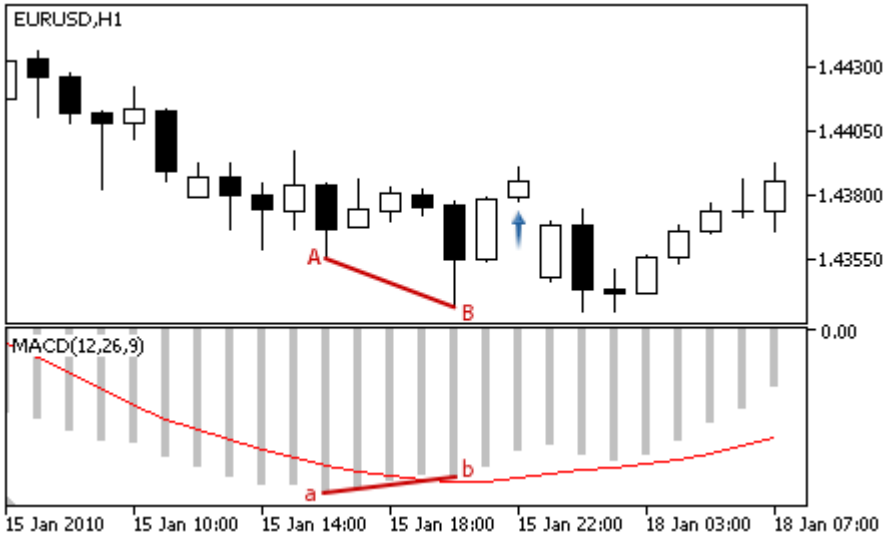

Signals of the Oscillator MACD

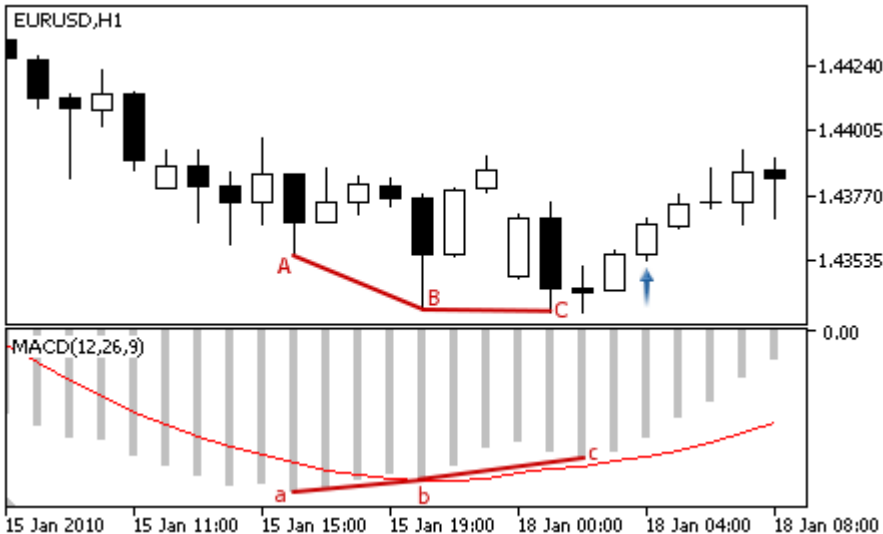

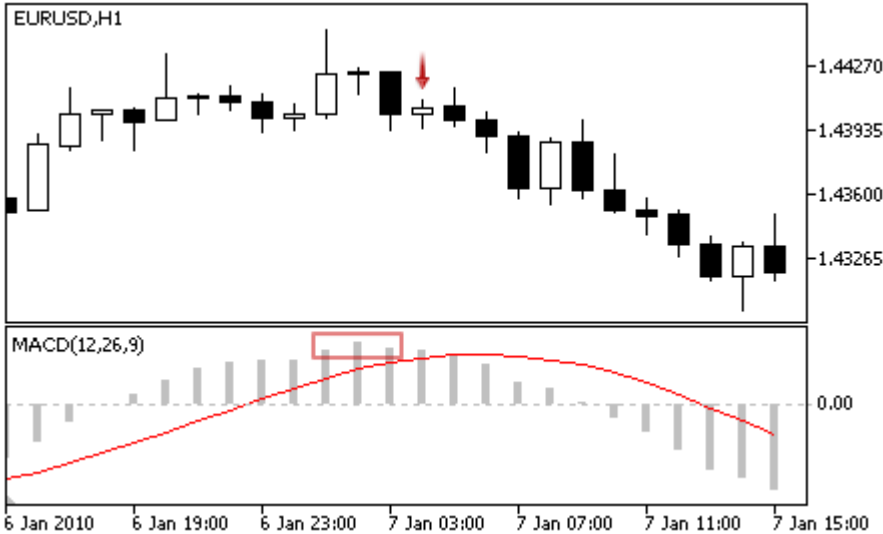

This module of signals is based on the market models of the oscillator [MACD](#). The mechanism of making trade decisions based on signals obtained from the modules is described in a [separate section](#).

Conditions of Generation of Signals

Below you can find the description of conditions when the module passes a signal to an Expert Advisor.

Signal Type	Description of Conditions
For buying	<ul style="list-style-type: none"> Reverse – the oscillator turned upwards (the oscillator rises at the analyzed bar and falls at the previous one).  Crossover of the main and signal line – the main line is above the signal line at the analyzed bar and below the signal line at the previous one.  Crossing the zero level – the main line is above the zero level at the analyzed bar and below the zero level at the previous one. 

Signal Type	Description of Conditions
	<div data-bbox="435 315 1321 846">  <p>EURUSD,H1</p> <p>MACD(12,26,9) 0.001200 -0.000211</p> </div> <ul style="list-style-type: none"> • Divergence – the first analyzed bottom of the oscillator is higher than the previous one, and the corresponding price bottom is lower than the previous one. <div data-bbox="435 958 1321 1489">  <p>EURUSD,H1</p> <p>MACD(12,26,9)</p> </div> <ul style="list-style-type: none"> • Double divergence – the oscillator forms three consequent bottoms, each of them is higher than the previous one; and the price formed three corresponding bottoms, and each of them is lower than the previous one.

Signal Type	Description of Conditions
	 <p>EURUSD,H1</p> <p>MACD(12,26,9)</p> <p>15 Jan 2010 15 Jan 11:00 15 Jan 15:00 15 Jan 19:00 18 Jan 00:00 18 Jan 04:00 18 Jan 08:00</p>
For selling	<ul style="list-style-type: none"> • Reverse – the oscillator turned downwards (the oscillator falls at the analyzed bar and rises at the previous one).  <p>EURUSD,H1</p> <p>MACD(12,26,9)</p> <p>6 Jan 2010 6 Jan 19:00 6 Jan 23:00 7 Jan 03:00 7 Jan 07:00 7 Jan 11:00 7 Jan 15:00</p> <ul style="list-style-type: none"> • Crossover of the main and signal line – the main line is below the signal line at the analyzed bar and above the signal line at the previous one.

Signal Type	Description of Conditions
	<div data-bbox="432 315 1321 846"> <p>EURUSD,H1</p> <p>MACD(12,26,9)</p> <p>6 Jan 2010 6 Jan 19:00 6 Jan 23:00 7 Jan 03:00 7 Jan 07:00 7 Jan 11:00 7 Jan 15:00</p> </div> <ul style="list-style-type: none"> • Crossing the zero level – the main line is below the zero level at the analyzed bar and above the zero level at the previous one. <div data-bbox="432 958 1321 1489"> <p>EURUSD,H1</p> <p>MACD(12,26,9)</p> <p>6 Jan 2010 6 Jan 21:00 7 Jan 01:00 7 Jan 05:00 7 Jan 09:00 7 Jan 13:00 7 Jan 17:00</p> </div> <ul style="list-style-type: none"> • Divergence – the first analyzed peak of the oscillator is lower than the previous one, and the corresponding price peak is higher than the previous peak.

Signal Type	Description of Conditions
	<div data-bbox="432 315 1321 846"> <p>EURUSD,H1</p> <p>MACD(12,26,9)</p> <p>22 Jan 2010 22 Jan 05:00 22 Jan 09:00 22 Jan 13:00 22 Jan 17:00 22 Jan 21:00 25 Jan 02:00</p> </div> <ul style="list-style-type: none"> • Double divergence – the oscillator formed three consequent peaks, each of them is lower than the previous one; and the price formed three corresponding peaks, each of them is higher than the previous one. <div data-bbox="432 987 1321 1518"> <p>EURUSD,H1</p> <p>MACD(12,26,9)</p> <p>11 Jan 2010 11 Jan 05:00 11 Jan 09:00 11 Jan 13:00 11 Jan 17:00 11 Jan 21:00 12 Jan 01:00</p> </div>
No objections to buying	Value of the oscillator grows at the analyzed bar.
No objections to selling	Value of the oscillator falls at the analyzed bar.

Note

Depending on the mode of operation of an Expert Advisor ("Every tick" or "Open prices only") an analyzed bar is either the current bar (with index 0), or the last formed bar (with index 1).

Adjustable Parameters

This module has the following adjustable parameters:

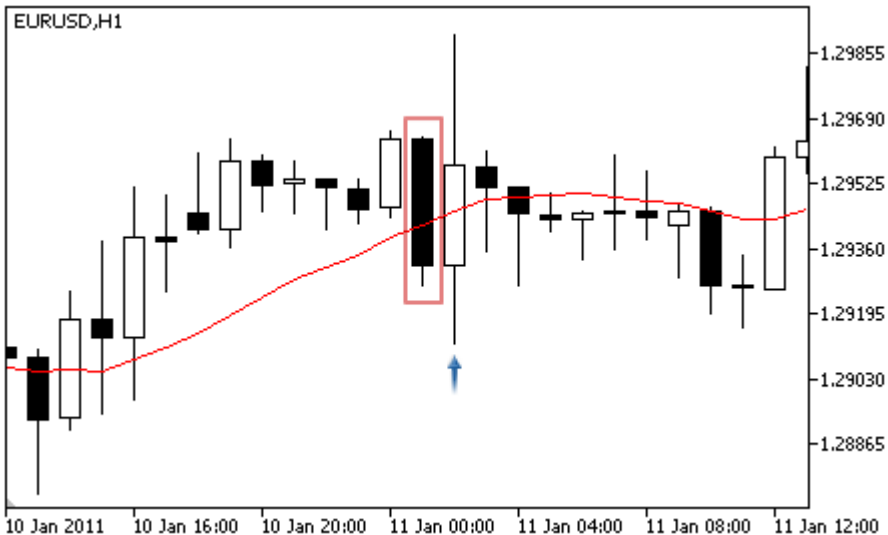

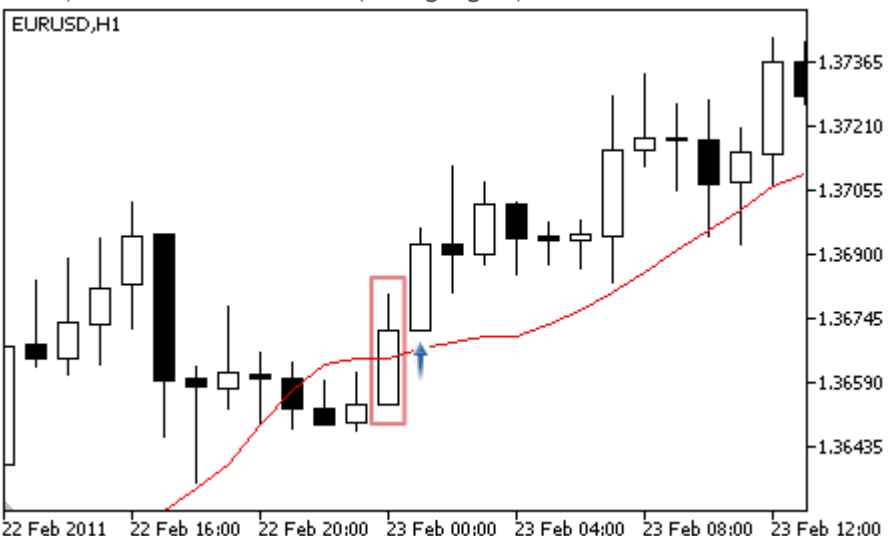

Parameter	Description
Weight	Weight of signal of the module in the interval 0 to 1.
PeriodFast	Period of calculation of the fast EMA.
PeriodSlow	Period of calculation of the slow EMA.
PeriodSignal	Period of smoothing.
Applied	A price series used for calculation of the oscillator.

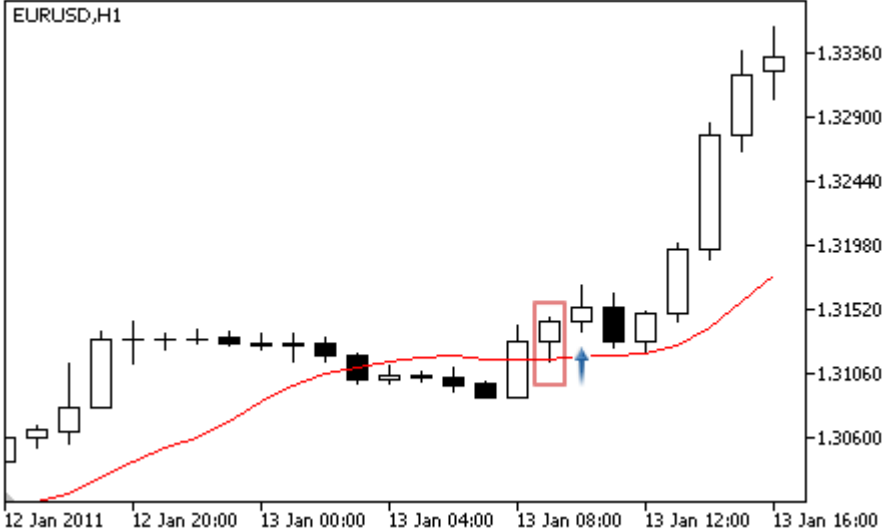

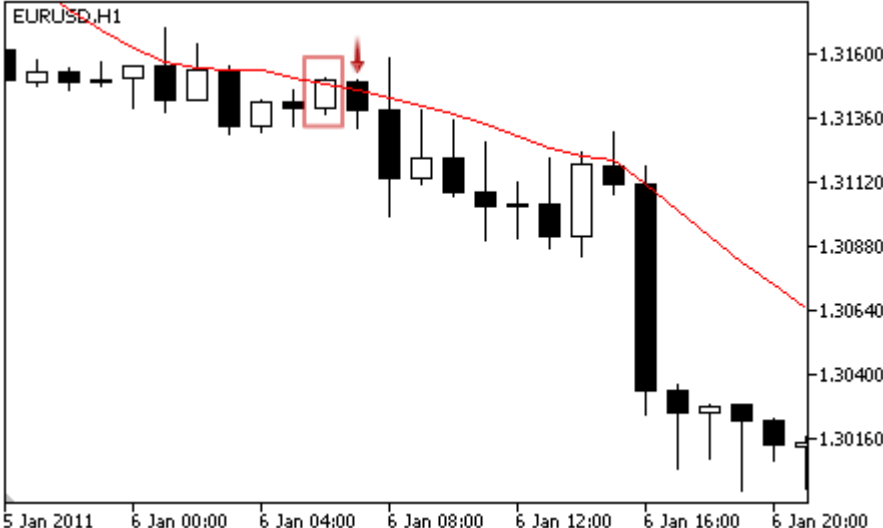

Signals of the Indicator Moving Average

This module of signals is based on the market models of the indicator [Moving Average](#). The mechanism of making trade decisions based on signals obtained from the modules is described in a [separate section](#).

Conditions of Generation of Signals

Below you can find the description of conditions when the module passes a signal to an Expert Advisor.

Signal Type	Description of Conditions
For buying	<ul style="list-style-type: none"> Failed breakout. The price has crossed the indicator downwards (the Open price of the analyzed bar is above the indicator and the Close price is below the indicator) and the indicator rises (weak signal for a roll-back from the indicator line).  Moving Average crossover. The price has crossed the indicator upwards (the Open price of the analyzed bar is below the indicator and the Close price is above the indicator) and the indicator rises (strong signal). 

Signal Type	Description of Conditions
	<ul style="list-style-type: none"> • Formed breakout. The lower shadow of the bar has crossed the indicator (the Open and Close prices of the analyzed bar are above the indicator, and the Low price is below the indicator) and the indicator rises (weak signal for a roll-back from the indicator line). 
For selling	<ul style="list-style-type: none"> • Failed breakout. The price has crossed the indicator upwards (the Open price of the analyzed bar is below the indicator and the Close price is above the indicator) and the indicator falls (weak signal).  <ul style="list-style-type: none"> • Moving Average crossover. The price has crossed the indicator downwards (the Open price of the analyzed bar is above the indicator and the Close price is below the indicator) and the indicator falls (strong signal).

Signal Type	Description of Conditions
	 <ul style="list-style-type: none"> • Formed breakout. The upper shadow of the bar has crossed the indicator (the Open and Close prices of the analyzed bar are below the indicator, and the High price is above the indicator) and the indicator falls (weak signal for a roll-back from the indicator line). 
No objections to buying	The price is above the indicator.
No objections to selling	The price is below the indicator.

Note

Depending on the mode of operation of an Expert Advisor ("Every tick" or "Open prices only") an analyzed bar is either the current bar (with index 0), or the last formed bar (with index 1).

Adjustable Parameters

This module has the following adjustable parameters:

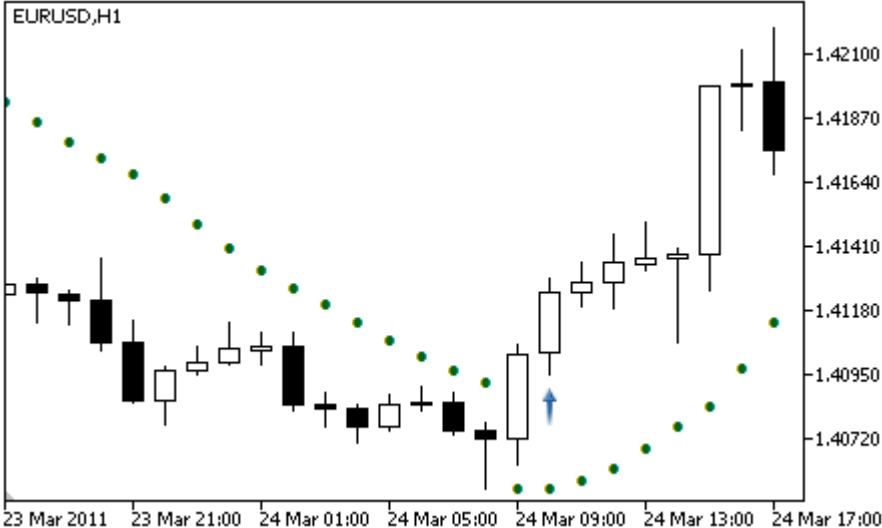

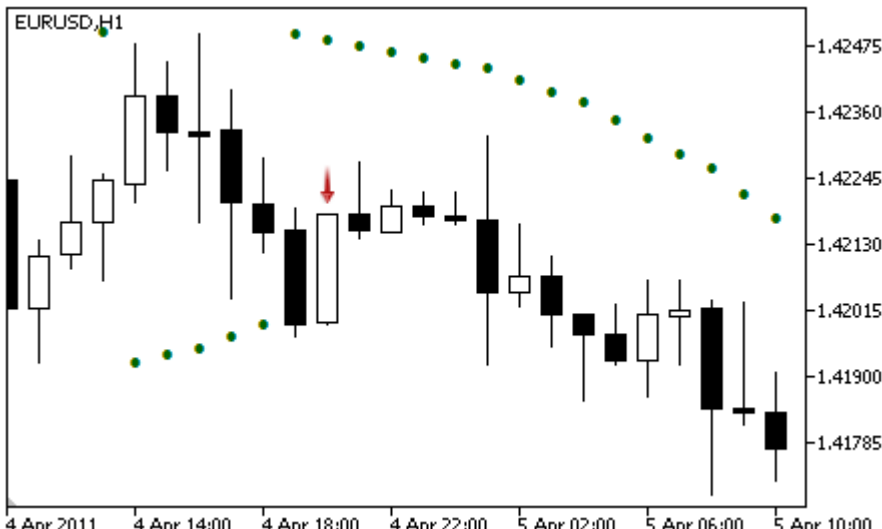

Parameter	Description
Weight	Weight of signal of the module in the interval 0 to 1.
PeriodMA	Period of averaging of the indicator.
Shift	Shift of the indicator along the time axis (in bars).
Method	Method of averaging.
Applied	A price series used for calculation of the indicator.

Signals of the indicator Parabolic SAR

This module of signals is based on the market models of the indicator [Parabolic SAR](#). The mechanism of making trade decisions based on signals obtained from the modules is described in a [separate section](#).

Conditions of Generation of Signals

Below you can find the description of conditions when the module passes a signal to an Expert Advisor.

Signal Type	Description of Conditions
For buying	<p>Reverse — the indicator is below the price at the analyzed bar and above the price at the previous one.</p>  <p>The chart displays EURUSD on an H1 timeframe from March 23 to March 24, 2011. The price is shown as candlesticks, and the Parabolic SAR indicator is represented by green dots. A blue arrow points upwards from the indicator to the price bar, indicating a 'Reverse' buy signal.</p>
For selling	<p>Reverse — the indicator is above the price at the analyzed bar and below the price at the previous one.</p>  <p>The chart displays EURUSD on an H1 timeframe from April 4 to April 5, 2011. The price is shown as candlesticks, and the Parabolic SAR indicator is represented by green dots. A red arrow points downwards from the indicator to the price bar, indicating a 'Reverse' sell signal.</p>
No objections	The price is above the indicator.

Signal Type	Description of Conditions
to buying	
No objections to selling	The price is below the indicator.

Note

Depending on the mode of operation of an Expert Advisor ("Every tick" or "Open prices only") an analyzed bar is either the current bar (with index 0), or the last formed bar (with index 1).

Adjustable Parameters

This module has the following adjustable parameters:

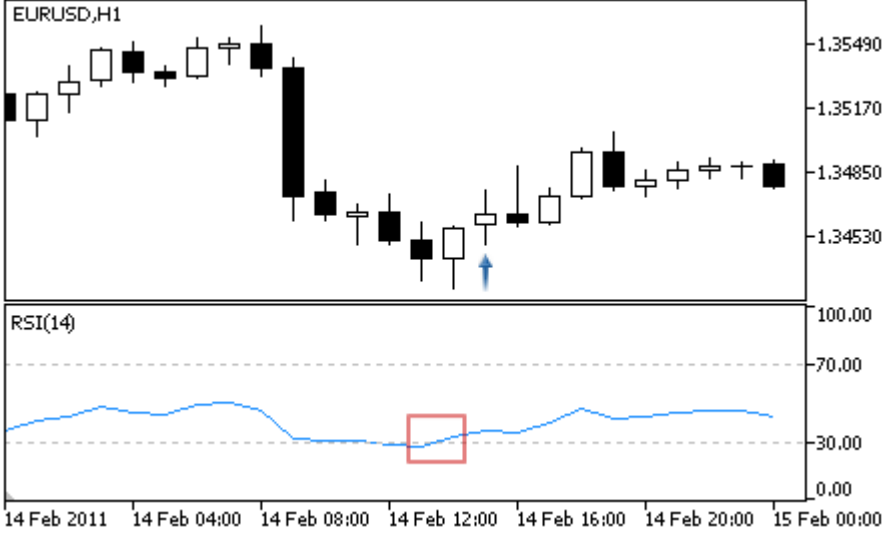

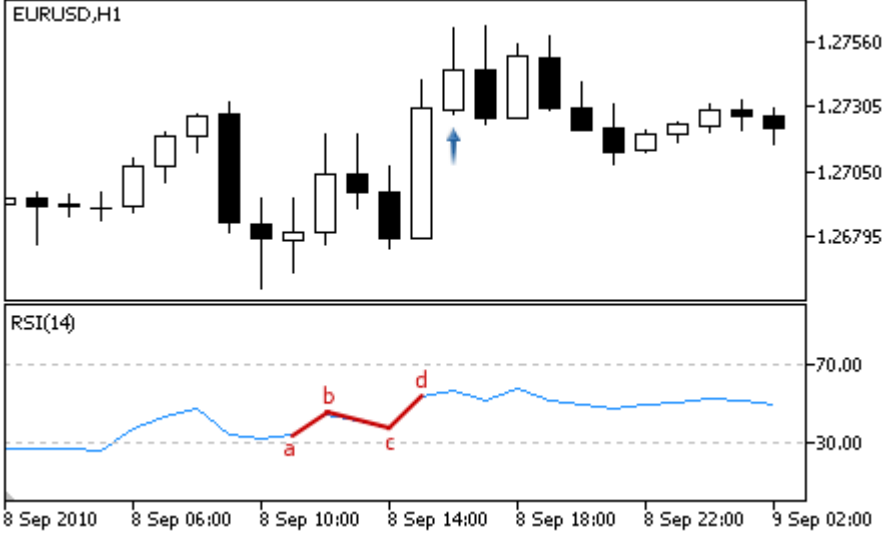

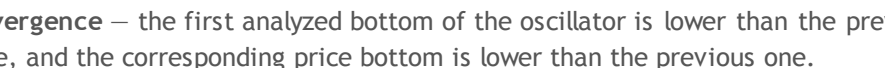

Parameter	Description
Weight	Weight of signal of the module in the interval 0 to 1.
Step	The step of price increment.
Maximum	Maximum rate of the speed of convergence of the indicator with the price.

Signals of the Oscillator Relative Strength Index

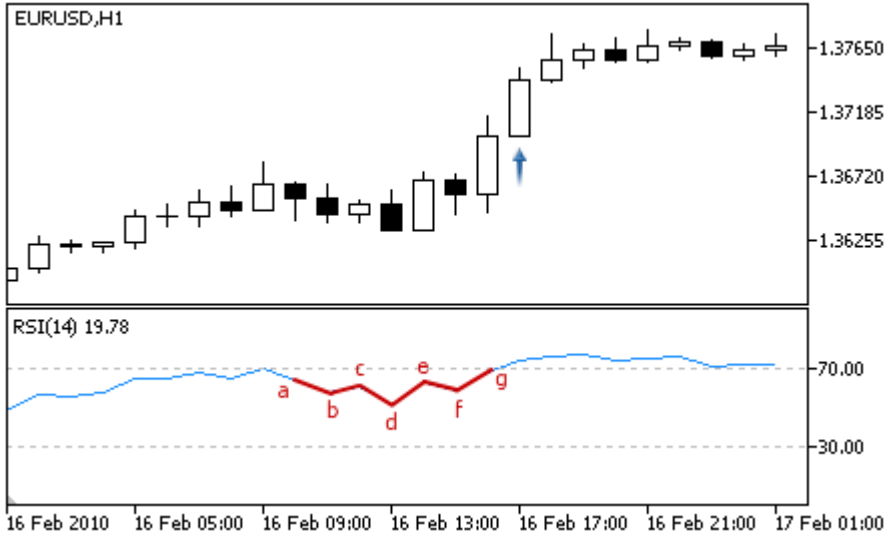

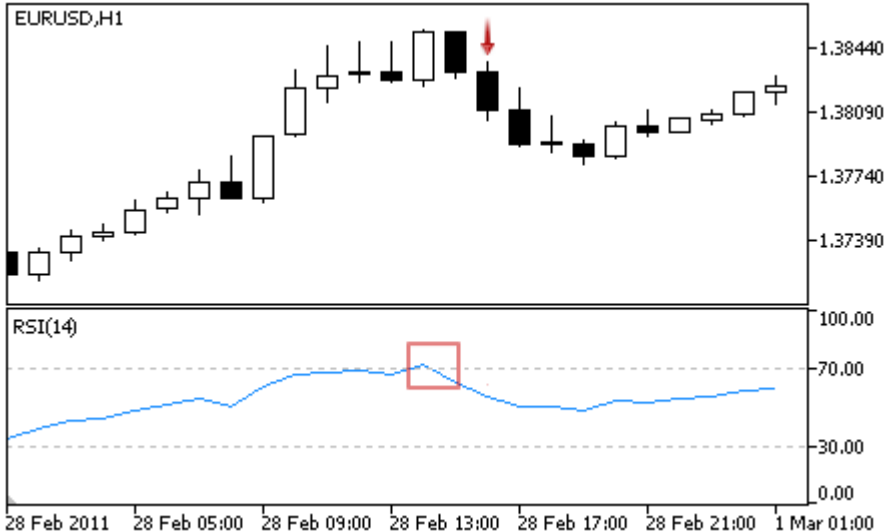

This module of signals is based on the market models of the oscillator [Relative Strength Index](#). The mechanism of making trade decisions based on signals obtained from the modules is described in a [separate section](#).

Conditions of Generation of Signals

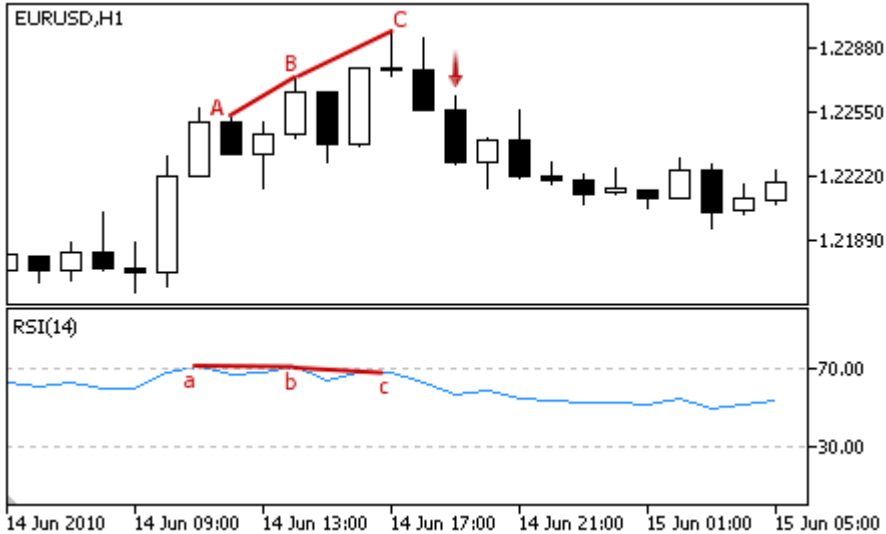

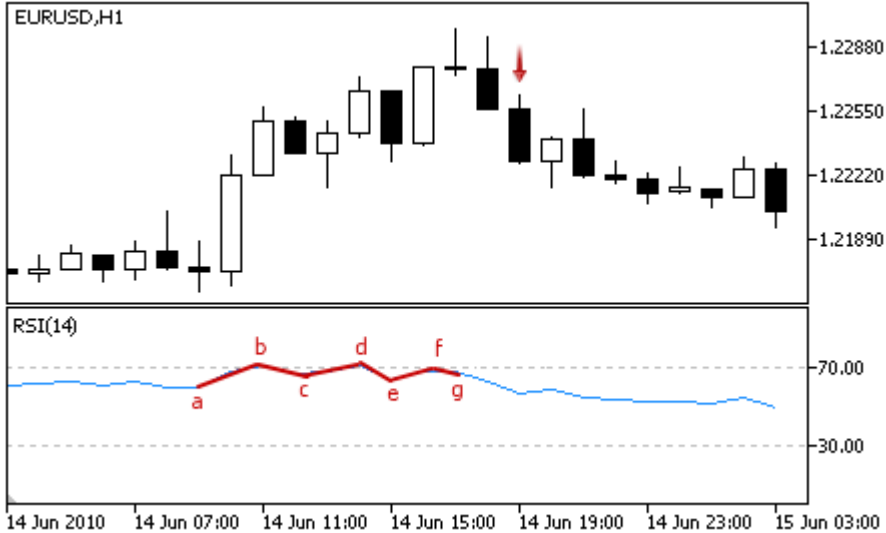

Below you can find the description of conditions when the module passes a signal to an Expert Advisor.

Signal Type	Description of Conditions
For buying	<ul style="list-style-type: none"> Reverse behind the oversold level – the oscillator turned upwards and its value at the analyzed bar is behind the oversold level (default value is 30).  Failed swing – the oscillator rises higher than the previous peak at the analyzed bar.  Divergence – the first analyzed bottom of the oscillator is lower than the previous one, and the corresponding price bottom is lower than the previous one. 

Signal Type	Description of Conditions
	<div data-bbox="432 315 1321 846"> <p>EURUSD, H1</p> <p>RSI(14)</p> <p>20 Aug 2010 20 Aug 10:00 20 Aug 14:00 20 Aug 18:00 20 Aug 22:00 23 Aug 02:00 23 Aug 06:00</p> </div> <ul style="list-style-type: none"> • Double divergence – the oscillator form three consequent bottoms, each of them is higher than the previous one; and the price formed three corresponding bottoms, and each of them is lower than the previous one. <div data-bbox="432 992 1321 1523"> <p>EURUSD, H1</p> <p>RSI(14)</p> <p>11 Nov 2010 11 Nov 19:00 11 Nov 23:00 12 Nov 03:00 12 Nov 07:00 12 Nov 11:00 12 Nov 15:00</p> </div> <ul style="list-style-type: none"> • Head/Shoulders – the oscillator formed three consequent bottoms, and the mid one is lower than the others.

Signal Type	Description of Conditions
	 <p>EURUSD,H1</p> <p>RSI(14) 19.78</p> <p>16 Feb 10:00 16 Feb 16:00 16 Feb 22:00 17 Feb 01:00</p>
For selling	<ul style="list-style-type: none"> • Reverse behind the overbought level – the oscillator turned downwards and its value at the analyzed bar is behind the overbought level (default value is 70).  <p>EURUSD,H1</p> <p>RSI(14)</p> <p>28 Feb 08:00 28 Feb 14:00 28 Feb 20:00 1 Mar 01:00</p> <ul style="list-style-type: none"> • Failed swing – the oscillator falls lower than the previous bottom at the analyzed bar.

Signal Type	Description of Conditions
	<div data-bbox="430 313 1316 840"> <p>EURUSD,H1</p> <p>RSI(14)</p> <p>23 Aug 2010 23 Aug 06:00 23 Aug 10:00 23 Aug 14:00 23 Aug 18:00 23 Aug 22:00 24 Aug 02:00</p> </div> <ul style="list-style-type: none"> • Divergence – the first analyzed peak of the oscillator is lower than the previous one, and the corresponding price peak is higher than the previous peak. <div data-bbox="430 963 1316 1489"> <p>EURUSD,H1</p> <p>RSI(14)</p> <p>21 Sep 2010 22 Sep 02:00 22 Sep 06:00 22 Sep 10:00 22 Sep 14:00 22 Sep 18:00 22 Sep 22:00</p> </div> <ul style="list-style-type: none"> • Double divergence – the oscillator formed three consequent peaks, each of them is lower than the previous one; and the price formed three corresponding peaks, each of them is higher than the previous one.

Signal Type	Description of Conditions
	 <p>• Head/Shoulders — the oscillator formed three consequent peaks, and the mid one is higher than the others.</p> 
No objections to buying	Value of the oscillator grows at the analyzed bar.
No objections to selling	Value of the oscillator falls at the analyzed bar.

Note

Depending on the mode of operation of an Expert Advisor ("Every tick" or "Open prices only") an analyzed bar is either the current bar (with index 0), or the last formed bar (with index 1).

Adjustable Parameters

This module has the following adjustable parameters:

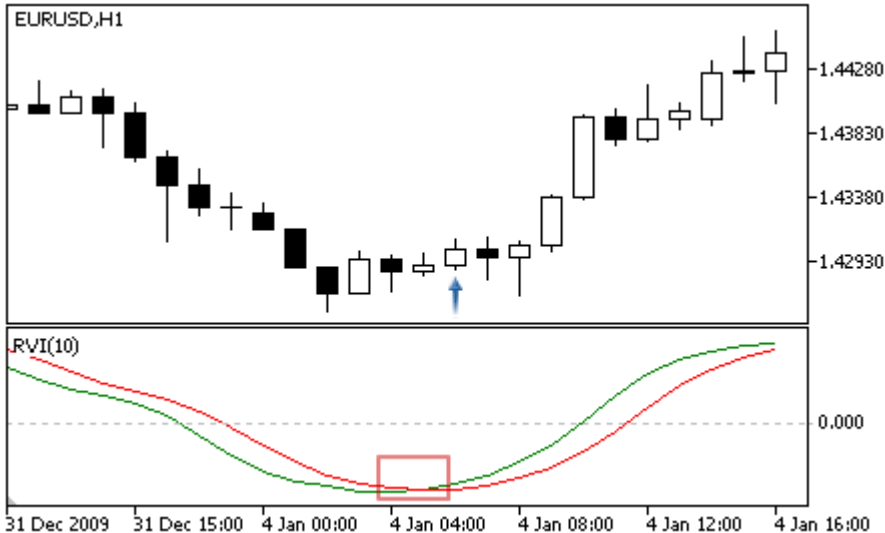

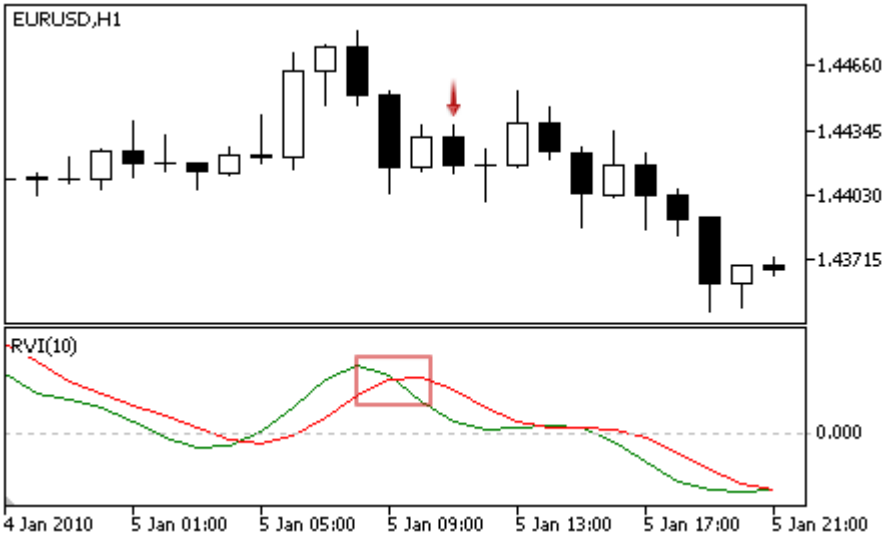

Parameter	Description
Weight	Weight of signal of the module in the interval 0 to 1.
PeriodRSI	Period of calculation of the oscillator.
Applied	A price series used for calculation of the oscillator.

Signals of the Oscillator Relative Vigor Index

This module of signals is based on the market models of the oscillator [Relative Vigor Index](#). The mechanism of making trade decisions based on signals obtained from the modules is described in a [separate section](#).

Conditions of Generation of Signals

Below you can find the description of conditions when the module passes a signal to an Expert Advisor.

Signal Type	Description of Conditions
For buying	<p>Crossing of the main and signal line – the main line is above the signal line at the analyzed bar and below the signal line at the previous one.</p> 
For selling	<p>Crossing of the main and signal line – the main line is below the signal line at the analyzed bar and above the signal line at the previous one.</p> 
No objections	Value of the oscillator grows at the analyzed bar.

Signal Type	Description of Conditions
to buying	
No objections to selling	Value of the oscillator falls at the analyzed bar.

Note

Depending on the mode of operation of an Expert Advisor ("Every tick" or "Open prices only") an analyzed bar is either the current bar (with index 0), or the last formed bar (with index 1).

Adjustable Parameters

This module has the following adjustable parameters:

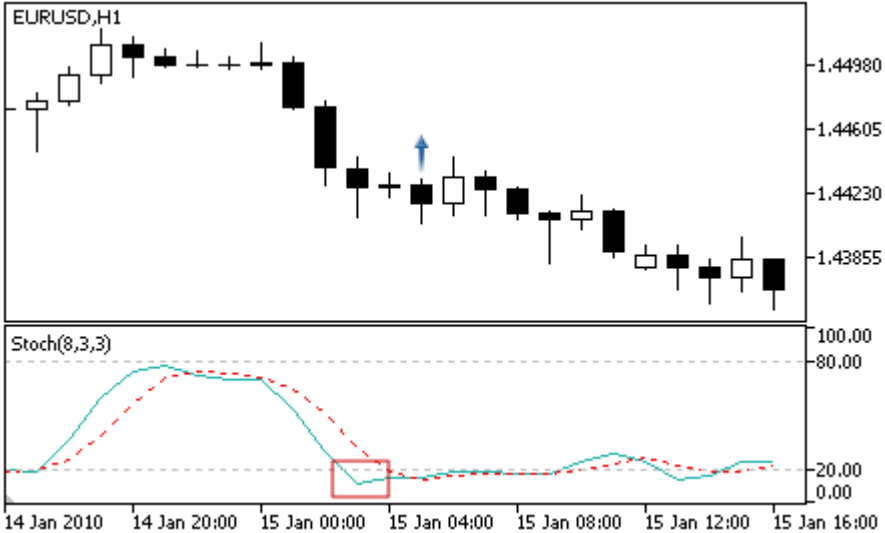

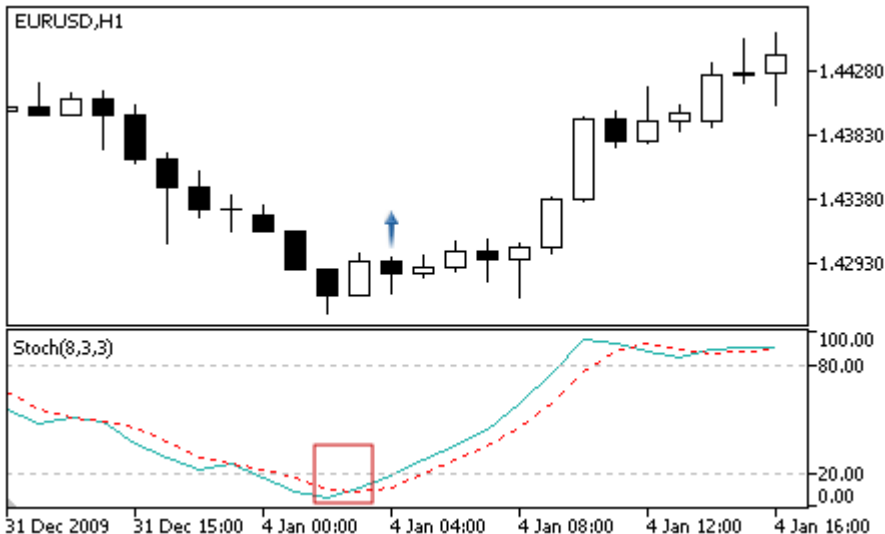

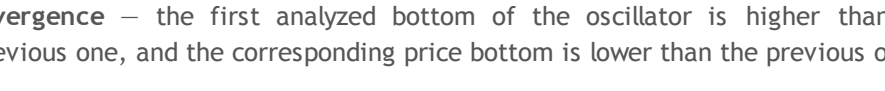

Parameter	Description
Weight	Weight of signal of the module in the interval 0 to 1.
PeriodRVI	Period of calculation of the oscillator.

Signals of the Oscillator Stochastic

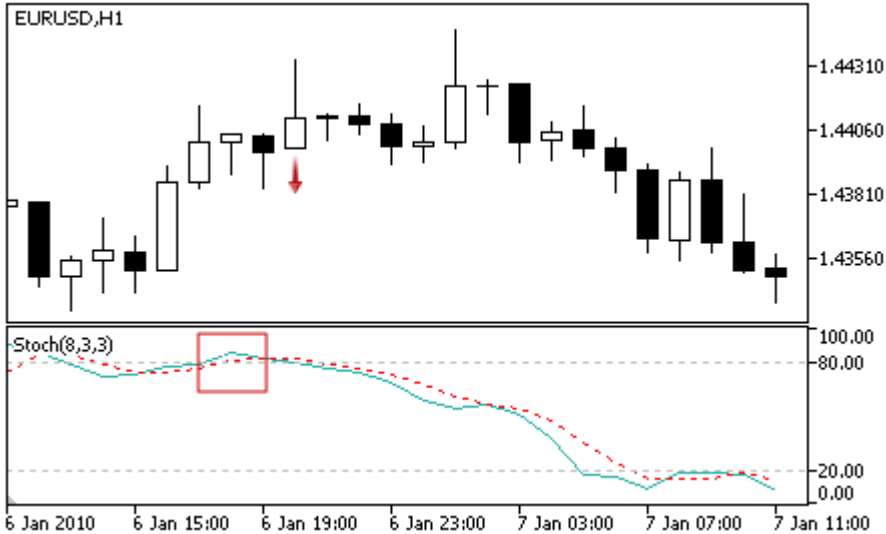

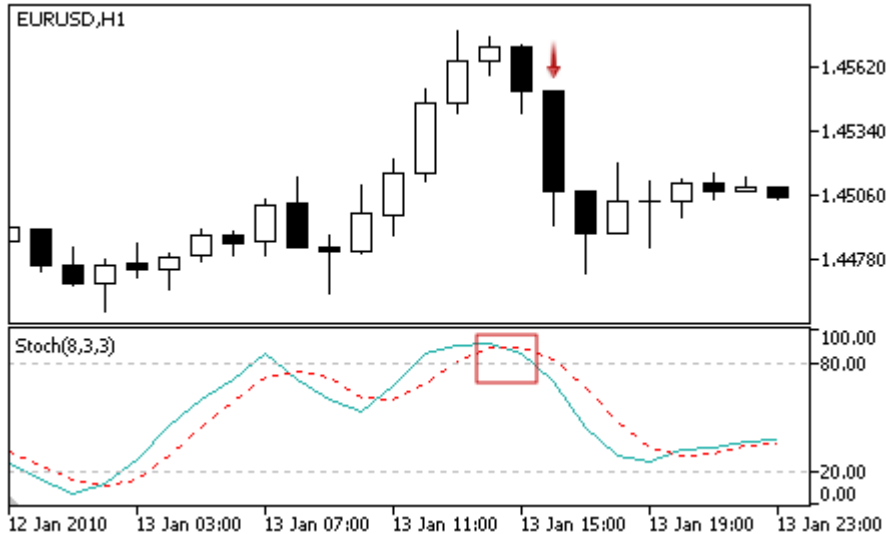

This module of signals is based on the market models of the oscillator [Stochastic](#). The mechanism of making trade decisions based on signals obtained from the modules is described in a [separate section](#).

Conditions of Generation of Signals

Below you can find the description of conditions when the module passes a signal to an Expert Advisor.

Signal Type	Description of Conditions
For buying	<ul style="list-style-type: none"> Reverse – the oscillator turned upwards (the oscillator rises at the analyzed bar and falls at the previous one).  Crossing of the main and signal line – the main line is above the signal line at the analyzed bar and below the signal line at the previous one.  Divergence – the first analyzed bottom of the oscillator is higher than the previous one, and the corresponding price bottom is lower than the previous one. 

Signal Type	Description of Conditions
	<div data-bbox="432 315 1321 846"> <p>EURUSD, H1</p> <p>Stoch(8,3,3)</p> </div> <ul style="list-style-type: none"> • Double divergence – the oscillator form three consequent bottoms, each of them is higher than the previous one; and the price formed three corresponding bottoms, and each of them is lower than the previous one. <div data-bbox="432 992 1321 1525"> <p>EURUSD, H1</p> <p>Stoch(8,3,3)</p> </div>
For selling	<ul style="list-style-type: none"> • Reverse – the oscillator turned downwards (the oscillator falls at the analyzed bar and rises at the previous one).

Signal Type	Description of Conditions
	<div data-bbox="432 315 1321 846">  <p>EURUSD,H1</p> <p>Stoch(8,3,3)</p> </div> <ul style="list-style-type: none"> • Crossing of the main and signal line – the main line is below the signal line at the analyzed bar and above the signal line at the previous one. <div data-bbox="432 958 1321 1489">  <p>EURUSD,H1</p> <p>Stoch(8,3,3)</p> </div> <ul style="list-style-type: none"> • Divergence – the first analyzed peak of the oscillator is lower than the previous one, and the corresponding price peak is higher than the previous peak.

Signal Type	Description of Conditions
	<div data-bbox="432 315 1321 846"> <p>EURUSD,H1</p> <p>Stoch(8,3,3)</p> <p>4 Jan 2010 4 Jan 04:00 4 Jan 08:00 4 Jan 12:00 4 Jan 16:00 4 Jan 20:00 5 Jan 00:00</p> </div> <ul style="list-style-type: none"> • Double divergence – the oscillator formed three consequent peaks, each of them is lower than the previous one; and the price formed three corresponding peaks, each of them is higher than the previous one. <div data-bbox="432 994 1321 1525"> <p>EURUSD,H1</p> <p>Stoch(8,3,3)</p> <p>1 Feb 2010 2 Feb 00:00 2 Feb 04:00 2 Feb 08:00 2 Feb 12:00 2 Feb 16:00 2 Feb 20:00</p> </div>
No objections to buying	Value of the oscillator grows at the analyzed bar.
No objections to selling	Value of the oscillator falls at the analyzed bar.

Note

Depending on the mode of operation of an Expert Advisor ("Every tick" or "Open prices only") an analyzed bar is either the current bar (with index 0), or the last formed bar (with index 1).

Adjustable Parameters

This module has the following adjustable parameters:

Parameter	Description
Weight	Weight of signal of the module in the interval 0 to 1.
PeriodK	Period of calculation of the main line of the oscillator.
PeriodD	Period of averaging of the main line of the oscillator.
PeriodSlow	Period of slowing.
Applied	A price series used for calculation of the oscillator.

Signals of the Oscillator Triple Exponential Average

This module of signals is based on the market models of the oscillator [Triple Exponential Average](#). The mechanism of making trade decisions based on signals obtained from the modules is described in a [separate section](#).

Conditions of Generation of Signals

Below you can find the description of conditions when the module passes a signal to an Expert Advisor.

Signal Type	Description of Conditions
For buying	<ul style="list-style-type: none"> Reverse – the oscillator turned upwards (the oscillator rises at the analyzed bar and falls at the previous one).  Crossing the zero level – the main line is above the zero level at the analyzed bar and below the zero level at the previous one. 

Signal Type	Description of Conditions
	<ul style="list-style-type: none"> • Divergence – the first analyzed bottom of the oscillator is higher than the previous one, and the corresponding price bottom is lower than the previous one. 
For selling	<ul style="list-style-type: none"> • Reverse – the oscillator turned downwards (the oscillator falls at the analyzed bar and rises at the previous one).  <ul style="list-style-type: none"> • Crossing the zero level – the main line is below the zero level at the analyzed bar and above the zero level at the previous one.

Signal Type	Description of Conditions
	 <ul style="list-style-type: none"> • Divergence – the first analyzed peak of the oscillator is lower than the previous one, and the corresponding price peak is higher than the previous peak. 
No objections to buying	Value of the oscillator grows at the analyzed bar.
No objections to selling	Value of the oscillator falls at the analyzed bar.

Note

Depending on the mode of operation of an Expert Advisor ("Every tick" or "Open prices only") an analyzed bar is either the current bar (with index 0), or the last formed bar (with index 1).

Adjustable Parameters

This module has the following adjustable parameters:

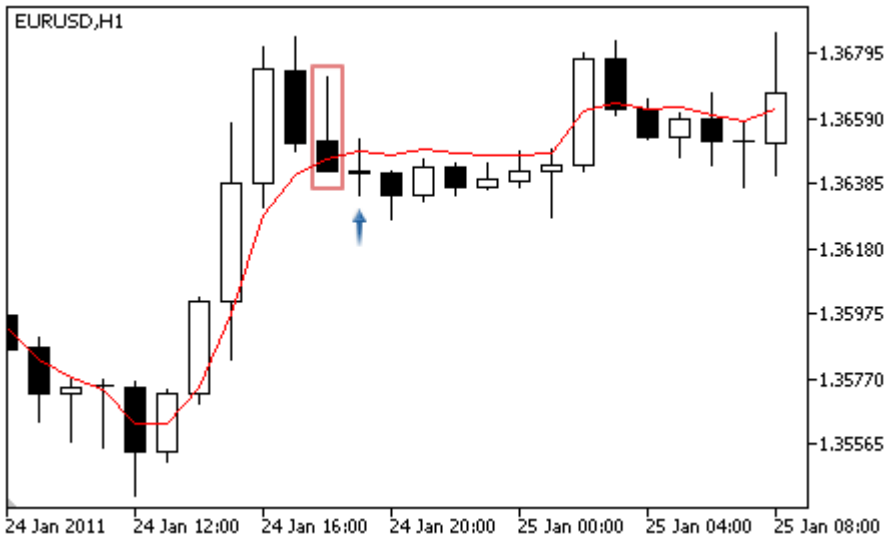

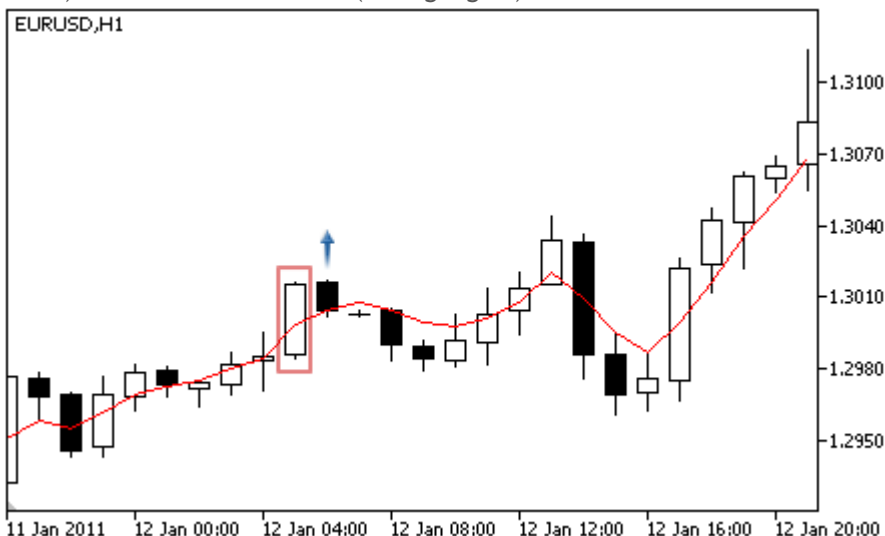

Parameter	Description
Weight	Weight of signal of the module in the interval 0 to 1.
PeriodTriX	Period of calculation of the oscillator.
Applied	A price series used for calculation of the oscillator.

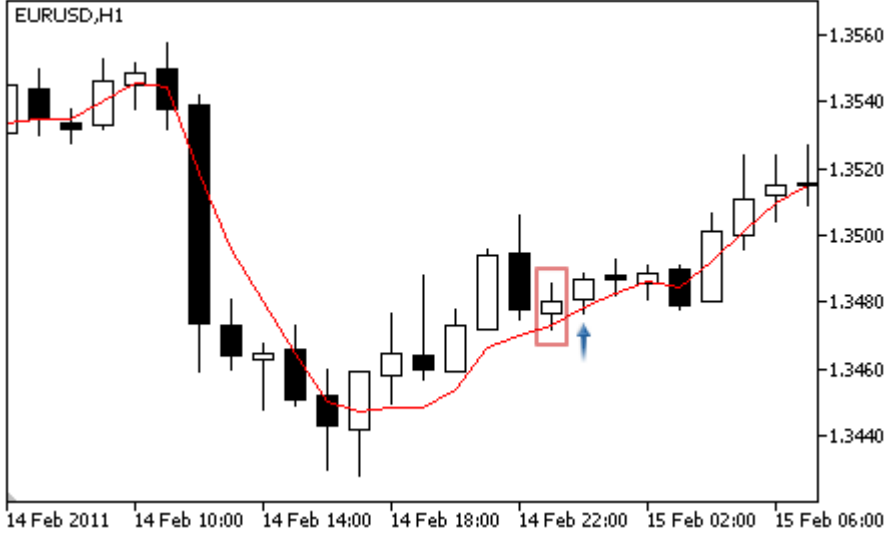

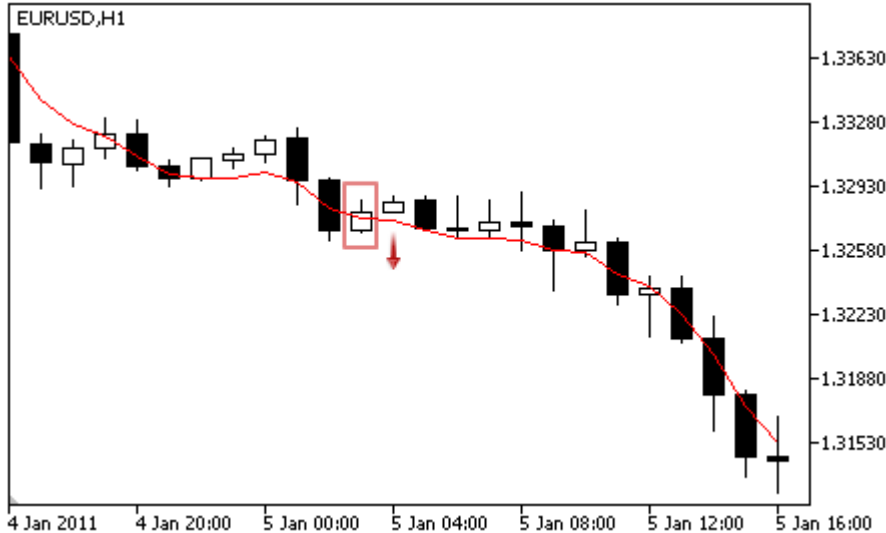

Signals of the Indicator Triple Exponential Moving Average

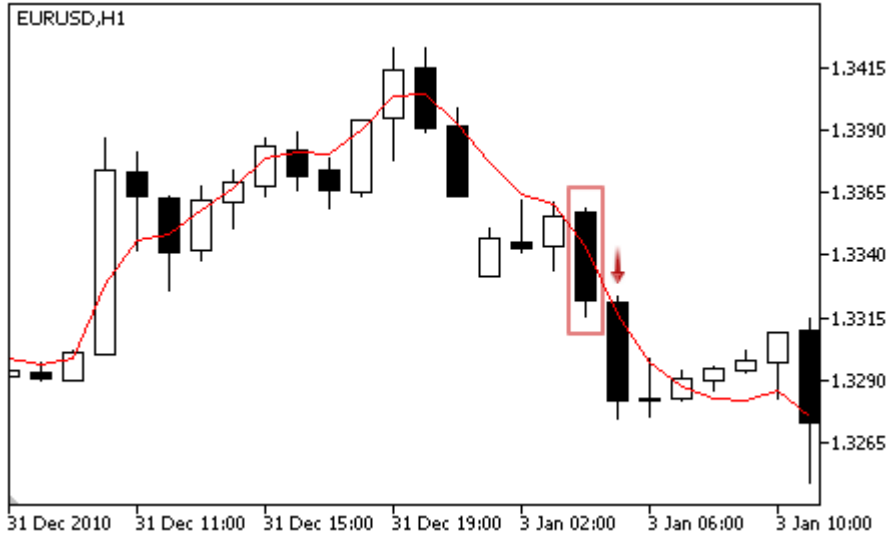

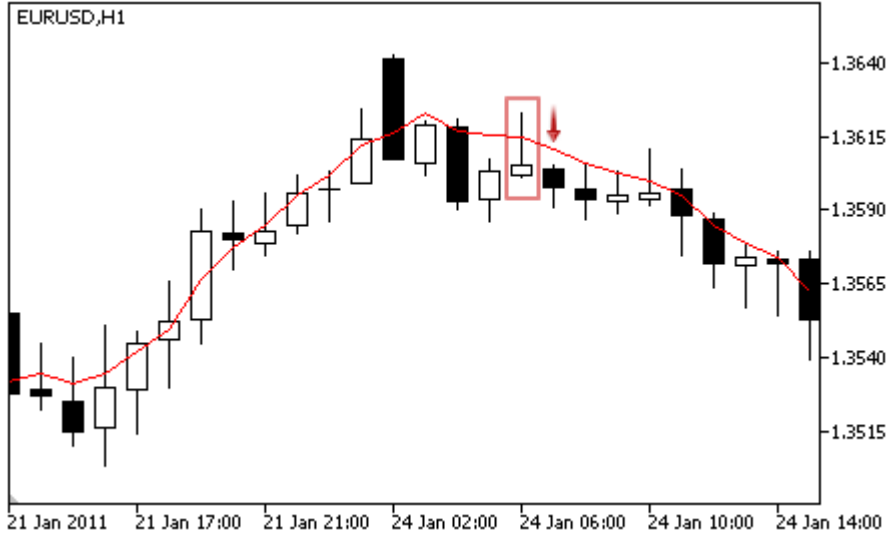

This module of signals is based on the market models of the indicator [Triple Exponential Moving Average](#). The mechanism of making trade decisions based on signals obtained from the modules is described in a [separate section](#).

Conditions of Generation of Signals

Below you can find the description of conditions when the module passes a signal to an Expert Advisor.

Signal Type	Description of Conditions
For buying	<ul style="list-style-type: none"> The price has crossed the indicator downwards (the Open price of the analyzed bar is above the indicator and the Close price is below the indicator) and the indicator rises (weak signal of a roll-back from the indicator line).  <ul style="list-style-type: none"> Moving Average crossover. The price has crossed the indicator upwards (the Open price of the analyzed bar is below the indicator and the Close price is above the indicator) and the indicator rises (strong signal). 

Signal Type	Description of Conditions
	<ul style="list-style-type: none"> • Formed breakout. The lower shadow of the bar has crossed the indicator (the Open and Close prices of the analyzed bar are above the indicator, and the Low price is below the indicator) and the indicator rises (weak signal of a roll-back from the indicator line).  <p>The chart displays EURUSD on an H1 timeframe from 14 Feb 2011 to 15 Feb 2011. A red line indicator is plotted. A candlestick bar on Feb 14 at 22:00 is highlighted with a red box, showing its lower shadow crossing the indicator line. A blue arrow points to the indicator line at approximately 1.3475.</p>
For selling	<ul style="list-style-type: none"> • Failed breakout. The price has crossed the indicator upwards (the Open price of the analyzed bar is below the indicator and the Close price is above the indicator) and the indicator falls (weak signal of a roll-back from the indicator line).  <p>The chart displays EURUSD on an H1 timeframe from 4 Jan 2011 to 5 Jan 2011. A red line indicator is plotted. A candlestick bar on Jan 5 at 00:00 is highlighted with a red box, showing its open price below the indicator and its close price above it. A red arrow points to the indicator line at approximately 1.32580.</p> <ul style="list-style-type: none"> • Moving Average crossover. The price has crossed the indicator downwards (the Open price of the analyzed bar is above the indicator and the Close price is below the indicator) and the indicator falls (strong signal).

Signal Type	Description of Conditions
	 <p>• Formed breakout. The upper shadow of the bar has crossed the indicator (the Open and Close prices of the analyzed bar are below the indicator, and the High price is above the indicator) and the indicator falls (weak signal of a roll-back from the indicator line).</p> 
No objections to buying	The price is above the indicator.
No objections to selling	The price is below the indicator.

Note

Depending on the mode of operation of an Expert Advisor ("Every tick" or "Open prices only") an analyzed bar is either the current bar (with index 0), or the last formed bar (with index 1).

Adjustable Parameters

This module has the following adjustable parameters:

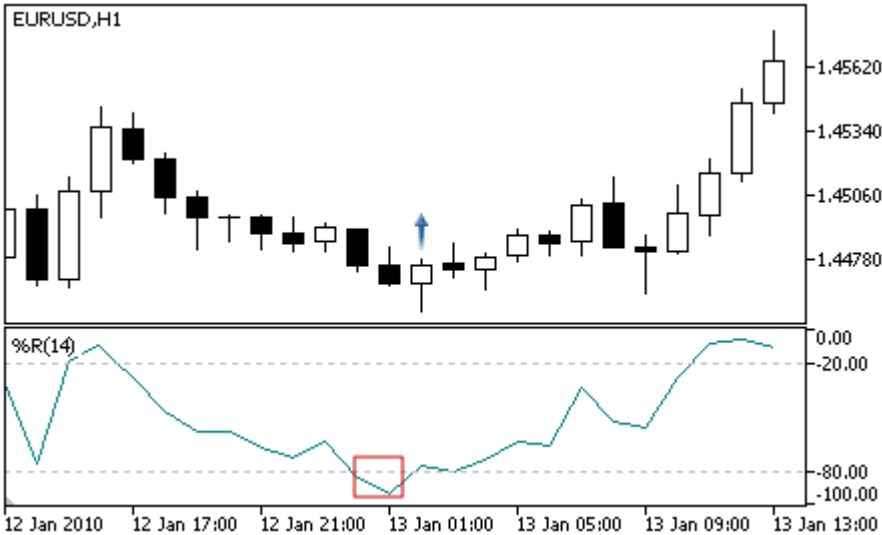

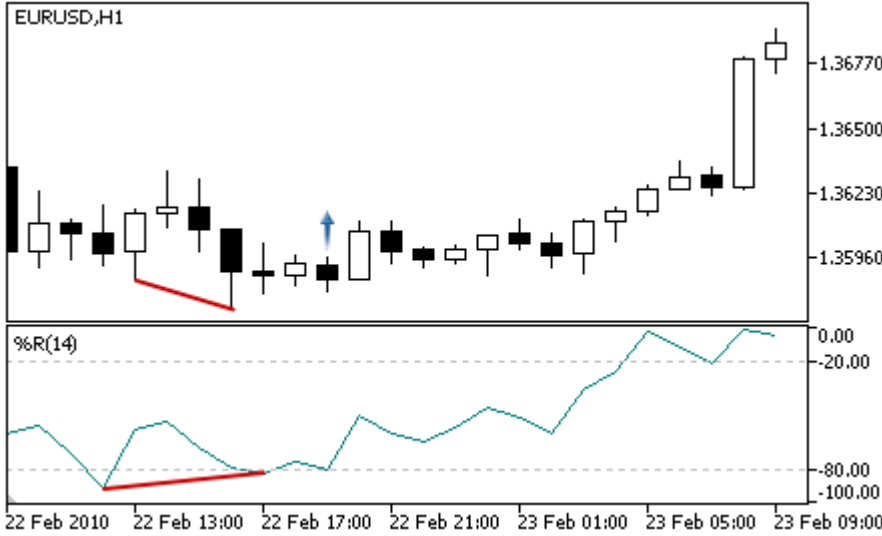

Parameter	Description
Weight	Weight of signal of the module in the interval 0 to 1.
PeriodMA	Period of averaging of the indicator.
Shift	Shift of the indicator along the time axis (in bars).
Method	Method of averaging.
Applied	A price series used for calculation of the indicator.

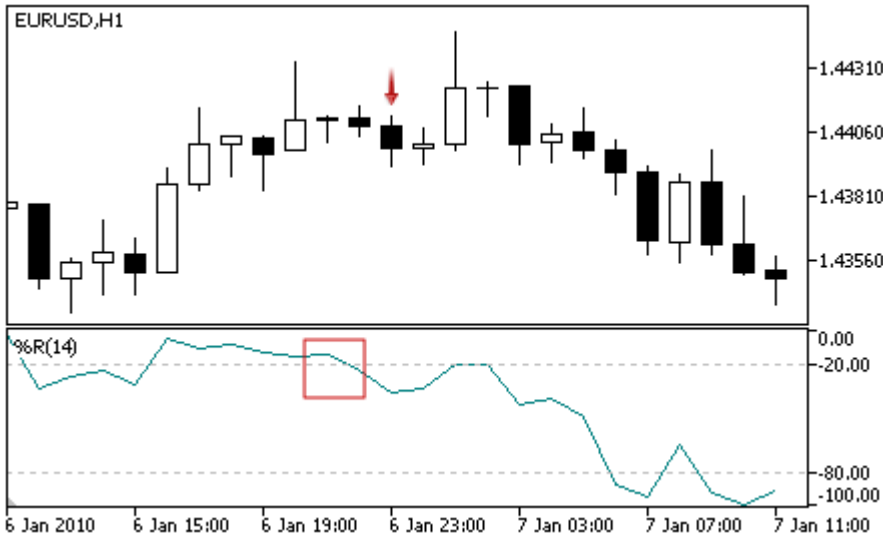

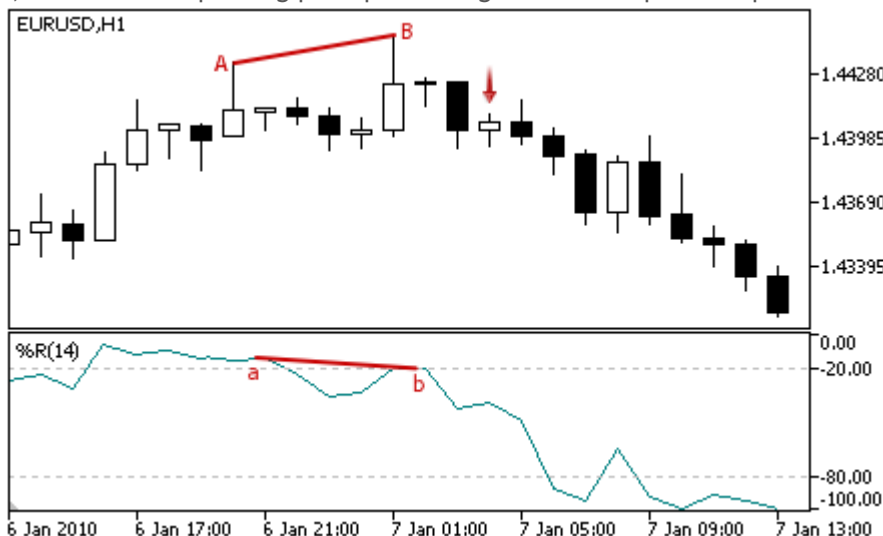

Signals of the Oscillator Williams Percent Range

This module of signals is based on the market models of the oscillator [Williams Percent Range](#). The mechanism of making trade decisions based on signals obtained from the modules is described in a [separate section](#).

Conditions of Generation of Signals

Below you can find the description of conditions when the module passes a signal to an Expert Advisor.

Signal Type	Description of Conditions
For buying	<ul style="list-style-type: none"> Reverse behind the oversold level – the oscillator turned upwards and its value at the analyzed bar is behind the oversold level (default value is -80).  Divergence – the first analyzed bottom of the oscillator is higher than the previous one, and the corresponding price bottom is lower than the previous one. 

Signal Type	Description of Conditions
For selling	<ul style="list-style-type: none"> Reverse behind the overbought level – the oscillator turned downwards and its value at the analyzed bar is behind the overbought level (default value is -20).  <ul style="list-style-type: none"> Divergence – the first analyzed peak of the oscillator is lower than the previous one, and the corresponding price peak is higher than the previous peak. 
No objections to buying	Value of the oscillator grows at the analyzed bar.
No objections to selling	Value of the oscillator falls at the analyzed bar.

Note

Depending on the mode of operation of an Expert Advisor ("Every tick" or "Open prices only") an analyzed bar is either the current bar (with index 0), or the last formed bar (with index 1).

Remember that the oscillator Williams Percent Range has a reversed scale. Its maximum value is -100, and minimum is 0.

Adjustable Parameters

This module has the following adjustable parameters:

Parameter	Description
Weight	Weight of signal of the module in the interval 0 to 1.
PeriodWPR	Period of calculation of the oscillator.

Trailing Stop classes

This section contains technical details of working with trailing stop classes and description of the relevant components of the MQL5 standard library.

The use of these classes will save time when creating (and testing) trading strategies.

MQL5 Standard Library (in terms of trading strategies) is placed in the terminal directory, in the Include\Expert\Trailing folder.

Class	Description
<u>CTrailingFixedPips</u>	This class implements Trailing Stop algorithm based on fixed points
<u>CTrailingMA</u>	This class implements Trailing Stop algorithm based on the values of Moving Average indicator
<u>CTrailingNone</u>	A stub class, it does not uses any Trailing Stop algorithm
<u>CTrailingPSAR</u>	This class implements Trailing Stop algorithm based on the values of Parabolic SAR indicator

CTrailingFixedPips

CTrailingFixedPips is a class with implementation of Trailing Stop algorithm based on fixed points trailing.

CTrailingFixedPips class implements the following algorithm of trailing open positions: If Stop Loss level is equal to zero, Stop Loss order modification condition is considered unfulfilled, therefore there is no suggestion to change a position's Stop Loss. Otherwise, the check of whether the price has moved in favorable direction is performed.

If a position has a Stop Loss order, it checks the minimal allowed Stop Loss distance to the current price. If the position has no Stop Loss level, the distance between the current and open prices is checked. If the distance exceeds Stop Loss level, the system suggests to set a new Stop Loss price.

If Stop Loss modification condition is fulfilled and Take Profit is not equal to zero, the system suggests setting a new Take Profit price.

If Expert Advisor class has been [initialized](#) with the flag every_tick=false, it will perform all operations (trading, trailing, etc) only at the new bar on a working symbol and timeframe. In this case, setting Take Profit order allows you to close position when the price moves in the position direction before a new bar appears.

Description

CTrailingFixedPips implements the Trailing Stop algorithm at a specified "distance" from the current price (in points).

Declaration

```
class CTrailingFixedPips: public CExpertTrailing
```

Title

```
#include <Expert\Trailing\CTrailingFixedPips.mqh>
```

Inheritance hierarchy

Class Methods by Groups

Initialization	
StopLevel	Sets the value of Stop Loss level
ProfitLevel	Sets the value of Take Profit level
virtual ValidationSettings	Checks the settings
Check Trailing Methods	

virtual CheckTrailingStopLong	Check Trailing Stop conditions of a long position
virtual CheckTrailingStopShort	Check Trailing Stop conditions of a short position

Methods inherited from class CObject

Prev, [Prev](#), [Next](#), [Next](#), [Save](#), [Load](#), [Type](#), [Compare](#)

Methods inherited from class CExpertBase

[InitPhase](#), [TrendType](#), [UsedSeries](#), [EveryTick](#), [Open](#), [High](#), [Low](#), [Close](#), [Spread](#), [Time](#), [TickVolume](#), [RealVolume](#), [Init](#), [Symbol](#), [Period](#), [Magic](#), [SetMarginMode](#), [SetPriceSeries](#), [SetOtherSeries](#), [InitIndicators](#)

StopLevel

Sets the value of Stop Loss level.

```
void StopLevel(  
    int stop_level    // level  
)
```

Parameters

stop_loss

[in] The value of Stop Loss level (in conventional 2/4-digit points).

Note

If Stop Loss level is equal to 0, the Trailing Stop is not used.

ProfitLevel

Sets the value of Take Profit level.

```
void ProfitLevel(  
    int profit_level    // level  
)
```

Parameters

profit_level

[in] The value of Take Profit level (in conventional 2/4-digit points).

Note

If profit level is equal to 0, the Trailing Stop is not used.

ValidationSettings

Checks the settings.

```
virtual bool ValidationSettings()
```

Return Value

true - successful, otherwise - false.

Note

The function checks Take Profit and Stop Loss levels. The correct values are 0 and values greater than the minimal indention in points from the current close price to place Stop orders.

CheckTrailingStopLong

Checks Trailing Stop conditions of a long position.

```
virtual bool CheckTrailingStopLong(  
    CPositionInfo* position,    // pointer  
    double& sl,                // reference to Stop Loss  
    double& tp                 // reference to Take Profit  
)
```

Parameters

position

[in] Pointer to [CPositionInfo](#) object.

sl

[in][out] Reference to variable for Stop Loss price.

tp

[in][out] Reference to variable for Take Profit price.

Return Value

true - conditions are satisfied, otherwise - false.

Note

If Stop Loss level is equal to 0, the condition is not fulfilled (exit). If position already has Stop Loss price, its value is assumed as a base price, otherwise the position open price is assumed as a base price. If the current Bid price is higher than base price+stop loss level, it suggests to set new Stop Loss price. In this case, If position already has Take Profit price, it suggests to set new Take Profit price equal to Bid price+take profit level.

CheckTrailingStopShort

Checks Trailing Stop conditions of a short position.

```
virtual bool CheckTrailingStopShort (
    CPositionInfo* position,      // pointer
    double& sl,                  // reference to Stop Loss
    double& tp                    // reference to Take Profit
)
```

Parameters

position

[in] Pointer to [CPositionInfo](#) object.

sl

[in][out] Reference to variable for Stop Loss price.

tp

[in][out] Reference to variable for Take Profit price.

Return Value

true - conditions are satisfied, otherwise - false.

Note

If Stop Loss level is equal to 0, the condition is not fulfilled (exit). If position already has Stop Loss price, its value is assumed as a base price, otherwise the position open price is assumed as a base price. If the current Ask price is lower than base price - stop loss level, it suggests to set new Stop Loss price. In this case, If position already has Take Profit price, it suggests to set new Take Profit price equal to Ask price - take profit level.

CTrailingMA

CTrailingMA is a class with implementation of Trailing Stop algorithm based on the values of moving average indicator.

Description

CTrailingMA class implements Trailing Stop algorithm based on the values of moving average indicator of the previous (completed) bar.

Declaration

```
class CTrailingMA: public CExpertTrailing
```

Title

```
#include <Expert\Trailing\TrailingMA.mqh>
```

Inheritance hierarchy

[CObject](#)

[CExpertBase](#)

[CExpertTrailing](#)

CTrailingMA

Class Methods by Groups

Initialization	
Period	Sets period of moving average
Shift	Sets shift of moving average
Method	Sets smoothing method of moving average
Applied	Sets applied price of moving average
virtual InitIndicators	Initializes indicators and timeseries
virtual ValidationSettings	Checks the settings
Check Trailing Methods	
virtual CheckTrailingStopLong	Check Trailing Stop conditions of a long position
virtual CheckTrailingStopShort	Check Trailing Stop conditions of a short position

Methods inherited from class CObject

Prev, Prev, Next, Next, [Save](#), [Load](#), [Type](#), [Compare](#)

Methods inherited from class CExpertBase

[InitPhase](#), [TrendType](#), [UsedSeries](#), [EveryTick](#), [Open](#), [High](#), [Low](#), [Close](#), [Spread](#), [Time](#), [TickVolume](#),
[RealVolume](#), [Init](#), [Symbol](#), [Period](#), [Magic](#), [SetMarginMode](#), [SetPriceSeries](#), [SetOtherSeries](#)

Period

Sets period of a moving average.

```
void Period(  
    int period    // period  
)
```

Parameters

period

[in] Period of a moving average.

Shift

Sets shift of a moving average.

```
void Shift(  
    int shift    // parameter  
)
```

Parameters

shift

[in] Shift of a moving average.

Method

Sets smoothing method of a moving average.

```
void Method(  
    ENUM_MA_METHOD method      // parameter  
)
```

Parameters

method

[in] Smoothing method (from [ENUM_MA_METHOD](#) enumeration) of a moving average.

Applied

Sets applied price of a moving average.

```
void Applied(  
    ENUM_APPLIED_PRICE applied // parameter  
)
```

Parameters

applied

[in] Applied price (from [ENUM_APPLIED_PRICE](#) enumeration) of a moving average.

InitIndicators

Initializes indicators and timeseries.

```
virtual bool InitIndicators(  
    CIndicators* indicators // pointer  
)
```

Parameters

indicators

[in] Pointer to indicators and timeseries collection ([CExpert](#) class member).

Return Value

true - successful, otherwise - false.

ValidationSettings

Checks the settings.

```
virtual bool ValidationSettings()
```

Return Value

true - successful, otherwise - false.

Note

The function checks the period of moving average, the correct values are positive.

CheckTrailingStopLong

Checks Trailing Stop conditions of a long position.

```
virtual bool CheckTrailingStopLong(  
    CPositionInfo* position,    // pointer  
    double& sl,                // reference  
    double& tp                 // reference  
)
```

Parameters

position

[in] Pointer to [CPositionInfo](#) object.

sl

[in][out] Reference to variable for Stop Loss price.

tp

[in][out] Reference to variable for Take Profit price.

Return Value

true - conditions are satisfied, otherwise - false.

Note

First it calculates the maximal allowed Stop Loss price closest to the current price and calculates Stop Loss price using the values of moving average indicator of the previous (completed) bar. If position already has Stop Loss price, its value is assumed as a base price, otherwise the base price is the open price of the position. If the calculated Stop Loss price is higher than base price and lower than maximal allowed Stop Loss price, it suggests to set new Stop Loss price.

CheckTrailingStopShort

Checks Trailing Stop conditions of a short position.

```
virtual bool CheckTrailingStopShort (
    CPositionInfo* position,    // pointer
    double& sl,                // reference
    double& tp                 // reference
)
```

Parameters

position

[in] Pointer to [CPositionInfo](#) object.

sl

[in][out] Reference to variable for Stop Loss price.

tp

[in][out] Reference to variable for Take Profit price.

Return Value

true - conditions are satisfied, otherwise - false.

Note

First it calculates the minimal allowed Stop Loss price closest to the current price and calculates Stop Loss price using the values of moving average indicator of the previous (completed) bar. If position already has Stop Loss price, its value is assumed as a base price, otherwise the base price is the open price of the position. If the calculated Stop Loss price is lower than base price and higher than minimal allowed Stop Loss price, it suggests to set new Stop Loss price.

CTrailingNone

CTrailingNone is a stub class. This class should be used at initialization of trailing object in CExpert class if your strategy does not use Trailing Stop.

Description

CTrailingNone class does not implement any Trailing Stop algorithm. The methods of checking Trailing Stop conditions always return false.

Declaration

```
class CTrailingNone: public CExpertTrailing
```

Title

```
#include <Expert\Trailing\TrailingNone.mqh>
```

[CheckTrailingStopLong](#), [CheckTrailingStopShort](#)

CheckTrailingStopLong

Checks Trailing Stop conditions of a long position.

```
virtual bool CheckTrailingStopLong(  
    CPositionInfo* position,    // pointer  
    double& sl,                // reference  
    double& tp                 // reference  
)
```

Parameters

position

[in] Pointer to [CPositionInfo](#) object.

sl

[in][out] Reference to variable for Stop Loss price.

tp

[in][out] Reference to variable for Take Profit price.

Return Value

true - conditions are satisfied, otherwise - false.

Note

The function always returns false.

CheckTrailingStopShort

Checks Trailing Stop conditions of a short position.

```
virtual bool CheckTrailingStopShort (
    CPositionInfo* position,    // pointer
    double& sl,                // reference
    double& tp                 // reference
)
```

Parameters

position

[in] Pointer to [CPositionInfo](#) object.

sl

[in][out] Reference to variable for Stop Loss price.

tp

[in][out] Reference to variable for Take Profit price.

Return Value

true - conditions are satisfied, otherwise - false.

Note

The function always returns false.

CTrailingPSAR

CTrailingPSAR is a class with implementation of Trailing Stop algorithm based on the values of Parabolic SAR indicator.

Description

CTrailingPSAR class implements the Trailing Stop algorithm based on the values of Parabolic SAR indicator of the previous (completed) bar.

Declaration

```
class CTrailingPSAR: public CExpertTrailing
```

Title

```
#include <Expert\Trailing\TrailingParabolicSAR.mqh>
```

Inheritance hierarchy

[CObject](#)

[CExpertBase](#)

[CExpertTrailing](#)

CTrailingPSAR

Class Methods by Groups

Initialization	
Step	Sets the value of step of Parabolic SAR indicator
Maximum	Sets the value of maximum of Parabolic SAR indicator
virtual InitIndicators	Initializes indicators and timeseries
Check Trailing Methods	
virtual CheckTrailingStopLong	Check conditions of trailing stop of a long position
virtual CheckTrailingStopShort	Check conditions of trailing stop of a short position

Methods inherited from class CObject

Prev, Prev, Next, Next, [Save](#), [Load](#), [Type](#), [Compare](#)

Methods inherited from class CExpertBase

[InitPhase](#), [TrendType](#), [UsedSeries](#), [EveryTick](#), [Open](#), [High](#), [Low](#), [Close](#), [Spread](#), [Time](#), [TickVolume](#), [RealVolume](#), [Init](#), [Symbol](#), [Period](#), [Magic](#), [SetMarginMode](#), [ValidationSettings](#), [SetPriceSeries](#), [SetOtherSeries](#)

Step

Sets the value of step of Parabolic SAR indicator.

```
void Step(  
    double step    // parameter  
)
```

Parameters

step

[in] The value of step of Parabolic SAR indicator.

Maximum

Sets the value of maximum of Parabolic SAR indicator.

```
void Maximum(  
    double maximum    // parameter  
)
```

Parameters

maximum

[in] The value of maximum of Parabolic SAR indicator.

InitIndicators

Initializes indicators and timeseries.

```
virtual bool InitIndicators(  
    CIndicators* indicators // pointer  
)
```

Parameters

indicators

[in] Pointer to indicators and timeseries collection ([CExpert](#) class member).

Return Value

true - successful, otherwise - false.

CheckTrailingStopLong

Checks Trailing Stop conditions of a long position.

```
virtual bool CheckTrailingStopLong(  
    CPositionInfo* position,    // pointer  
    double& sl,                // reference  
    double& tp                 // reference  
)
```

Parameters

position

[in] Pointer to [CPositionInfo](#) object.

sl

[in][out] Reference to variable for Stop Loss price.

tp

[in][out] Reference to variable for Take Profit price.

Return Value

true - conditions are satisfied, otherwise - false.

Note

First it calculates the maximal allowed Stop Loss price closest to the current price and calculates Stop Loss price using the values of Parabolic SAR indicator of the previous (completed) bar. If position already has Stop Loss price, its value is assumed as a base price, otherwise the position open price is assumed as a base price. If the calculated Stop Loss price is higher than base price and lower than maximal allowed Stop Loss price, it suggests to set new Stop Loss price.

CheckTrailingStopShort

Checks Trailing Stop conditions of a short position.

```
virtual bool CheckTrailingStopShort (
    CPositionInfo* position,    // pointer
    double& sl,                // reference
    double& tp                 // reference
)
```

Parameters

position

[in] Pointer to [CPositionInfo](#) object.

sl

[in][out] Reference to variable for Stop Loss price.

tp

[in][out] Reference to variable for Take Profit price.

Return Value

true - conditions are satisfied, otherwise - false.

Note

First it calculates the minimal allowed Stop Loss price closest to the current price and calculates Stop Loss price using the values of Parabolic SAR indicator of the previous (completed) bar. If position already has Stop Loss price, its value is assumed as a base price, otherwise the position open price is assumed as a base price. If the calculated Stop Loss price is lower than base price and higher than minimal allowed Stop Loss price, it suggests to set new Stop Loss price.

Money Management classes

This section contains technical details of working with money and risk management classes and description of the relevant components of the MQL5 standard library.

The use of these classes will save time when creating (and testing) trading strategies.

MQL5 Standard Library (in terms of money and risk management classes) is placed in the terminal directory, in the Include\Expert\Money\ folder.

Class	Description
<u>CMoneyFixedLot</u>	This class implements money management algorithm based on trading with predefined fixed lot size.
<u>CMoneyFixedMargin</u>	This class implements money management algorithm based on trading with predefined fixed margin.
<u>CMoneyFixedRisk</u>	This class implements money management algorithm based on trading with predefined risk.
<u>CMoneyNone</u>	This class implements money management algorithm based on trading with minimal allowed lot size.
<u>CMoneySizeOptimized</u>	This class implements money management algorithm based on trading with variable lot size, depending on results of the previous deals.

CMoneyFixedLot

CMoneyFixedLot is the class designed to implement money management algorithm based on trading with predefined fixed lot size.

Description

CMoneyFixedLot implements money management algorithm based on trading with predefined fixed lot size.

Declaration

```
class CMoneyFixedLot: public CExpertMoney
```

Title

```
#include <Expert\Money\MoneyFixedLot.mqh>
```

Inheritance hierarchy

Class Methods by Groups

Initialization	
Lots	Sets trading volume
virtual ValidationSettings	Checks the settings
Money and Risk Management Methods	
virtual CheckOpenLong	Gets trade volume for a long position
virtual CheckOpenShort	Gets trade volume for a short position

Methods inherited from class CObject

Prev, Prev, Next, Next, [Save](#), [Load](#), [Type](#), [Compare](#)

Methods inherited from class CExpertBase

[InitPhase](#), [TrendType](#), [UsedSeries](#), [EveryTick](#), [Open](#), [High](#), [Low](#), [Close](#), [Spread](#), [Time](#), [TickVolume](#), [RealVolume](#), [Init](#), [Symbol](#), [Period](#), [Magic](#), [SetMarginMode](#), [SetPriceSeries](#), [SetOtherSeries](#), [InitIndicators](#)

Methods inherited from class CExpertMoney

[Percent](#), [CheckReverse](#), [CheckClose](#)

Lots

Sets trading volume (in lots).

```
void Lots(  
    double lots    // number of lots  
)
```

Parameters

lots

[in] Trading volume.

ValidationSettings

Checks the settings.

```
virtual bool ValidationSettings()
```

Return Value

true - successful, otherwise - false.

Note

Checks if the predefined fixed lot falls within the range of allowed values and is multiple of change step.

CheckOpenLong

Gets trade volume for a long position.

```
virtual double CheckOpenLong(  
    double price,      // price  
    double sl          // Stop Loss price  
)
```

Parameters

price

[in] Estimated open price.

sl

[in] Estimated Stop Loss order price.

Return Value

Trade volume for a long position.

Note

The function always returns the predefined fixed trade volume.

CheckOpenShort

Gets trade volume for a short position.

```
virtual double CheckOpenShort(  
    double price,      // price  
    double sl          // Stop Loss price  
)
```

Parameters

price

[in] Estimated open price.

sl

[in] Estimated Stop Loss order price.

Return Value

Trade volume for a short position.

Note

The function always returns the predefined fixed trade volume.

CMoneyFixedMargin

CMoneyFixedMargin is the class designed to implement money management algorithm based on trading with predefined fixed margin.

Description

CMoneyFixedMargin implements money management algorithm based on trading with predefined fixed margin.

Declaration

```
class CMoneyFixedMargin: public CExpertMoney
```

Title

```
#include <Expert\Money\MoneyFixedMargin.mqh>
```

Inheritance hierarchy

CheckOpenLong

Gets trade volume for a long position.

```
virtual double CheckOpenLong(  
    double price,      // price  
    double sl          // Stop Loss price  
)
```

Parameters

price

[in] Estimated open price.

sl

[in] Estimated Stop Loss price.

Return Value

Trade volume for a long position.

Note

The function returns trade volume for a long position with a fixed predefined margin. The margin is defined by Percent parameter of [CExpertMoney](#) base class.

CheckOpenShort

Gets trade volume for a short position.

```
virtual double CheckOpenShort(  
    double price,      // price  
    double sl          // Stop Loss price  
)
```

Parameters

price

[in] Estimated open price.

sl

[in] Estimated Stop Loss price.

Return Value

Trade volume for a short position.

Note

The function returns trade volume for a short position with a predefined fixed margin. The margin is defined by Percent parameter of [CExpertMoney](#) base class.

CMoneyFixedRisk

CMoneyFixedRisk is a class with implementation of money management algorithm with fixed predefined risk.

Description

CMoneyFixedRisk class implements the money management algorithm with fixed predefined risk.

Declaration

```
class CMoneyFixedRisk: public CExpertMoney
```

Title

```
#include <Expert\Money\MoneyFixedRisk.mqh>
```

CheckOpenLong

Gets trade volume for a long position.

```
virtual double CheckOpenLong(  
    double price,      // price  
    double sl          // Stop Loss price  
)
```

Parameters

price

[in] Estimated open price.

sl

[in] Estimated Stop Loss price.

Return Value

Trade volume for a long position.

Note

The function returns trade volume for a long position with a fixed predefined risk level. The risk is defined by Percent parameter of [CExpertMoney](#) base class.

CheckOpenShort

Gets trade volume for a short position.

```
virtual double CheckOpenShort(  
    double price,      // price  
    double sl          // Stop Loss price  
)
```

Parameters

price

[in] Estimated open price.

sl

[in] Estimated Stop Loss price.

Return Value

Trade volume for a short position.

Note

The function returns trade volume for a short position with a fixed predefined risk level. The risk is defined by Percent parameter of [CExpertMoney](#) base class.

CMoneyNone

CMoneyNone is a class with implementation of the "absence" of money and risk management.

Description

CMoneyNone class implements trading with minimal allowed lot.

Declaration

```
class CMoneyNone: public CExpertMoney
```

Title

```
#include <Expert\Money\MoneyNone.mqh>
```

Methods inherited from class CExpertMoney

[Percent](#), [CheckReverse](#), [CheckClose](#)

ValidationSettings

Checks the settings.

```
virtual bool ValidationSettings()
```

Return Value

true - successful, otherwise - false.

Note

The function always returns true.

CheckOpenLong

Gets trade volume for a long position.

```
virtual double CheckOpenLong(  
    double price,      // price  
    double sl          // Stop Loss price  
)
```

Parameters

price

[in] Estimated open price.

sl

[in] Estimated Stop Loss price.

Return Value

Trade volume for a long position.

Note

The function always returns the minimal lot size.

CheckOpenShort

Gets trade volume for a short position.

```
virtual double CheckOpenShort(  
    double price,      // price  
    double sl          // Stop Loss price  
)
```

Parameters

price

[in] Estimated open price.

sl

[in] Estimated Stop Loss price.

Return Value

Trade volume for a short position.

Note

The function always returns the minimal lot size.

CMoneySizeOptimized

CMoneySizeOptimized is a class with implementation of money and risk management algorithm depending on results of the previous deals.

Description

CMoneySizeOptimized implements the market entry algorithm with the lot size depending on results of the previous deals.

Declaration

```
class CMoneySizeOptimized: public CExpertMoney
```

Title

```
#include <Expert\Money\MoneySizeOptimized.mqh>
```

Inheritance hierarchy

[CObject](#)

[CExpertBase](#)

Class Methods by Groups

Initialization	
DecreaseFactor	Sets the parameter value
virtual ValidationSettings	Checks the settings
Money and Risk Management Methods	
virtual CheckOpenLong	Gets trade volume for a long position
virtual CheckOpenShort	Gets trade volume for a short position

Methods inherited from class CObject

Prev, Prev, Next, Next, [Save](#), [Load](#), [Type](#), [Compare](#)

Methods inherited from class CExpertBase

[InitPhase](#), [TrendType](#), [UsedSeries](#), [EveryTick](#), [Open](#), [High](#), [Low](#), [Close](#), [Spread](#), [Time](#), [TickVolume](#), [RealVolume](#), [Init](#), [Symbol](#), [Period](#), [Magic](#), [SetMarginMode](#), [SetPriceSeries](#), [SetOtherSeries](#), [InitIndicators](#)

Methods inherited from class CExpertMoney

[Percent](#), [CheckReverse](#), [CheckClose](#)

DecreaseFactor

Sets the value of decrease factor.

```
void DecreaseFactor(  
    double decrease_factor    // decrease factor  
)
```

Parameters

decrease_factor

[in] Decrease factor.

Note

The DecreaseFactor defines the open position volume decreasing coefficient (compared with the volume of a previous position) for the case of consecutive loss trades.

ValidationSettings

Checks the settings.

```
virtual bool ValidationSettings()
```

Return Value

true - successful, otherwise - false.

Note

If the value of decrease factor is negative, it returns false, otherwise it returns true.

CheckOpenLong

Gets trade volume for a long position.

```
virtual double CheckOpenLong(  
    double price,      // price  
    double sl          // Stop Loss price  
)
```

Parameters

price

[in] Estimated open price.

sl

[in] Estimated Stop Loss price.

Return Value

Trade volume for long position.

Note

The function returns trade volume for a long position considering results of previous deals.

CheckOpenShort

Gets trade volume for a short position.

```
virtual double CheckOpenShort(  
    double price,      // price  
    double sl          // Stop Loss price  
)
```

Parameters

price

[in] Estimated open price.

sl

[in] Estimated Stop Loss price.

Return Value

Trade volume for a long position.

Note

The function returns trade volume for a short position considering results of previous deals.

Classes for Creating Control Panels and Dialogs

This section contains technical details of working with classes for creation of controls panels and dialogs, as well as description of the relevant components of the MQL5 standard library.

The use of these classes will save time when developing custom interactive MQL5 applications, including Expert Advisors and indicators.

MQL5 Standard Library (in terms of classes for creation of control panels and dialogs) is placed in the terminal data folder, in the MQL5\Include\Controls.

The sample Expert Advisor, which illustrates the operation of these classes, can be found in MQL5\Expert\Examples\Controls.

Auxiliary structures	Description
<u>CRect</u>	Structure of the rectangular area
<u>CDateTime</u>	Structure for working with date and time

Base classes	Description
<u>CWnd</u>	Base class for all controls
<u>CWndObj</u>	Base class for controls and dialogs
<u>CWndContainer</u>	Base class for complex controls

Simple controls	Description
<u>CLabel</u>	Control, based on "Text label" graphic object
<u>CBmpButton</u>	Control, based on "Bitmap label" graphic object
<u>CButton</u>	Control, based on "Button" graphic object
<u>CEdit</u>	Control, based on "Edit field" graphic object
<u>CPanel</u>	Control, based on "Rectangle label"
<u>CPicture</u>	Control, based on "Bitmap label"

Complex controls	Description
<u>CScroll</u>	Base class of the scroll bar
<u>CScrollV</u>	Vertical scroll bar
<u>CScrollH</u>	Horizontal scroll bar
<u>CWndClient</u>	Base class of the client area with scroll bars
<u>CListView</u>	List view
<u>CComboBox</u>	Combo box

<u>CCheckBox</u>	Check box
<u>CCheckGroup</u>	Check group
<u>CRadioButton</u>	Radio button
<u>CRadioGroup</u>	Radio group
<u>CSpinEdit</u>	Increment/decrement field
<u>CDialog</u>	Dialog
<u>CAppDialog</u>	Main dialog of MQL5 application

CRect

CRect is a class of the rectangular area of the chart.

Description

CRect is a class of the area, it is defined by both coordinates of the upper-left and lower-right corners of a rectangle in Cartesian coordinates.

Declaration

```
class CRect
```

Title

```
#include <Controls\Rect.mqh>
```

Class Methods by Groups

Properties	
<u>Left</u>	Gets/sets the X coordinate of the upper-left corner
<u>Top</u>	Gets/sets the Y coordinate of the upper-left corner
<u>Right</u>	Gets/sets the X coordinate of the lower-right corner
<u>Bottom</u>	Gets/sets the Y coordinate of the lower-right corner
<u>Width</u>	Gets/sets the width
<u>Height</u>	Gets/sets the height
<u>SetBound</u>	Sets new coordinates of the area
<u>Move</u>	Performs the absolute displacement of the area coordinates
<u>Shift</u>	Performs the relative displacement (shift) of the area coordinates
<u>Contains</u>	Checks if the point is inside the area
Additional methods	
<u>Format</u>	Gets the area coordinates as a string

Left (Get Method)

Gets the X coordinate of the upper-left corner.

```
int Left()
```

Return Value

X coordinate of the upper-left corner.

Left (Set Method)

Sets the X coordinate of the upper-left corner.

```
void Left(  
    const int x    // x coordinate  
)
```

Parameters

x

[in] New X coordinate of the upper-left corner.

Return Value

None.

Top (Get Method)

Gets the Y coordinate of the upper-left corner.

```
int Top()
```

Return Value

Y coordinate of the upper-left corner.

Top (Set Method)

Sets the Y coordinate of the upper-left corner.

```
void Top(  
    const int y    // y coordinate  
)
```

Parameters

y

[in] New Y coordinate of the upper-left corner.

Return Value

None.

Right (Get Method)

Gets the X coordinate of the lower-right corner.

```
int Right()
```

Return Value

X coordinate of the lower-right corner.

Right (Set Method)

Sets the X coordinate of the lower-right corner.

```
void Right(  
    const int x    // x coordinate  
)
```

Parameters

x

[in] New X coordinate of the lower-right corner.

Return Value

None.

Bottom (Get Method)

Gets the Y coordinate of the lower-right corner.

```
int Bottom()
```

Return Value

Y coordinate of the lower-right corner.

Bottom (Set Method)

Sets the Y coordinate of the lower-right corner.

```
void Bottom(  
    const int y    // y coordinate  
)
```

Parameters

y

[in] New Y coordinate of the lower-right corner.

Return Value

None.

Width (Get Method)

Gets the width of the area.

```
int Width()
```

Return Value

Width of the area.

Width (Set Method)

Sets new width of the area.

```
virtual bool Width(  
    const int w    // width  
)
```

Parameters

w

[in] New width.

Return Value

true - successful, otherwise - false.

Height (Get Method)

Gets the height of the area.

```
int Height()
```

Return Value

Height of the area.

Height (Set Method)

Sets new height of the area.

```
virtual bool Height(  
    const int h    // height  
)
```

Parameters

h

[in] New height.

Return Value

true - successful, otherwise - false.

SetBound

Sets new coordinates of the area using CRect class coordinates.

```
void SetBound(  
    const & CRect rect    // CRect class  
)
```

Return Value

None.

SetBound

Sets new coordinates of the area.

```
void SetBound(  
    const int l    // left  
    const int t    // top  
    const int r    // right  
    const int b    // bottom  
)
```

Parameters

l

[in] X coordinate of the upper-left corner.

t

[in] Y coordinate of the upper-left corner.

r

[in] X coordinate of the lower-right corner.

b

[in] Y coordinate of the lower-right corner.

Return Value

None.

Move

Performs the absolute displacement of the area coordinates.

```
void Move(  
    const int x,      // X coordinate  
    const int y      // Y coordinate  
)
```

Parameters

x

[in] New X coordinate.

y

[in] New Y coordinate.

Return Value

None.

Shift

Performs the relative displacement (shift) of the area coordinates.

```
void Shift(  
    const int dx,      // delta X  
    const int dy      // delta Y  
)
```

Parameters

dx

[in] Delta X.

dy

[in] Delta Y.

Return Value

None.

Contains

Checks if the point is inside the CRect class area.

```
bool Contains(  
    const int x,      // X coordinate  
    const int y      // Y coordinate  
)
```

Parameters

x

[in] X coordinate.

y

[in] Y coordinate.

Return Value

true - the point is inside the area (including borders), otherwise - false.

Format

Gets the area coordinates as a string.

```
string Format(  
    string & fmt,      // format  
    ) const
```

Parameters

fmt

[in] String with format.

Return Value

String with the area coordinates.

CDateTime

CDateTime is a structure for working with date and time.

Description

CDateTime is a structure derived from [MqlDateTime](#), it used for operation with date and time in controls.

Declaration

```
struct CDateTime
```

Title

```
#include <Tools\DateTime.mqh>
```

Methods

Properties	
MonthName	Gets month name
ShortMonthName	Gets short name of the month
DayName	Gets full name of the day in a week
ShortDayName	Gets short name of the day in a week
DaysInMonth	Gets number of days in month
Get/Set methods	
DateTime	Gets/sets date and time
Date	Sets date
Time	Sets time
Sec	Sets seconds
Min	Sets minutes
Hour	Sets hour
Day	Sets day of the month
Mon	Sets month
Year	Sets year
Additional methods	
SecDec	Subtracts specified number of seconds
SecInc	Adds specified number of seconds
MinDec	Subtracts specified number of minutes

<u>MinInc</u>	Adds specified number of minutes
<u>HourDec</u>	Subtracts specified number of hours
<u>HourInc</u>	Adds specified number of hours
<u>DayDec</u>	Subtracts specified number of days
<u>DayInc</u>	Adds specified number of days
<u>MonDec</u>	Subtracts specified number of months
<u>MonInc</u>	Adds specified number of months
<u>YearDec</u>	Subtracts specified number of years
<u>YearInc</u>	Adds specified number of years

MonthName

Gets month name.

```
string MonthName() const
```

Gets month name by index.

```
string MonthName(  
    const int    num        // month index  
) const
```

Parameters

num

[in] Month index (1-12).

Return Value

Full month name.

ShortMonthName

Gets short month name.

```
string ShortMonthName() const
```

Gets short month name by index.

```
string ShortMonthName(  
    const int    num        // month index  
) const
```

Parameters

num

[in] Month index (1-12).

Return Value

Short month name.

DayName

Gets full name of the day in a week.

```
string DayName() const
```

Gets full name of the day in a week by index.

```
string DayName (
    const int    num          // day index
) const
```

Parameters

num

[in] Day index (0-6).

Return Value

Full name of the day.

ShortDayName

Gets short name of the day in a week.

```
string ShortDayName() const
```

Gets short name of the day in a week by index.

```
string ShortDayName(  
    const int    num        // day index  
) const
```

Parameters

num

[in] Day index (0-6).

Return Value

Short name of the day.

DaysInMonth

Gets number of days in month.

```
int DaysInMonth() const
```

Return Value

Number of days in month.

DateTime (Get Method)

Gets date and time.

```
datetime DateTime()
```

Return Value

Value of [datetime](#) type.

DateTime (Set Method datetime)

Sets date and time with [datetime](#) type.

```
void DateTime(  
    const datetime    value    // date and time  
)
```

Parameters

value

[in] Value of [datetime](#) type.

Return Value

None.

DateTime (Set Method MqlDateTime)

Sets date and time with [MqlDateTime](#) type.

```
void DateTime(  
    const MqlDateTime &value    // date and time  
)
```

Parameters

value

[in] Value of [MqlDateTime](#) type.

Return Value

None.

Date (Set Method datetime)

Sets date with [datetime](#) type.

```
void Date(  
    const datetime    value    // date  
)
```

Parameters

value

[in] Value of [datetime](#) type.

Return Value

None.

Date (Set Method MqlDateTime)

Sets date with [MqlDateTime](#) type.

```
void Date(  
    const MqlDateTime &value    // date  
)
```

Parameters

value

[in] Value of [MqlDateTime](#) type.

Return Value

None.

Time (Set Method datetime)

Sets time with [datetime](#) type.

```
void Time(  
    const datetime    value    // time  
)
```

Parameters

value

[in] Value of [datetime](#) type.

Return Value

None.

Time (Set Method MqlDateTime)

Sets time with [MqlDateTime](#) type.

```
void Time(  
    const MqlDateTime &value    // time  
)
```

Parameters

value

[in] Value of [MqlDateTime](#) type.

Return Value

None.

Sec

Sets seconds.

```
void Sec(  
    const int value // seconds  
)
```

Parameters

value

[in] Seconds.

Return Value

None.

Min

Sets minutes.

```
void Min(  
    const int  value      // minutes  
)
```

Parameters

value

[in] Minutes.

Return Value

None.

Hour

Sets hour.

```
void Hour(  
    const int  value      // hour  
)
```

Parameters

value

[in] Hour.

Return Value

None.

Day

Sets day of the month.

```
void Day(  
    const int value // day of month  
)
```

Parameters

value

[in] Day of month.

Return Value

None.

Mon

Sets month.

```
void Day(  
    const int  value      // month  
)
```

Parameters

value

[in] Month.

Return Value

None.

Year

Sets year.

```
void Day(  
    const int  value      // year  
)
```

Parameters

value

[in] Year.

Return Value

None.

SecDec

Subtracts specified number of seconds.

```
void SecDec(  
    int    delta=1      // seconds  
)
```

Parameters

delta

[in] Seconds to subtract.

Return Value

None.

SecInc

Adds specified number of seconds.

```
void SecInc(  
    int    delta=1    // seconds  
)
```

Parameters

delta

[in] Seconds to add.

Return Value

None.

MinDec

Subtracts specified number of minutes.

```
void MinDec(  
    int    delta=1        // minutes  
)
```

Parameters

delta

[in] Minutes to subtract.

Return Value

None.

MinInc

Adds specified number of minutes.

```
void MinInc(  
    int    delta=1           // minutes  
)
```

Parameters

delta

[in] Minutes to add.

Return Value

None.

HourDec

Subtracts specified number of hours.

```
void HourDec (  
    int    delta=1        // hours  
)
```

Parameters

delta

[in] Hours to subtract.

Return Value

None.

HourInc

Adds specified number of hours.

```
void HourInc (  
    int    delta=1        // hours  
)
```

Parameters

delta

[in] Hours to add.

Return Value

None.

DayDec

Subtracts specified number of days.

```
void DayDec(  
    int    delta=1      // days  
)
```

Parameters

delta

[in] Days to subtract.

Return Value

None.

DayInc

Adds specified number of days.

```
void DayInc(  
    int    delta=1      // days  
)
```

Parameters

delta

[in] Days to add.

Return Value

None.

MonDec

Subtracts specified number of months.

```
void MonDec(  
    int    delta=1      // months  
)
```

Parameters

delta

[in] Months to subtract.

Return Value

None.

MonInc

Adds specified number of months.

```
void MonInc(  
    int    delta=1        // months  
)
```

Parameters

delta

[in] Months to add.

Return Value

None.

YearDec

Subtracts specified number of years.

```
void YearDec (
    int    delta=1      // years
)
```

Parameters

delta

[in] Years to subtract.

Return Value

None.

YearInc

Adds specified number of years.

```
void YearInc(  
    int    delta=1    // years  
)
```

Parameters

delta

[in] Years to add.

Return Value

None.

CWnd

CWnd is a base class for all Standard Library controls.

Description

CWnd class is the implementation of the base control class.

Declaration

```
class CWnd : public CObject
```

Title

```
#include <Controls\Wnd.mqh>
```

Inheritance hierarchy

CObject

CWnd

Direct descendants

CDragWnd, CWndContainer, CWndObj

Class Methods by Groups

Create and destroy	
<u>Create</u>	Creates control
<u>Destroy</u>	Destroys control
Chart event handlers	
<u>OnEvent</u>	Event handler of all chart events
<u>OnMouseEvent</u>	Event handler for the <u>CHARTEVENT_MOUSE_MOVE</u> event
Name	
<u>Name</u>	Gets control name
Access to container	
<u>ControlsTotal</u>	Gets the number of controls in the container
<u>Control</u>	Gets the control by index
<u>ControlFind</u>	Gets the control by ID
Geometry	
<u>Rect</u>	Gets the control coordinates

Left	Gets/sets the X coordinate of the upper-left corner
Top	Gets/sets the Y coordinate of the upper-left corner
Right	Gets/sets the X coordinate of the lower-right corner
Bottom	Gets/sets the Y coordinate of the lower-right corner
Width	Gets/sets the control width
Height	Gets/sets the control height
Move	Control absolute displacement
Shift	Control relative displacement
Resize	Changes control size
Contains	Checks if the point/control is inside the control area
Align	
Alignment	Sets alignment properties of the control
Align	Performs control alignment in the specified chart area
Identification	
Id	Gets/sets the control ID
State	
IsEnabled	Checks the control ability to respond to user's actions
Enable	Enables the control ability to respond to user's actions
Disable	Disables the control ability to respond to user's actions
IsVisible	Checks the visibility flag
Visible	Sets the visibility flag
Show	Shows the control
Hide	Hides the control
IsActive	Checks the control activity
Activate	Activates the control
Deactivate	Deactivates the control

State flags	
StateFlags	Gets/sets the control state flags
StateFlagsSet	Sets the control state flags
StateFlagsReset	Resets the control state flags
Properties flags	
PropFlags	Gets/sets the control properties flags
PropFlagsSet	Sets the control properties flags
PropFlagsReset	Resets the control properties flags
Mouse operations	
MouseX	Gets/saves the mouse X coordinate
MouseY	Gets/saves the mouse Y coordinate
MouseFlags	Gets/saves the mouse buttons state
MouseFocusKill	Kills mouse focus
Internal event handlers	
OnCreate	"Create" event handler
OnDestroy	"Destroy" event handler
OnMove	"Move" event handler
OnResize	"Resize" event handler
OnEnable	"Enable" event handler
OnDisable	"Disable" event handler
OnShow	"Show" event handler
OnHide	"Hide" event handler
OnActivate	"Activate" event handler
OnDeactivate	"Deactivate" event handler
OnClick	"Click" event handler
OnChange	"Change" event handler
Mouse event handlers	
OnMouseDown	"MouseDown" event handler
OnMouseUp	"MouseUp" event handler
Drag event handlers	
OnDragStart	"DragStart" event handler

OnDragProcess	"DragProcess" event handler
OnDragEnd	"DragEnd" event handler
Drag object	
DragObjectCreate	Creates drag object
DragObjectDestroy	Destroys drag object

Methods inherited from class CObject

Prev, Prev, Next, Next, [Save](#), [Load](#), [Type](#), [Compare](#)

Create

Creates a control.

```
virtual bool Create(  
    const long    chart,      // chart ID  
    const string  name,      // name  
    const int     subwin,     // chart subwindow  
    const int     x1,         // x1 coordinate  
    const int     y1,         // y1 coordinate  
    const int     x2,         // x2 coordinate  
    const int     y2         // y2 coordinate  
)
```

Parameters

chart

[in] ID of the chart, at which the control is created.

name

[in] Unique name of the control.

subwin

[in] Chart subwindow, at which the control is created.

x1

[in] X coordinate of the upper-left corner.

y1

[in] Y coordinate of the upper-left corner.

x2

[in] X coordinate of the lower-right corner.

y2

[in] Y coordinate of the lower-right corner.

Return Value

true - successful, otherwise - false.

Note

Base class method only saves the creation parameters and always returns true.

Destroy

Destroys a control.

```
virtual bool Destroy()
```

Return Value

true - successful, otherwise - false.

OnEvent

Chart event handler.

```
virtual bool OnEvent(  
    const int      id,           // ID  
    const long&    lparam,       // event parameter  
    const double&  dparam,       // event parameter  
    const string&  sparam        // event parameter  
)
```

Parameters

id

[in] Event ID.

lparam

[in] Event parameter of [long](#) type, passed by reference.

dparam

[in] Event parameter of [double](#) type, passed by reference.

sparam

[in] Event parameter of [string](#) type, passed by reference.

Return Value

true - event has been processed, otherwise - false.

OnMouseEvent

Mouse event handler (the [CHARTEVENT_MOUSE_MOVE](#) chart event).

```
virtual bool OnMouseEvent (  
    const int x,           // x coordinate  
    const int y,           // y coordinate  
    const int flags        // flags  
)
```

Parameters

x

[in] X coordinate of the mouse cursor relative to the upper-left corner of the chart.

y

[in] Y coordinate of the mouse cursor relative to the upper-left corner of the chart.

flags

[in] Flag of mouse buttons states.

Return Value

true - event has been processed, otherwise - false.

Name

Gets control name.

```
string Name() const
```

Return Value

Control name.

ControlsTotal

Gets the number of controls in the container.

```
int ControlsTotal() const
```

Return Value

Number of controls in container.

Note

The base class method does not have the container, it provides the access to container for its heirs and always returns 0.

Control

Gets the control from the container by index.

```
CWnd* Control(  
    const int ind    // index  
    ) const
```

Parameters

ind

[in] Control index.

Return Value

A pointer to the control.

Note

The base class method does not have the container, it provides the access to container for its heirs and always returns NULL.

ControlFind

Gets the control from container by specified ID.

```
virtual CWnd* ControlFind(  
    const long id      // ID  
)
```

Parameters

id

[in] Identifier of the control to find.

Return Value

Pointer to the control from the container.

Note

The base class method does not have the container, it provides the access to container for its heirs. If the specified ID matches the container's one, it returns a pointer to itself (this).

Rect

Gets the pointer to the CRect class object.

```
const CRect* Rect () const
```

Return Value

Pointer to the CRect class object.

Left (Get Method)

Gets the X coordinate of the upper-left corner of the control.

```
int Left()
```

Return Value

X coordinate of the upper-left corner of the control.

Left (Set Method)

Sets the X coordinate of the upper-left corner of the control.

```
void Left(  
    const int x    // coordinate  
)
```

Parameters

x

[in] New X coordinate of the upper-left corner.

Return Value

None.

Top (Get Method)

Gets the Y coordinate of the upper-left corner of the control.

```
int Top()
```

Return Value

Y coordinate of the upper-left corner of the control.

Top (Set Method)

Sets the Y coordinate of the upper-left corner of the control.

```
void Top(  
    const int y    // y coordinate  
)
```

Parameters

y

[in] New Y coordinate of the upper-left corner.

Return Value

None.

Right (Get Method)

Gets the X coordinate of the lower-right corner of the control.

```
int Right()
```

Return Value

X coordinate of the lower-right corner.

Right (Set Method)

Sets the X coordinate of the lower-right corner of the control.

```
void Right(  
    const int x    // x coordinate  
)
```

Parameters

x

[in] New X coordinate of the lower-right corner.

Return Value

None.

Bottom (Get Method)

Gets the Y coordinate of the lower-right corner of the control.

```
int Bottom()
```

Return Value

Y coordinate of the lower-right corner of the control.

Bottom (Set Method)

Sets the Y coordinate of the lower-right corner of the control.

```
void Bottom(  
    const int y    // y coordinate  
)
```

Parameters

y

[in] New Y coordinate of the lower-right corner.

Return Value

None.

Width (Get Method)

Gets the control width.

```
int Width()
```

Return Value

Width of the control.

Width (Set Method)

Sets the width of the control.

```
virtual bool Width(  
    const int w    // width  
)
```

Parameters

w

[in] New width.

Return Value

true - successful, otherwise - false.

Height (Get Method)

Gets the control height.

```
int Height()
```

Return Value

Height of the control.

Height (Set Method)

Sets new height of the control.

```
virtual bool Height(  
    const int h    // height  
)
```

Parameters

h

[in] New height.

Return Value

true - successful, otherwise - false.

Move

Performs absolute displacement of a control.

```
void Move(  
    const int x,      // x coordinate  
    const int y      // y coordinate  
)
```

Parameters

x

[in] New X coordinate of the upper-left point.

y

[in] New Y coordinate of the upper-left point.

Return Value

true - successful, otherwise - false.

Shift

Performs the relative shift of a control.

```
void Shift(  
    const int dx,      // delta X  
    const int dy      // delta Y  
)
```

Parameters

dx

[in] Delta X.

dy

[in] Delta Y.

Return Value

true - successful, otherwise - false.

Resize

Sets a size of the control.

```
virtual bool  Resize(  
    const int  w,  
    const int  h  
)
```

Parameters

w

[in] New width.

h

[in] New height.

Return Value

true - successful, otherwise - false.

Contains

Checks if the point is inside the control area of the chart.

```
bool Contains(  
    const int x,      // X coordinate  
    const int y      // Y coordinate  
)
```

Parameters

x

[in] X coordinate.

y

[in] Y coordinate.

Return Value

true - the point is inside the area (including borders), otherwise - false.

Contains

Checks if the specified control is inside the control area of the chart.

```
bool Contains(  
    const CWnd* control // pointer  
) const
```

Parameters

control

[in] Object pointer.

Return Value

true - the specified control is inside the area (including borders), otherwise - false.

Alignment

Sets alignment parameters of the control.

```
void Alignment(  
    const int  flags,      // flags  
    const int  left,       // offset  
    const int  top,        // offset  
    const int  right,      // offset  
    const int  bottom     // offset  
)
```

Parameters

flags

[in] Alignment flags.

left

[in] Fixed offset from the left border.

top

[in] Fixed offset from the top border.

right

[in] Fixed offset from the right border.

bottom

[in] Fixed offset from the bottom border.

Return Value

None.

Note

Alignement flags:

```
enum WND_ALIGN_FLAGS  
{  
    WND_ALIGN_NONE=0,           // no align  
    WND_ALIGN_LEFT=1,          // align left  
    WND_ALIGN_TOP=2,           // align top  
    WND_ALIGN_RIGHT=4,         // align right  
    WND_ALIGN_BOTTOM=8,        // align bottom  
    WND_ALIGN_WIDTH = WND_ALIGN_LEFT|WND_ALIGN_RIGHT, // align width  
    WND_ALIGN_HEIGHT=WND_ALIGN_TOP|WND_ALIGN_BOTTOM,  // align height  
    WND_ALIGN_CLIENT=WND_ALIGN_WIDTH|WND_ALIGN_HEIGHT, // align height and width  
}
```

Align

Performs control alignment in the specified chart area.

```
virtual bool Align(  
    const CRect* rect    // pointer  
)
```

Parameters

rect

[in] Pointer to the object with chart area coordinates.

Return Value

true - successful, otherwise - false.

Note

The alignment parameters must be specified (no alignment by default).

Id (Get Method)

Gets the control ID.

```
long Id() const
```

Return Value

The control identifier.

Id (Set Method)

Sets the value of the control ID.

```
virtual long Id(  
    const long id    // identifier  
)
```

Parameters

id

[in] New value of the control identifier.

Return Value

None.

IsEnabled

Checks the control ability to respond to user's actions.

```
bool IsEnabled() const
```

Return Value

true - control is enabled, otherwise - false.

Enable

Enables the control ability to respond to user's actions.

```
virtual bool Enable()
```

Return Value

true - successful, otherwise - false.

Note

If the control is enabled, it is able to process the external events.

Disable

Disables the control ability to respond to user's actions.

```
virtual bool Disable()
```

Return Value

true - successful, otherwise - false.

Note

The disabled control is not able to process the external events.

IsVisible

Checks whether the control is visible.

```
bool IsVisible() const
```

Return Value

true - control is shown on the chart, otherwise - false.

Visible

Sets the visibility flag.

```
virtual bool Visible(  
    const bool flag    // flag  
)
```

Parameters

flag

[in] New flag.

Return Value

true - successful, otherwise - false.

Show

Shows the control.

```
virtual bool Show()
```

Return Value

true - successful, otherwise - false.

Hide

Hides the control.

```
virtual bool Hide()
```

Return Value

true - successful, otherwise - false.

IsActive

Gets a value indicating whether the control is active.

```
bool IsActive() const
```

Return Value

true - control is active, otherwise - false.

Activate

Activates the control.

```
virtual bool Activate()
```

Return Value

true - successful, otherwise - false.

Note

The control becomes active when the mouse cursor is hovering over it.

Deactivate

Deactivates the control.

```
virtual bool Deactivate()
```

Return Value

true - successful, otherwise - false.

Note

The control becomes inactive when the mouse cursor is out off the control.

StateFlags (Get Method)

Gets the control state flags.

```
int StateFlags()
```

Return Value

The control state flags.

StateFlags (Set Method)

Sets the control state flags.

```
virtual void StateFlags (  
    const int flags    // flags  
)
```

Parameters

flags

[in] New control state flags.

Return Value

None.

StateFlagsSet

Sets the control state flags.

```
virtual void StateFlagsSet(  
    const int flags    // flags  
)
```

Parameters

flags

[in] Flags to set.

Return Value

None.

StateFlagsReset

Resets the control state flags.

```
virtual void StateFlagsReset(  
    const int flags    // flags  
)
```

Parameters

flags

[in] Flags to reset.

Return Value

None.

PropFlags (Get Method)

Gets the control properties flags.

```
void PropFlags(  
    const int flags    // flags  
)
```

Return Value

The control properties flags.

PropFlags (Set Method)

Sets the control properties flags.

```
virtual void PropFlags(  
    const int flags    // flags  
)
```

Parameters

flags

[in] New flags.

Return Value

None.

PropFlagsSet

Sets the control properties flags.

```
virtual void PropFlagsSet(  
    const int flags    // flags  
)
```

Parameters

flags

[in] Flags to set.

Return Value

None.

PropFlagsReset

Resets the control properties flags.

```
virtual void PropFlagsReset(  
    const int flags    // flags  
)
```

Parameters

flags

[in] Flags to reset.

Return Value

None.

MouseX (Set Method)

Saves the mouse X coordinate.

```
void MouseX(  
    const int value    // coordinate  
)
```

Parameters

value

[in] The X coordinate of the mouse.

Return Value

None.

MouseX (Get Method)

Gets the saved X coordinate of the mouse.

```
int MouseX()
```

Return Value

The X coordinate of the mouse.

MouseY (Set Method)

Saves the mouse Y coordinate.

```
void MouseY(  
    const int value    // coordinate  
)
```

Parameters

value

[in] The Y coordinate of the mouse.

Return Value

None.

MouseY (Get Method)

Gets the saved Y coordinate of the mouse.

```
int MouseY()
```

Return Value

The Y coordinate of the mouse.

MouseFlags (Set Method)

Saves the state of mouse buttons.

```
virtual void MouseFlags(  
    const int value    // state  
)
```

Parameters

value

[in] State of mouse buttons.

Return Value

None.

MouseFlags (Get Method)

Gets the saved state of mouse buttons.

```
int MouseFlags()
```

Return Value

State of mouse buttons.

MouseFocusKill

Clears the saved state of mouse buttons and deactivates the control.

```
bool MouseFocusKill(  
    const long id=CONTROLS_INVALID_ID    // id  
)
```

Parameters

id=CONTROLS_INVALID_ID

[in] Identifier of the control, that received mouse focus.

Return Value

The control deactivation result.

OnCreate

The virtual handler of the internal "Create" event.

```
virtual bool OnCreate()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.

OnDestroy

The virtual handler of the internal "Destroy" event.

```
virtual bool OnDestroy()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.

OnMove

The virtual handler of the internal "Move" event.

```
virtual bool OnMove()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.

OnResize

The virtual handler of the internal "Resize" event.

```
virtual bool OnResize()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.

OnEnable

The virtual handler of the internal "Enable" event (if enabled, it can respond to user interaction).

```
virtual bool OnEnable()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.

OnDisable

The virtual handler of the internal "Disable" event (if disabled, it cannot respond to user interaction).

```
virtual bool OnDisable()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.

OnShow

The virtual handler of the internal "Show" event.

```
virtual bool OnShow()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.

OnHide

The virtual handler of the internal "Hide" event.

```
virtual bool OnHide()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.

OnActivate

The virtual handler of the internal "Activate" event.

```
virtual bool OnActivate()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.

OnDeactivate

The virtual handler of the internal "Deactivate" event.

```
virtual bool OnDeactivate()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.

OnClick

The virtual handler of the internal "Click" event (mouse click).

```
virtual bool OnClick()
```

Return Value

true - event processed, otherwise - false.

OnChange

The virtual handler of the internal "Change" event.

```
virtual bool OnChange()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.

OnMouseDown

The virtual handler of the "MouseDown" (mouse click) event.

```
virtual bool OnMouseDown()
```

Return Value

true - event processed, otherwise - false.

Note

The "MouseDown" event occurs when left mouse button is pressed on the control.

OnMouseUp

The virtual handler of the "MouseUp" (mouse button release) event.

```
virtual bool OnMouseUp()
```

Return Value

true - event processed, otherwise - false.

Note

The "MouseUp" event occurs when left mouse button is released on the control.

OnDragStart

The virtual handler of the "DragStart" (start dragging) event.

```
virtual bool OnDragStart()
```

Return Value

true - event processed, otherwise - false.

Note

The "DragStart" event occurs at the start of control dragging operation.

OnDragProcess

The virtual handler of the "DragProcess" (dragging) event.

```
virtual bool OnDragProcess(  
    const int x,      // x coordinate  
    const int y      // y coordinate  
)
```

Parameters

x

[in] Current X coordinate of mouse cursor.

y

[in] Current Y coordinate of mouse cursor.

Return Value

true - event processed, otherwise - false.

Note

The "DragProcess" event occurs when the control is dragged.

OnDragEnd

The virtual handler of the "DragEnd" event.

```
virtual bool OnDragEnd()
```

Return Value

true - event processed, otherwise - false.

Note

The "DragEnd" event occurs when control drag process is finished.

DragObjectCreate

Creates drag object.

```
virtual bool DragObjectCreate ()
```

Return Value

true - successful, otherwise - false.

Note

true - event processed, otherwise - false.

DragObjectDestroy

Destroys drag object.

```
virtual bool DragObjectDestroy()
```

Return Value

true - successful, otherwise - false.

CWndObj

CWndObj is a base class for simple controls (based on chart objects) of the Standard Library.

Description

CWndObj class implements base methods of the simple control.

Declaration

```
class CWndObj : public CWnd
```

Title

```
#include <Controls\WndObj.mqh>
```

Inheritance hierarchy

[CObject](#)

[CWnd](#)

CWndObj

Direct descendants

[CBmpButton](#), [CButton](#), [CEdit](#), [CLabel](#), [CPanel](#), [CPicture](#)

Class Methods by Groups

Chart events processing	
OnEvent	Event handler of all chart events
Properties	
Text	Gets/sets the OBJPROP_TEXT property of the chart object
Color	Gets/sets the OBJPROP_COLOR property of the chart object
ColorBackground	Gets/sets the OBJPROP_BGCOLOR property of the chart object
ColorBorder	Gets/sets the OBJPROP_BORDER_COLOR property of the chart object
Font	Gets/sets the OBJPROP_FONT property of the chart object
FontSize	Gets/sets the OBJPROP_FONTSIZE property of the chart object
ZOrder	Gets/sets the OBJPROP_ZORDER property of the chart object

Chart objects event handlers	
OnObjectCreate	CHARTEVENT_OBJECT_CREATE event handler
OnObjectChange	CHARTEVENT_OBJECT_CHANGE event handler
OnObjectDelete	CHARTEVENT_OBJECT_DELETE event handler
OnObjectDrag	CHARTEVENT_OBJECT_DRAG event handler
Properties change event handlers	
OnSetText	"SetText" event handler
OnSetColor	"SetColor" event handler
OnSetColorBackground	"SetColorBackground" event handler
OnSetFont	"SetFont" event handler
OnSetFontSize	"SetFontSize" event handler
OnSetZOrder	"SetZOrder" event handler
Internal event handlers	
OnDestroy	"Destroy" internal event handler
OnChange	"Change" internal event handler

Methods inherited from class CObject

Prev, Prev, Next, Next, [Save](#), [Load](#), [Type](#), [Compare](#)

Methods inherited from class CWnd

[Create](#), [Destroy](#), [OnMouseEvent](#), [Name](#), [ControlsTotal](#), [Control](#), [ControlFind](#), [Rect](#), [Left](#), [Left](#), [Top](#), [Top](#), [Right](#), [Right](#), [Bottom](#), [Bottom](#), [Width](#), [Width](#), [Height](#), [Height](#), [Size](#), [Size](#), [Size](#), [Move](#), [Move](#), [Shift](#), [Contains](#), [Contains](#), [Alignment](#), [Align](#), [Id](#), [Id](#), [IsEnabled](#), [Enable](#), [Disable](#), [IsVisible](#), [Visible](#), [Show](#), [Hide](#), [IsActive](#), [Activate](#), [Deactivate](#), [StateFlags](#), [StateFlags](#), [StateFlagsSet](#), [StateFlagsReset](#), [PropFlags](#), [PropFlags](#), [PropFlagsSet](#), [PropFlagsReset](#), [MouseX](#), [MouseX](#), [MouseY](#), [MouseY](#), [MouseFlags](#), [MouseFlags](#), [MouseFocusKill](#), [BringToTop](#)

OnEvent

Chart event handler.

```
virtual bool OnEvent(  
    const int      id,           // ID  
    const long&    lparam,       // parameter  
    const double&  dparam,       // parameter  
    const string&  sparam        // parameter  
)
```

Parameters

id

[in] Event ID.

lparam

[in] Event parameter of [long](#) type, passed by reference.

dparam

[in] Event parameter of [double](#) type, passed by reference.

sparam

[in] Event parameter of [string](#) type, passed by reference.

Return Value

true - event processed, otherwise - false.

Text (Get method)

Gets the [OBJPROP_TEXT](#) (text) property of the chart object.

```
string Text()
```

Return Value

The value of the [OBJPROP_TEXT](#) property.

Text (Set method)

Sets the [OBJPROP_TEXT](#) (text) property of the chart object.

```
bool Text (  
    const string value    // value  
)
```

Parameters

value

[in] New value of the [OBJPROP_TEXT](#) property.

Return Value

true - successful, otherwise - false.

Color (Get method)

Gets the [OBJPROP_COLOR](#) (color) property of the chart object.

```
color Color()
```

Return Value

The value of the [OBJPROP_COLOR](#) property.

Color (Set method)

Sets the [OBJPROP_COLOR](#) (color) property of the chart object.

```
bool Color(  
    const color value    // value  
)
```

Parameters

value

[in] New value of the [OBJPROP_COLOR](#) property.

Return Value

true - successful, otherwise - false.

ColorBackground (Get method)

Gets the [OBJPROP_BGCOLOR](#) (background color) of the chart object.

```
color ColorBackground()
```

Return Value

The value of the [OBJPROP_BGCOLOR](#) property.

ColorBackground (Set method)

Sets the [OBJPROP_BGCOLOR](#) (background color) property of the chart object.

```
bool ColorBackground(  
    const color value    // value  
)
```

Parameters

value

[in] New value of the [OBJPROP_BGCOLOR](#) property.

Return Value

true - successful, otherwise - false.

ColorBorder (Get method)

Gets the [OBJPROP_BORDER_COLOR](#) (border color) property of the chart object.

```
color ColorBorder ()
```

Return Value

The value of the [OBJPROP_BORDER_COLOR](#) property.

ColorBorder (Set method)

Sets the [OBJPROP_BORDER_COLOR](#) (border color) property of the chart object.

```
bool ColorBorder (
    const color value    // value
)
```

Parameters

value

[in] New value of the [OBJPROP_BORDER_COLOR](#) property.

Return Value

true - successful, otherwise - false.

Font (Get method)

Gets the [OBJPROP_FONT](#) (font) property of the chart object.

```
string Font()
```

Return Value

The value of the [OBJPROP_FONT](#) property.

Font (Set method)

Sets the [OBJPROP_FONT](#) (font) property of the chart object.

```
bool Font(  
    const string value    // value  
)
```

Parameters

value

[in] New value of the [OBJPROP_FONT](#) property.

Return Value

true - successful, otherwise - false.

FontSize (Get method)

Gets the [OBJPROP_FONTSIZE](#) (font size) property of the chart object.

```
int FontSize()
```

Return Value

The value of the [OBJPROP_FONTSIZE](#) property.

FontSize (Set method)

Sets the [OBJPROP_FONTSIZE](#) (font size) property of the chart object.

```
bool FontSize(  
    const int value    // value  
)
```

Parameters

value

[in] New value of the [OBJPROP_FONTSIZE](#) property.

Return Value

true - successful, otherwise - false.

ZOrder (Get method)

Gets the [OBJPROP_ZORDER](#) property of the chart object.

```
long ZOrder()
```

Return Value

The value of the [OBJPROP_ZORDER](#) property.

ZOrder (Set method)

Sets the [OBJPROP_ZORDER](#) property of the chart object.

```
bool ZOrder(  
    const long value // value  
)
```

Parameters

value

[in] New value of the [OBJPROP_ZORDER](#) property.

Return Value

true - successful, otherwise - false.

OnObjectCreate

The virtual handler of chart object [CHARTEVENT_OBJECT_CREATE](#) event.

```
virtual bool OnObjectCreate()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.

OnObjectChange

The virtual handler of chart object [CHARTEVENT_OBJECT_CHANGE](#) event.

```
virtual bool OnObjectChange ()
```

Return Value

true - event processed, otherwise - false.

OnObjectDelete

The virtual handler of chart object [CHARTEVENT_OBJECT_DELETE](#) event.

```
virtual bool OnObjectDelete()
```

Return Value

true - event processed, otherwise - false.

OnObjectDrag

The virtual handler of chart object [CHARTEVENT_OBJECT_DRAG](#) event.

```
virtual bool OnObjectDrag()
```

Return Value

true - event processed, otherwise - false.

OnSetText

The virtual handler of control "SetText" (change of the [OBJPROP_TEXT](#) property) event.

```
virtual bool OnSetText()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.

OnSetColor

The virtual handler of control "SetColor" (change of the [OBJPROP_COLOR](#) property) event.

```
virtual bool OnSetColor()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.

OnSetColorBackground

The virtual handler of control "SetColorBackground" (change of the [OBJPROP_BGCOLOR](#) property) event.

```
virtual bool OnSetColorBackground()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.

OnSetFont

The virtual handler of "SetFont" (change of the [OBJPROP_FONT](#) property) event.

```
virtual bool OnSetFont()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.

OnSetFontSize

The virtual handler of "SetFontSize" (change of the [OBJPROP_FONTSIZE](#) property) event.

```
virtual bool OnSetFontSize()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.

OnSetZOrder

The virtual handler of "SetZOrder" (change of the [OBJPROP_ZORDER](#) property) event.

```
virtual bool OnSetZOrder()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.

OnDestroy

The virtual handler of control "Destroy" internal event.

```
virtual bool OnDestroy()
```

Return Value

true - event processed, otherwise - false.

OnChange

The virtual handler of control "Change" internal event.

```
virtual bool OnChange()
```

Return Value

true - event processed, otherwise - false.

CWndContainer

CWndContainer is a base class for a complex control (containing dependent controls) of the Standard library.

Description

CWndContainer class implements base methods of the complex control.

Declaration

```
class CWndContainer : public CWnd
```

Title

```
#include <Controls\WndContainer.mqh>
```

Inheritance hierarchy

[CObject](#)

[CWnd](#)

CWndContainer

Direct descendants

[CCheckBox](#), [CComboBox](#), [CDateDropList](#), [CDatePicker](#), [CDialog](#), [CRadioButton](#), [CScroll](#), [CSpinEdit](#), [CWndClient](#)

Class Methods by Groups

Destroy	
Destroy	Destroys all the container controls
Chart event handlers	
OnEvent	Event handler of all chart events
OnMouseEvent	The CHARTEVENT_MOUSE_MOVE event handler
Access to container	
ControlsTotal	Gets the number of controls in the container
Control	Gets control by index
ControlFind	Gets control by ID
Add/Delete	
Add	Adds control to a group (container)
Delete	Deletes control from a group (container)
Geometry	

Move	Performs a absolute displacement of an element group
Shift	Performs a relative displacement of an element group
Identification	
Id	Sets the ID for all controls of the container
State	
Enable	Enables all controls of the container
Disable	Disables all controls of the container
Show	Shows all controls of the container
Hide	Hides all controls of the container
Mouse operations	
MouseFocusKill	Kills mouse focus
File operations	
Save	Saves container information to file
Load	Loads container information from file
Internal event handlers	
OnResize	"Resize" event handler
OnActivate	"Activate" event handler
OnDeactivate	"Deactivate" event handler

Methods inherited from class CObject

Prev, Prev, Next, Next, [Type](#), [Compare](#)

Methods inherited from class CWnd

[Create](#), [Name](#), [ControlsTotal](#), [Control](#), [Rect](#), [Left](#), [Left](#), [Top](#), [Top](#), [Right](#), [Right](#), [Bottom](#), [Bottom](#), [Width](#), [Width](#), [Height](#), [Height](#), [Size](#), [Size](#), [Size](#), [Contains](#), [Contains](#), [Alignment](#), [Align](#), [Id](#), [IsEnabled](#), [IsVisible](#), [Visible](#), [IsActive](#), [Activate](#), [Deactivate](#), [StateFlags](#), [StateFlags](#), [StateFlagsSet](#), [StateFlagsReset](#), [PropFlags](#), [PropFlags](#), [PropFlagsSet](#), [PropFlagsReset](#), [MouseX](#), [MouseX](#), [MouseY](#), [MouseY](#), [MouseFlags](#), [MouseFlags](#), [MouseFocusKill](#), [BringToTop](#)

Destroy

Destroys all the container controls.

```
virtual bool Destroy()
```

Return Value

true - successful, otherwise - false.

OnEvent

Chart event handler.

```
virtual bool OnEvent(  
    const int      id,           // ID  
    const long&    lparam,      // parameter  
    const double&  dparam,      // parameter  
    const string&  sparam       // parameter  
)
```

Parameters

id

[in] Event ID.

lparam

[in] Event parameter of [long](#) type, passed by reference.

dparam

[in] Event parameter of [double](#) type, passed by reference.

sparam

[in] Event parameter of [string](#) type, passed by reference.

Return Value

true - event processed, otherwise - false.

OnMouseEvent

Mouse event handler.

```
virtual bool OnMouseEvent (  
    const int x,           // x coordinate  
    const int y,           // y coordinate  
    const int flags        // flags  
)
```

Parameters

x

[in] X coordinate of the mouse cursor relative to the upper-left corner of the chart.

y

[in] Y coordinate of the mouse cursor relative to the upper-left corner of the chart.

flags

[in] Flag of mouse buttons states.

Return Value

true - event processed, otherwise - false.

ControlsTotal

Gets the number of controls in the container.

```
int ControlsTotal() const
```

Return Value

Number of controls in the container.

Control

Gets control from the container by index.

```
CWnd* Control(  
    const int ind    // index  
) const
```

Parameters

ind

[in] Index of the control needed.

Return Value

Pointer to the control, otherwise NULL if the control is not found.

ControlFind

Gets control from the container by identifier.

```
virtual CWnd* ControlFind(  
    const long id    // id  
)
```

Parameters

id

[in] Control ID.

Return Value

Pointer to the control, otherwise NULL if the control is not found.

Add

Adds a control to a group (container).

```
bool Add(  
    CWnd& control    // reference  
)
```

Parameters

control

[in] Control to add, passed by reference.

Return Value

true - successful, otherwise - false.

Delete

Deletes control from a group (container).

```
bool Delete(  
    CWnd& control    // reference  
)
```

Parameters

control

[in] Control to delete, passed by reference.

Return Value

true - successful, otherwise - false.

Move

Performs an absolute displacement of all controls of the container.

```
virtual bool Move(  
    const int x,      // X coordinate  
    const int y      // Y coordinate  
)
```

Parameters

x

[in] New X coordinate of the upper-left corner.

y

[in] New Y coordinate of the upper-left corner.

Return Value

true - successful, otherwise - false.

Shift

Performs the relative shift of the coordinates for all controls of the container.

```
virtual bool Shift(  
    const int dx,      // delta X  
    const int dy      // delta Y  
)
```

Parameters

dx

[in] Delta X.

dy

[in] Delta Y.

Return Value

true - successful, otherwise - false.

Id

Sets the ID for all controls of the container.

```
virtual long Id(  
    const long id    // identifier  
)
```

Parameters

id

[in] Base group identifier.

Return Value

Number of identifiers used by container controls.

Enable

Enables all the controls of the container.

```
virtual bool Enable()
```

Return Value

true - successful, otherwise - false.

Disable

Disables all controls of the container.

```
virtual bool Disable()
```

Return Value

true - successful, otherwise - false.

Show

Shows all controls of the container.

```
virtual bool Show()
```

Return Value

true - successful, otherwise - false.

Hide

Hides all controls of the container.

```
virtual bool Hide()
```

Return Value

true - successful, otherwise - false.

MouseFocusKill

Clears the saved state of mouse buttons and deactivates all controls in the container.

```
bool MouseFocusKill(  
    const long id=CONTROLS_INVALID_ID    // id  
)
```

Parameters

id=CONTROLS_INVALID_ID

[in] Identifier of the control, that received mouse focus.

Return Value

The controls deactivation result.

Save

Saves container information to file.

```
virtual bool Save(  
    const int file_handle    // handle  
)
```

Parameters

file_handle

[in] Handle of the binary file previously opened for writing.

Return Value

true - successful, otherwise - false.

Load

Loads container information from file

```
virtual bool Load(  
    const int file_handle // handle  
)
```

Parameters

file_handle

[in] Handle of the binary file previously opened for reading.

Return Value

true - successful, otherwise - false.

OnResize

The virtual handler of control "Resize" internal event.

```
virtual bool OnResize()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.

OnActivate

The virtual handler of control "Activate" internal event.

```
virtual bool OnActivate()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.

OnDeactivate

The virtual handler of control "Deactivate" internal event.

```
virtual bool OnDeactivate()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.

CLabel

CLabel is class of the simple control based on "Text label" chart object.

Description

CLabel is intended for creation of simple non-editable text labels.

Declaration

```
class CLabel : public CWndObj
```

Title

```
#include <Controls\Label.mqh>
```

Inheritance hierarchy

                  const string& sparam)  // event parameter of the string type
{
    ExtDialog.ChartEvent(id,lparam,dparam,sparam);
}

```

Create

Creates new CLabel control.

```
virtual bool Create(  
    const long    chart,      // chart ID  
    const string  name,      // name  
    const int     subwin,     // chart subwindow  
    const int     x1,        // x1 coordinate  
    const int     y1,        // y1 coordinate  
    const int     x2,        // x2 coordinate  
    const int     y2         // y2 coordinate  
)
```

Parameters

chart

[in] ID of the chart, at which the control is created.

name

[in] Unique name of the control.

subwin

[in] Subwindow of the chart, at which the control is created.

x1

[in] X coordinate of the upper left corner.

y1

[in] Y coordinate of the upper left corner.

x2

[in] X coordinate of the lower right corner.

y2

[in] Y coordinate of the lower right corner.

Return Value

true - successful, otherwise - false.

OnSetText

The virtual handler of control "SetText" (change of the [OBJPROP_TEXT](#) property) event.

```
virtual bool OnSetText()
```

Return Value

true - event processed, otherwise - false.

OnSetColor

The virtual handler of control "SetColor" (change of the [OBJPROP_COLOR](#) property) event.

```
virtual bool OnSetColor()
```

Return Value

true - event processed, otherwise - false.

OnSetFont

The virtual handler of control "SetFont" (change of the [OBJPROP_FONT](#) property) event.

```
virtual bool OnSetFont()
```

Return Value

true - event processed, otherwise - false.

OnSetFontSize

The virtual handler of control "SetFontSize" (change of the [OBJPROP_FONTSIZE](#) property) event.

```
virtual bool OnSetFontSize()
```

Return Value

true - event processed, otherwise - false.

OnCreate

The virtual handler of control "Create" internal event.

```
virtual bool OnCreate()
```

Return Value

true - event processed, otherwise - false.

OnShow

The virtual handler of control "Show" internal event.

```
virtual bool OnShow()
```

Return Value

true - event processed, otherwise - false.

OnHide

The virtual handler of control "Hide" internal event.

```
virtual bool OnHide()
```

Return Value

true - event processed, otherwise - false.

OnMove

The virtual handler of control "Move" internal event.

```
virtual bool OnMove()
```

Return Value

true - event processed, otherwise - false.

CBmpButton

CBmpButton is class of the simple control based on "Bitmap label" chart object.

Description

CBmpButton is intended for creation of buttons with graphic image.

Declaration

```
class CBmpButton : public CWndObj
```

Title

```
#include <Controls\BmpButton.mqh>
```

Inheritance hierarchy

- CObject
 - CWnd
 - CWndObj
 - CBmpButton

Result of the [code](#) provided below:

Class Methods by Groups

Create	
Create	Creates control

Properties	
Border	Gets/sets the "Border" property of the control
BmpNames	Sets the name of bmp files of the control
BmpOffName	Gets/sets the name of bmp file for the OFF state
BmpOnName	Gets/sets the name of bmp file for the ON state
BmpPassiveName	Gets/sets the name of bmp file for the passive state
BmpActiveName	Gets/sets the name of bmp file for the active state
State	
Pressed	Gets/sets the state of the control
Locking	Gets/sets the "Locking" property of the control
Internal event handlers	
OnSetZOrder	"SetZOrder" internal event handler
OnCreate	"Create" internal event handler
OnShow	"Show" internal event handler
OnHide	"Hide" internal event handler
OnMove	"Move" internal event handler
OnChange	"Change" internal event handler
OnActivate	"Activate" internal event handler
OnDeactivate	"Deactivate" internal event handler
OnMouseDown	"MouseDown" internal event handler
OnMouseUp	"MouseUp" internal event handler

```

Create

Creates new CBmpButton control.

```
virtual bool Create(  
    const long    chart,      // chart ID  
    const string  name,      // name  
    const int     subwin,     // chart subwindow  
    const int     x1,        // x1 coordinate  
    const int     y1,        // y1 coordinate  
    const int     x2,        // x2 coordinate  
    const int     y2         // y2 coordinate  
)
```

Parameters

chart

[in] ID of the chart, at which the control is created.

name

[in] Unique name of the control.

subwin

[in] Subwindow of the chart, at which the control is created.

x1

[in] X coordinate of the upper left corner.

y1

[in] Y coordinate of the upper left corner.

x2

[in] X coordinate of the lower right corner.

y2

[in] Y coordinate of the lower right corner.

Return Value

true - successful, otherwise - false.

Border (Get method)

Gets the "Border" (border width) property of the control.

```
int Border() const
```

Return Value

The "Border" property.

Border (Set method)

Sets the "Border" (border width) property of the control.

```
bool Border(  
    const int value    // value  
)
```

Parameters

value

[in] New value of the "Border" property.

Return Value

true - successful, otherwise - false.

BmpNames

Sets the name of bmp files of the control

```
bool BmpNames(  
    const string off="",      // file name  
    const string on=""        // file name  
)
```

Parameters

off=""

[in] Name of bmp file for OFF state.

on=""

[in] Name of bmp file for ON state.

Return Value

true - successful, otherwise - false.

BmpOffName (Get method)

Gets the name of bmp file for OFF state.

```
string BmpOffName() const
```

Return Value

Name of bmp file for OFF state.

BmpOffName (Set method)

Sets the name of bmp file for OFF state.

```
bool BmpOffName (  
    const string name    // file name  
)
```

Parameters

name

[in] Name of bmp file for OFF state.

Return Value

true - successful, otherwise - false.

BmpOnName (Get method)

Gets the name of bmp file for ON state.

```
string BmpOnName() const
```

Return Value

Name of bmp file for ON state.

BmpOnName (Set method)

Sets the name of bmp file for ON state.

```
bool BmpOnName (
    const string name    // file name
)
```

Parameters

name

[in] Name of bmp file for ON state.

Return Value

true - successful, otherwise - false.

BmpPassiveName (Get method)

Gets the name of bmp file for the control passive state.

```
string BmpPassiveName() const
```

Return Value

Name of bmp file for the control passive state.

BmpPassiveName (Set method)

Sets the name of bmp file for the passive state.

```
bool BmpPassiveName(  
    const string name    // file name  
)
```

Parameters

name

[in] Name of bmp file for the control passive state.

Return Value

true - successful, otherwise - false.

BmpActiveName (Get method)

Gets the name of bmp file for the active state.

```
string BmpActiveName() const
```

Return Value

Name of bmp file for the active state.

Note

The control becomes active when the mouse cursor is hovering over it.

BmpActiveName (Set method)

Sets the name of bmp file for the active state.

```
bool BmpActiveName(  
    const string name    // file name  
)
```

Parameters

name

[in] Name of bmp file for the active state.

Return Value

true - successful, otherwise - false.

Pressed (Get method)

Gets the state ("Pressed" property) of the control.

```
bool Pressed() const
```

Return Value

Control state.

Pressed (Set method)

Sets the state ("Pressed" property) of the control.

```
bool Pressed(  
    const bool pressed // state  
)
```

Parameters

pressed

[in] New control state.

Return Value

true - successful, otherwise - false.

Locking (Get method)

Gets the "Locking" property of the control.

```
bool Locking() const
```

Return Value

The value of "Locking" property.

Locking (Set method)

Sets new value of the "Locking" property of the control.

```
void Locking(  
    const bool locking    // value  
)
```

Parameters

locking

[in] New value of "Locking" property.

Return Value

None.

OnSetZOrder

The virtual handler of control "SetZOrder" (change of the [OBJPROP_ZORDER](#) property) event.

```
virtual bool OnSetZOrder()
```

Return Value

true - event processed, otherwise - false.

OnCreate

The virtual handler of control "Create" internal event.

```
virtual bool OnCreate()
```

Return Value

true - event processed, otherwise - false.

OnShow

The virtual handler of control "Show" internal event.

```
virtual bool OnShow()
```

Return Value

true - event processed, otherwise - false.

OnHide

The virtual handler of control "Hide" internal event.

```
virtual bool OnHide()
```

Return Value

true - event processed, otherwise - false.

OnMove

The virtual handler of control "Move" internal event.

```
virtual bool OnMove()
```

Return Value

true - event processed, otherwise - false.

OnChange

The virtual handler of control "Change" internal event.

```
virtual bool OnChange()
```

Return Value

true - event processed, otherwise - false.

OnActivate

The virtual handler of control "Activate" internal event.

```
virtual bool OnActivate()
```

Return Value

true - event processed, otherwise - false.

OnDeactivate

The virtual handler of control "Deactivate" internal event.

```
virtual bool OnDeactivate()
```

Return Value

true - event processed, otherwise - false.

OnMouseDown

The virtual handler of control "MouseDown" event.

```
virtual bool OnMouseDown()
```

Return Value

true - event processed, otherwise - false.

OnMouseUp

The virtual handler of control "MouseUp" (mouse button release) event.

```
virtual bool OnMouseUp()
```

Return Value

true - event processed, otherwise - false.

CButton

CButton is a class of a simple control based on "Button" chart object.

Description

CButton class is intended for creation of simple buttons.

Declaration

```
class CButton : public CWndObj
```

Title

```
#include <Controls\Button.mqh>
```

{
    ExtDialog.ChartEvent(id, lparam, dparam, sparam);
}
```

Create

Creates new CButton control.

```
virtual bool Create(  
    const long    chart,      // chart ID  
    const string  name,      // name  
    const int     subwin,    // chart subwindow  
    const int     x1,        // coordinate  
    const int     y1,        // coordinate  
    const int     x2,        // coordinate  
    const int     y2        // coordinate  
)
```

Parameters

chart

[in] ID of the chart, at which the control is created.

name

[in] Unique name of the control.

subwin

[in] Subwindow of the chart, at which the control is created.

x1

[in] X coordinate of the upper left corner.

y1

[in] Y coordinate of the upper left corner.

x2

[in] X coordinate of the lower right corner.

y2

[in] Y coordinate of the lower right corner.

Return Value

true - successful, otherwise - false.

Pressed (Get method)

Gets the state ("Pressed" property) of the control.

```
bool Pressed() const
```

Return Value

"Pressed" property of the control.

Pressed (Set method)

Sets the state ("Pressed" property) of the control.

```
bool Pressed(  
    const bool pressed // state  
)
```

Parameters

pressed

[in] New control state.

Return Value

true - successful, otherwise - false.

Locking (Get method)

Gets the "Locking" property of the control.

```
bool Locking() const
```

Return Value

The value of "Locking" property.

Locking (Set method)

Sets the value of "Locking" property of the control.

```
void Locking(  
    const bool locking    // value  
)
```

Parameters

locking

[in] New value of "Locking" property of the control.

Return Value

None.

OnSetText

The virtual handler of control "SetText" (change of the [OBJPROP_TEXT](#) property) event.

```
virtual bool OnSetText()
```

Return Value

true - event processed, otherwise - false.

OnSetColor

The virtual handler of control "SetColor" (change of the [OBJPROP_COLOR](#) property) event.

```
virtual bool OnSetColor()
```

Return Value

true - event processed, otherwise - false.

OnSetColorBackground

The virtual handler of control "SetColorBackground" (change of the [OBJPROP_BGCOLOR](#) property) event.

```
virtual bool OnSetColorBackground()
```

Return Value

true - event processed, otherwise - false.

OnSetColorBorder

The virtual handler of control "SetColorBorder" (change of the [OBJPROP_BORDER_COLOR](#) property) event.

```
virtual bool OnSetColorBackground()
```

Return Value

true - event processed, otherwise - false.

OnSetFont

The virtual handler of control "SetFont" (change of the [OBJPROP_FONT](#) property) event.

```
virtual bool OnSetFont()
```

Return Value

true - event processed, otherwise - false.

OnSetFontSize

The virtual handler of control "SetFontSize" (change of the [OBJPROP_FONTSIZE](#) property) event.

```
virtual bool OnSetFontSize()
```

Return Value

true - event processed, otherwise - false.

OnCreate

The virtual handler of control "Create" internal event.

```
virtual bool OnCreate()
```

Return Value

true - event processed, otherwise - false.

OnShow

The virtual handler of control "Show" internal event.

```
virtual bool OnShow()
```

Return Value

true - event processed, otherwise - false.

OnHide

The virtual handler of control "Hide" internal event.

```
virtual bool OnHide()
```

Return Value

true - event processed, otherwise - false.

OnMove

The virtual handler of control "Move" internal event.

```
virtual bool OnMove()
```

Return Value

true - event processed, otherwise - false.

OnResize

The virtual handler of control "Resize" internal event.

```
virtual bool OnResize()
```

Return Value

true - event processed, otherwise - false.

OnMouseDown

The virtual handler of control "MouseDown" event handler.

```
virtual bool OnMouseDown()
```

Return Value

true - event processed, otherwise - false.

Note

The "MouseDown" event occurs when left mouse button is pressed on the control.

OnMouseUp

The virtual handler of control "MouseUp" (left mouse button release) event.

```
virtual bool OnMouseUp()
```

Return Value

true - event processed, otherwise - false.

Note

The "MouseUp" event occurs when left mouse button is released on the control.

CEdit

CEdit is class of the simple control based on "Edit" chart object.

Description

CEdit class is intended for creation of controls, in which the user can enter text.

Declaration

```
class CEdit : public CWndObj
```

Title

```
#include <Controls\Edit.mqh>
```

Inheritance hierarchy

Result of the [code](#) provided below:

Class Methods by Groups

Create	
Create	Creates control

Properties

}

```

Create

Creates CEdit control.

```
virtual bool Create(  
    const long    chart,      // chart ID  
    const string  name,      // name  
    const int     subwin,     // chart subwindow  
    const int     x1,         // coordinate  
    const int     y1,         // coordinate  
    const int     x2,         // coordinate  
    const int     y2         // coordinate  
)
```

Parameters

chart

[in] ID of the chart, at which the control is created.

name

[in] Unique name of the control.

subwin

[in] Subwindow of the chart, at which the control is created.

x1

[in] X coordinate of the upper left corner.

y1

[in] Y coordinate of the upper left corner.

x2

[in] X coordinate of the lower right corner.

y2

[in] Y coordinate of the lower right corner.

Return Value

true - successful, otherwise - false.

ReadOnly (Get Method)

Gets the "ReadOnly" property of the control.

```
bool ReadOnly()
```

Return Value

The value of "ReadOnly" property.

ReadOnly (Set Method)

Sets the value of "ReadOnly" property of the control.

```
bool ReadOnly(  
    const bool flag    // value  
)
```

Parameters

flag

[in] New value of "ReadOnly" property.

Return Value

true - successful, otherwise - false.

TextAlign (Get method)

Gets the value of "TextAlign" property ([text alignment mode](#)) of the control.

```
ENUM_ALIGN_MODE TextAlign() const
```

Return Value

Value of "TextAlign" property of the control.

TextAlign (Set method)

Sets new value of "TextAlign" property ([text alignment mode](#)) of the control.

```
bool TextAlign(  
    ENUM_ALIGN_MODE align    // property value  
)
```

Parameters

align

[in] New value of "TextAlign" property.

Return Value

true - successful, false - cannot change the property.

OnObjectEndEdit

The virtual handler of [CHARTEVENT_OBJECT_ENDEDIT](#) chart object event.

```
virtual bool OnObjectEndEdit ()
```

Return Value

true - event processed, otherwise - false.

OnSetText

The virtual handler of control "SetText" (change of the [OBJPROP_TEXT](#) property) event.

```
virtual bool OnSetText()
```

Return Value

true - event processed, otherwise - false.

OnSetColor

The virtual handler of control "SetColor" (change of the [OBJPROP_COLOR](#) property) event.

```
virtual bool OnSetColor()
```

Return Value

true - event processed, otherwise - false.

OnSetColorBackground

The virtual handler of control "SetColorBackground" (change of the [OBJPROP_BGCOLOR](#) property) event.

```
virtual bool OnSetColorBackground()
```

Return Value

true - event processed, otherwise - false.

OnSetColorBorder

The virtual handler of control "SetColorBorder" (change of the [OBJPROP_BORDER_COLOR](#) property) event.

```
virtual bool OnSetColorBackground()
```

Return Value

true - event processed, otherwise - false.

OnSetFont

The virtual handler of control "SetFont" (change of the [OBJPROP_FONT](#) property) event.

```
virtual bool OnSetFont()
```

Return Value

true - event processed, otherwise - false.

OnSetFontSize

The virtual handler of control "SetFontSize" (change of the [OBJPROP_FONTSIZE](#) property) event.

```
virtual bool OnSetFontSize()
```

Return Value

true - event processed, otherwise - false.

OnSetZOrder

The virtual handler of control "SetZOrder" (change of the [OBJPROP_ZORDER](#) property) event.

```
virtual bool OnSetZOrder()
```

Return Value

true - event processed, otherwise - false.

OnCreate

The virtual handler of control "Create" internal event.

```
virtual bool OnCreate()
```

Return Value

true - event processed, otherwise - false.

OnShow

The virtual handler of control "Show" internal event.

```
virtual bool OnShow()
```

Return Value

true - event processed, otherwise - false.

OnHide

The virtual handler of control "Hide" internal event.

```
virtual bool OnHide()
```

Return Value

true - event processed, otherwise - false.

OnMove

The virtual handler of control "Move" internal event.

```
virtual bool OnMove()
```

Return Value

true - event processed, otherwise - false.

OnResize

The virtual handler of control "Resize" internal event.

```
virtual bool OnResize()
```

Return Value

true - event processed, otherwise - false.

OnChange

The virtual handler of control "Change" internal event.

```
virtual bool OnChange()
```

Return Value

true - event processed, otherwise - false.

OnClick

The virtual handler of control "Click" (mouse button click) internal event.

```
virtual bool OnClick()
```

Return Value

true - event processed, otherwise - false.

CPanel

CPanel is a class of the simple control based on "Rectangle label" chart object.

Description

CPanel class is intended to combine the controls with similar functions in the group.

Declaration

```
class CPanel : public CWndObj
```

Title

```
#include <Controls\Panel.mqh>
```

```

Create

Creates new CPanel control.

```
virtual bool Create(  
    const long   chart,      // chart ID  
    const string name,      // name  
    const int    subwin,    // chart subwindow  
    const int    x1,        // coordinate  
    const int    y1,        // coordinate  
    const int    x2,        // coordinate  
    const int    y2         // coordinate  
)
```

Parameters

chart

[in] ID of the chart, at which the control is created.

name

[in] Unique name of the control.

subwin

[in] Subwindow of the chart, at which the control is created.

x1

[in] X coordinate of the upper left corner.

y1

[in] Y coordinate of the upper left corner.

x2

[in] X coordinate of the lower right corner.

y2

[in] Y coordinate of the lower right corner.

Return Value

true - successful, otherwise - false.

BorderType (Get method)

Gets the "BorderType" property of the chart object.

```
ENUM_BORDER_TYPE BorderType()
```

Return Value

The value of "BorderType" property.

BorderType (Set method)

Sets new value of "BorderType" property of the chart object.

```
bool BorderType (  
    const ENUM_BORDER_TYPE type // value  
)
```

Parameters

type

[in] New value of "BorderType" property.

Return Value

true - successful, otherwise - false.

OnSetText

The virtual handler of control "SetText" (change of the [OBJPROP_TEXT](#) property) event.

```
virtual bool OnSetText()
```

Return Value

true - event processed, otherwise - false.

OnSetColorBackground

The virtual handler of control "SetColorBackground" (change of the [OBJPROP_BGCOLOR](#) property) event.

```
virtual bool OnSetColorBackground()
```

Return Value

true - event processed, otherwise - false.

OnSetColorBorder

The virtual handler of control "SetColorBorder" (change of the [OBJPROP_BORDER_COLOR](#) property) event.

```
virtual bool OnSetColorBackground()
```

Return Value

true - event processed, otherwise - false.

OnCreate

The virtual handler of control "Create" internal event.

```
virtual bool OnCreate()
```

Return Value

true - event processed, otherwise - false.

OnShow

The virtual handler of control "Show" internal event.

```
virtual bool OnShow()
```

Return Value

true - event processed, otherwise - false.

OnHide

The virtual handler of control "Hide" internal event.

```
virtual bool OnHide()
```

Return Value

true - event processed, otherwise - false.

OnMove

The virtual handler of control "Move" internal event.

```
virtual bool OnMove()
```

Return Value

true - event processed, otherwise - false.

OnResize

The virtual handler of control "Resize" internal event.

```
virtual bool OnResize()
```

Return Value

true - event processed, otherwise - false.

OnChange

The virtual handler of control "Change" internal event.

```
virtual bool OnChange()
```

Return Value

true - event processed, otherwise - false.

CPicture

CPicture is a class of the simple control based on "Bitmap Label" object.

Description

CPicture class is intended for creation of simple graphic images.

Declaration

```
class CPicture : public CWndObj
```

Title

```
#include <Controls\Picture.mqh>
```

Inheritance hierarchy

Result of the [code](#) provided below:

}

```

Create

Creates new CPicture control.

```
virtual bool Create(  
    const long    chart,      // chart ID  
    const string  name,      // name  
    const int     subwin,     // chart subwindow  
    const int     x1,        // coordinate  
    const int     y1,        // coordinate  
    const int     x2,        // coordinate  
    const int     y2         // coordinate  
)
```

Parameters

chart

[in] ID of the chart, at which the control is created.

name

[in] Unique name of the control.

subwin

[in] Subwindow of the chart, at which the control is created.

x1

[in] X coordinate of the upper left corner.

y1

[in] Y coordinate of the upper left corner.

x2

[in] X coordinate of the lower right corner.

y2

[in] Y coordinate of the lower right corner.

Return Value

true - successful, otherwise - false.

Border (Get method)

Gets the "Border" (border width) property of the control.

```
int Border() const
```

Return Value

The "Border" property.

Border (Set method)

Sets the "Border" (border width) property of the control.

```
bool Border(  
    const int value    // value  
)
```

Parameters

value

[in] New value of the "Border" property.

Return Value

true - successful, otherwise - false.

BmpName (Get method)

Gets the name of bmp file of the control.

```
string BmpName() const
```

Return Value

Name of bmp file of the control.

BmpName (Set method)

Sets the name of bmp file of the control.

```
bool BmpName (  
    const string name // file name  
)
```

Parameters

name

[in] Name of bmp file of the control.

Return Value

true - successful, otherwise - false.

OnCreate

The virtual handler of control "Create" internal event.

```
virtual bool OnCreate()
```

Return Value

true - event processed, otherwise - false.

OnShow

The virtual handler of control "Show" internal event.

```
virtual bool OnShow()
```

Return Value

true - event processed, otherwise - false.

OnHide

The virtual handler of control "Hide" internal event.

```
virtual bool OnHide()
```

Return Value

true - event processed, otherwise - false.

OnMove

The virtual handler of control "Move" internal event.

```
virtual bool OnMove()
```

Return Value

true - event processed, otherwise - false.

OnChange

The virtual handler of control "Change" internal event.

```
virtual bool OnChange()
```

Return Value

true - event processed, otherwise - false.

CScroll

CScroll is a base class for creation of scroll bars.

Description

CScroll is a complex control (with dependent controls), it contains the base functionality for creation of scroll bars. The base class itself is not used as a separate control, two of its heirs ([CScrollV](#) and [CScrollH](#) classes) are used as controls.

Declaration

```
class CScroll : public CWndContainer
```

Title

```
#include <Controls\Scrolls.mqh>
```

Inheritance hierarchy

[CObject](#)

[CWnd](#)

[CWndContainer](#)

CScroll

Direct descendants

[CScrollH](#), [CScrollV](#)

Class Methods by Groups

Create	
Create	Creates control
Chart object event handlers	
OnEvent	Event handler of all chart events
Properties	
MinPos	Gets/sets the minimal position
MaxPos	Gets/sets the maximal position
CurrPos	Gets/sets the current position
Dependent controls creation	
CreateBack	Creates background button
CreateInc	Creates increment button of the scroll bar
CreateDec	Creates decrement button of the scroll bar

CreateThumb	Creates thumb button (can be dragged) of the scroll bar
Dependent controls event handlers	
OnClickInc	Event handler used for handling increment button events
OnClickDec	Event handler used for handling decrement button events
Internal event handlers	
OnShow	"Create" internal event handler
OnHide	"Hide" internal event handler
OnChangePos	"ChangePosition" internal event handler
Object drag handlers	
OnThumbDragStart	"ThumbDragStart" event handler
OnThumbDragProcess	"ThumbDragProcess" event handler
OnThumbDragEnd	"ThumbDragEnd" event handler
Position	
CalcPos	Gets scroll bar position by coordinate

Methods inherited from class CObject

Prev, Prev, Next, Next, [Type](#), [Compare](#)

Methods inherited from class CWnd

[Name](#), [ControlsTotal](#), [Control](#), [Rect](#), [Left](#), [Left](#), [Top](#), [Top](#), [Right](#), [Right](#), [Bottom](#), [Bottom](#), [Width](#), [Width](#), [Height](#), [Height](#), [Size](#), [Size](#), [Size](#), [Contains](#), [Contains](#), [Alignment](#), [Align](#), [Id](#), [IsEnabled](#), [IsVisible](#), [Visible](#), [IsActive](#), [Activate](#), [Deactivate](#), [StateFlags](#), [StateFlags](#), [StateFlagsSet](#), [StateFlagsReset](#), [PropFlags](#), [PropFlags](#), [PropFlagsSet](#), [PropFlagsReset](#), [MouseX](#), [MouseX](#), [MouseY](#), [MouseY](#), [MouseFlags](#), [MouseFlags](#), [MouseFocusKill](#), [BringToTop](#)

Create

Creates new CScroll control.

```
virtual bool Create(  
    const long   chart,      // chart ID  
    const string name,      // name  
    const int    subwin,    // chart subwindow  
    const int    x1,        // coordinate  
    const int    y1,        // coordinate  
    const int    x2,        // coordinate  
    const int    y2        // coordinate  
)
```

Parameters

chart

[in] ID of the chart, at which the control is created.

name

[in] Unique name of the control.

subwin

[in] Subwindow of the chart, at which the control is created.

x1

[in] X coordinate of the upper left corner.

y1

[in] Y coordinate of the upper left corner.

x2

[in] X coordinate of the lower right corner.

y2

[in] Y coordinate of the lower right corner.

Return Value

true - successful, otherwise - false.

OnEvent

Chart event handler.

```
virtual bool OnEvent(  
    const int      id,           // ID  
    const long&    lparam,       // parameter  
    const double&  dparam,       // parameter  
    const string&  sparam        // parameter  
)
```

Parameters

id

[in] Event ID.

lparam

[in] Event parameter of [long](#) type passed by reference.

dparam

[in] Event parameter of [double](#) type passed by reference.

sparam

[in] Event parameter of [string](#) type passed by reference.

Return Value

true - event processed, otherwise - false.

MinPos (Get method)

Gets the value of "MinPos" (minimal position) of the CScroll control.

```
int MinPos() const
```

Return Value

New value of "MinPos" property.

MinPos (Set method)

Sets the value of "MinPos" (minimal position) of the CScroll control.

```
void MinPos(  
    const int value    // value  
)
```

Parameters

value

[in] New value of "MinPos" property.

Return Value

None.

MaxPos (Get method)

Gets the value of "MaxPos" (maximal position) of the CScroll control.

```
int MaxPos() const
```

Return Value

New value of "MaxPos" property.

MaxPos (Set method)

Sets the value of "MaxPos" (maximal position) of the CScroll control.

```
void MaxPos(  
    const int value    // value  
)
```

Parameters

value

[in] New value of "MaxPos" property.

Return Value

None.

CurrPos (Get method)

Gets the value of "CurrPos" (current position) of the CScroll control.

```
int CurrPos() const
```

Return Value

New value of "CurrPos" property.

CurrPos (Set method)

Sets the value of "CurrPos" (current position) of the CScroll control.

```
void CurrPos(  
    const int value    // value  
)
```

Parameters

value

[in] New value of "CurrPos" property.

Return Value

None.

CreateBack

Creates background button of the CScroll control.

```
virtual bool CreateBack()
```

Return Value

true - successful, otherwise - false.

CreateInc

Creates increment button of CScroll control.

```
virtual bool CreateInc()
```

Return Value

true - successful, otherwise - false.

CreateDec

Creates decrement button of CScroll control.

```
virtual bool CreateDec()
```

Return Value

true - successful, otherwise - false.

CreateThumb

Creates thumb button (can be dragged) of CScroll control.

```
virtual bool CreateThumb()
```

Return Value

true - successful, otherwise - false.

OnClickInc

The virtual handler of the control "ClickInc" (left mouse button click on the increment button) internal event.

```
virtual bool OnClickInc()
```

Return Value

true - event processed, otherwise - false.

OnClickDec

The virtual handler of the control "ClickDec" (left mouse button click on the decrement button) internal event.

```
virtual bool OnClickDec()
```

Return Value

true - event processed, otherwise - false.

OnShow

The virtual handler of the control "Show" event.

```
virtual bool OnShow()
```

Return Value

true - event processed, otherwise - false.

OnHide

The virtual handler of the control "Hide" internal event.

```
virtual bool OnHide()
```

Return Value

true - event processed, otherwise - false.

OnChangePos

The virtual handler of the control "ChangePos" (position change) internal event.

```
virtual bool OnChangePos()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.

OnThumbDragStart

The virtual handler of the control "ThumbDragStart" (drag start) event.

```
virtual bool OnThumbDragStart ()
```

Return Value

true - event processed, otherwise - false.

Note

The "ThumbDragStart" event occurs at start of the drag operation.

OnThumbDragProcess

The virtual handler of the control "ThumbDragProcess" event.

```
virtual bool OnThumbDragProcess(  
    const int x,      // x coordinate  
    const int y      // y coordinate  
)
```

Parameters

x

[in] Current X coordinate of mouse cursor.

y

[in] Current Y coordinate of mouse cursor.

Return Value

true - event processed, otherwise - false.

Note

The "ThumbDragProcess" occurs when the scroll bar control (thumb button) is moved.

OnThumbDragEnd

The virtual handler of the control "ThumbDragEnd" (drag process finished) event.

```
virtual bool OnThumbDragEnd()
```

Return Value

true - event processed, otherwise - false.

Note

The "ThumbDragEnd" occurs when the drag operation of the scroll bar control (thumb button) is finished.

CalcPos

Gets the control scroll bar position by coordinate.

```
virtual int CalcPos(  
    const int coord // coordinate  
)
```

Parameters

coord

[in] Scroll bar coordinate.

Return Value

Scroll bar position.

CScrollV

CScrollV is a class of the "Vertical scroll bar" complex control.

Description

CScrollV class is intended for creation of vertical scroll bars.

Declaration

```
class CScrollV : public CScroll
```

Title

```
#include <Controls\Scrolls.mqh>
```

Inheritance hierarchy

CreateThumb	Creates scroll bar thumb button (can be dragged)
Internal event handlers	
OnResize	"Resize" internal event handler
OnChangePos	"ChangePosition" internal event handler
Drag event handlers	
OnThumbDragStart	"ThumbDragStart" event handler
OnThumbDragProcess	"ThumbDragProcess" event handler
OnThumbDragEnd	"ThumbDragEnd" event handler
Position	
CalcPos	Gets scroll bar position by coordinate

        const double& dparam, // event parameter of the double type
        const string& sparam) // event parameter of the string type
{
    ExtDialog.ChartEvent(id,lparam,dparam,sparam);
}
```

CreateInc

Creates increment button of the control.

```
virtual bool CreateInc()
```

Return Value

true - successful, otherwise - false.

CreateDec

Creates decrement button of the control.

```
virtual bool CreateDec()
```

Return Value

true - successful, otherwise - false.

CreateThumb

Creates thumb button (can be dragged) of the control.

```
virtual bool CreateThumb()
```

Return Value

true - successful, otherwise - false.

OnResize

The virtual handler of the control "Resize" internal event.

```
virtual bool OnResize()
```

Return Value

true - event processed, otherwise - false.

OnChangePos

The virtual handler of the control "ChangePos" (position change) internal event.

```
virtual bool OnChangePos()
```

Return Value

true - event processed, otherwise - false.

OnThumbDragStart

The virtual handler of the control "ThumbDragStart" (drag start) event.

```
virtual bool OnThumbDragStart ()
```

Return Value

true - event processed, otherwise - false.

Note

The "ThumbDragStart" event occurs at start of the drag operation.

OnThumbDragProcess

The virtual handler of the control "ThumbDragProcess" event.

```
virtual bool OnThumbDragProcess(  
    const int x,      // x coordinate  
    const int y      // y coordinate  
)
```

Parameters

x

[in] Current X coordinate of mouse cursor.

y

[in] Current Y coordinate of mouse cursor.

Return Value

true - event processed, otherwise - false.

Note

The "ThumbDragProcess" occurs when the scroll bar control (thumb button) is moved.

OnThumbDragEnd

The virtual handler of the control "ThumbDragEnd" (drag process finished) event.

```
virtual bool OnThumbDragEnd()
```

Return Value

true - event processed, otherwise - false.

Note

The "ThumbDragEnd" occurs when the drag operation of the scroll bar control (thumb button) is finished.

CalcPos

Gets the control scroll bar position by coordinate.

```
virtual int CalcPos(  
    const int coord // coordinate  
)
```

Parameters

coord

[in] Scroll bar coordinate.

Return Value

Scroll bar position.

CScrollH

CScrollH is a class of the "Horizontal scroll bar" complex control.

Description

CScrollH is intended for creation of horizontal scroll bars.

Declaration

```
class CScrollH : public CScroll
```

Title

```
#include <Controls\Scrolls.mqh>
```

}
```

CreateInc

Creates increment button of the control.

```
virtual bool CreateInc()
```

Return Value

true - successful, otherwise - false.

CreateDec

Creates decrement button of the control.

```
virtual bool CreateDec()
```

Return Value

true - successful, otherwise - false.

CreateThumb

Creates thumb button (can be dragged) of the control.

```
virtual bool CreateThumb()
```

Return Value

true - successful, otherwise - false.

OnResize

The virtual handler of the control "Resize" internal event.

```
virtual bool OnResize()
```

Return Value

true - event processed, otherwise - false.

OnChangePos

The virtual handler of the control "ChangePos" (position change) internal event.

```
virtual bool OnChangePos()
```

Return Value

true - event processed, otherwise - false.

OnThumbDragStart

The virtual handler of the control "ThumbDragStart" (drag start) event.

```
virtual bool OnThumbDragStart ()
```

Return Value

true - event processed, otherwise - false.

Note

The "ThumbDragStart" event occurs at start of the drag operation.

OnThumbDragProcess

The virtual handler of the control "ThumbDragProcess" event.

```
virtual bool OnThumbDragProcess(  
    const int x,      // x coordinate  
    const int y      // y coordinate  
)
```

Parameters

x

[in] Current X coordinate of mouse cursor.

y

[in] Current Y coordinate of mouse cursor.

Return Value

true - event processed, otherwise - false.

Note

The "ThumbDragProcess" occurs when the scroll bar control (thumb button) is moved.

OnThumbDragEnd

The virtual handler of the control "ThumbDragEnd" (drag process finished) event.

```
virtual bool OnThumbDragEnd()
```

Return Value

true - event processed, otherwise - false.

Note

The "ThumbDragEnd" occurs when the drag operation of the scroll bar control (thumb button) is finished.

CalcPos

Gets the control scroll bar position by coordinate.

```
virtual int CalcPos(  
    const int coord // coordinate  
)
```

Parameters

coord

[in] Scroll bar coordinate.

Return Value

Scroll bar position.

CWndClient

CWndClient is a class of the "Client area" complex control (with dependent controls). It is a base class for creation of scroll bars area.

Description

CWndClient implements the functionality for creation of client area with scroll bars.

Declaration

```
class CWndClient : public CWndContainer
```

Title

```
#include <Controls\WndClient.mqh>
```

Inheritance hierarchy

Class Methods by Groups

Create	
Create	Creates control
Chart event handler	
OnEvent	Event handler of all chart events
Properties	
ColorBackground	Sets background color
ColorBorder	Sets border color
BorderType	Sets border type
Settings	
VScrolled	Gets/sets the flag indicating that vertical scroll bar is used
HScrolled	Gets/sets the flag indicating that horizontal scroll bar is used
Dependent controls	

CreateBack	Creates background for scroll bar
CreateScrollV	Creates vertical scroll bar
CreateScrollH	Creates horizontal scroll bar
Internal event handlers	
OnResize	"Resize" internal event handler
Dependent controls event handlers	
OnVScrollShow	"Show" internal event handler (virtual) of VScroll dependent control
OnVScrollHide	"Hide" internal event handler (virtual) of VScroll dependent control
OnHScrollShow	"Show" internal event handler (virtual) of HScroll dependent control
OnHScrollHide	"Hide" internal event handler (virtual) of HScroll dependent control
OnScrollLineDown	"ScrollLineDown" internal event handler (virtual) of VScroll dependent control
OnScrollLineUp	"ScrollLineUp" internal event handler (virtual) of VScroll dependent control
OnScrollLineLeft	"ScrollLineLeft" internal event handler (virtual) of HScroll dependent control
OnScrollLineRight	"ScrollLineRight" internal event handler (virtual) of HScroll dependent control
Resize	
Rebound	Sets new parameters of the control using CRect class coordinates

Methods inherited from class CObject

Prev, Prev, Next, Next, [Type](#), [Compare](#)

Create

Creates new CWndClient control.

```
virtual bool Create(  
    const long    chart,      // chart ID  
    const string  name,      // name  
    const int     subwin,     // chart subwindow  
    const int     x1,         // coordinate  
    const int     y1,         // coordinate  
    const int     x2,         // coordinate  
    const int     y2         // coordinate  
)
```

Parameters

chart

[in] ID of the chart, at which the control is created.

name

[in] Unique name of the control.

subwin

[in] Subwindow of the chart, at which the control is created.

x1

[in] X coordinate of the upper left corner.

y1

[in] Y coordinate of the upper left corner.

x2

[in] X coordinate of the lower right corner.

y2

[in] Y coordinate of the lower right corner.

Return Value

true - successful, otherwise - false.

OnEvent

Chart event handler.

```
virtual bool OnEvent(  
    const int      id,           // ID  
    const long&    lparam,      // parameter  
    const double&  dparam,      // parameter  
    const string&  sparam       // parameter  
)
```

Parameters

id

[in] Event ID.

lparam

[in] Event parameter of [long](#) type passed by reference.

dparam

[in] Event parameter of [double](#) type passed by reference.

sparam

[in] Event parameter of [string](#) type passed by reference.

Return Value

true - event processed, otherwise - false.

ColorBackground

Sets background color of the control.

```
bool ColorBackground(  
    const color value    // background color  
)
```

Parameters

value

[in] Background color of the control.

Return Value

true - successful, otherwise - false.

ColorBorder

Set border color of the control.

```
bool ColorBorder(  
    const color value    // color  
)
```

Parameters

value

[in] Border color of the control.

Return Value

true - successful, otherwise - false.

BorderStyle

Sets border type of the control.

```
bool BorderType(  
    const ENUM_BORDER_TYPE type // value  
)
```

Parameters

type

[in] Border type of the control.

Return Value

true - successful, otherwise - false.

VScrolled (Get method)

Gets the flag indicating that vertical scroll bar is used.

```
bool VScrolled()
```

Return Value

true - vertical scroll bar is used, otherwise - false.

VScrolled (Set method)

Sets the flag indicating that vertical scroll bar is used.

```
bool VScrolled(  
    const bool flag    // flag  
)
```

Parameters

flag

[in] Flag.

Return Value

true - successful, otherwise - false.

HScrolled (Get method)

Gets the flag indicating that horizontal scroll bar is used.

```
bool HScrolled()
```

Return Value

true - horizontal scroll bar is used, otherwise - false.

HScrolled (Set method)

Sets the flag indicating that horizontal scroll bar is used.

```
bool HScrolled(  
    const bool flag    // flag  
)
```

Parameters

flag

[in] Flag.

Return Value

true - successful, otherwise - false.

CreateBack

Creates background button of the control.

```
virtual bool CreateBack()
```

Return Value

true - successful, otherwise - false.

CreateScrollV

Creates vertical scroll bar.

```
virtual bool CreateScrollV()
```

Return Value

true - successful, otherwise - false.

CreateScrollH

Creates horizontal scroll bar.

```
virtual bool CreateScrollH()
```

Return Value

true - successful, otherwise - false.

OnResize

The virtual handler of the control "Resize" internal event.

```
virtual bool OnResize()
```

Return Value

true - event processed, otherwise - false.

OnVScrollShow

The virtual handler of the VScroll (vertical scroll) dependent control "Show" (vertical scroll bar show) internal event.

```
virtual bool OnVScrollShow()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.

OnVScrollHide

The virtual handler of the VScroll (vertical scroll) dependent control "Hide" (vertical scroll bar hide) internal event.

```
virtual bool OnVScrollHide()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.

OnHScrollShow

The virtual handler of the HScroll (horizontal scroll) dependent control "Show" (horizontal scroll bar show) internal event.

```
virtual bool OnHScrollShow()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.

OnHScrollHide

The virtual handler of the HScroll (horizontal scroll) dependent control "Hide" (horizontal scroll bar hide) internal event.

```
virtual bool OnHScrollHide()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.

OnScrollLineDown

The virtual handler of the VScroll (vertical scroll) dependent control "ScrollLineDown" (vertical scroll line down) internal event.

```
virtual bool OnScrollLineDown()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.

OnScrollLineUp

The virtual handler of the VScroll (vertical scroll) dependent control "ScrollLineUp" (vertical scroll line up) internal event.

```
virtual bool OnScrollLineUp()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.

OnScrollLineLeft

The virtual handler of the HScroll (horizontal scroll) dependent control "ScrollLineLeft" (horizontal scroll line left) internal event.

```
virtual bool OnScrollLineLeft()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.

OnScrollLineRight

The virtual handler of the HScroll (horizontal scroll) dependent control "ScrollLineRight" (horizontal scroll line right) internal event.

```
virtual bool OnScrollLineRight()
```

Return Value

true - event processed, otherwise - false.

Note

The base class method does nothing and always returns true.

ReBound

Sets new parameters of the control using CRect class coordinates.

```
void ReBound(  
    const & CRect rect    // CRect class  
)
```

Return Value

None.

CListView

CListView is a class of the ListView complex control (with dependent controls).

Description

CListView class encapsulates list-control functionality.

Declaration

```
class CListView : public CWndClient
```

Title

```
#include <Controls\ListView.mqh>
```

Inheritance hierarchy

[CObject](#)

[CWnd](#)

[CWndContainer](#)

[CWndClient](#)

CListView

Result of the [code](#) provided below:

Class Methods by Groups

Create

Create	Creates control
Chart event handlers	
OnEvent	Event handler of all chart events
Settings	
TotalView	Sets the number of items shown on the control
Add/Delete	
AddItem	Adds an item to control list
Data	
Select	Selects current list element by index
SelectByText	Selects current list element by text
SelectByValue	Selects current list element by value
Read-only data	
Value	Gets the value of the current list element
Dependent controls	
CreateRow	Creates a row of the ListView
Internal event handlers	
OnResize	"Resize" internal event handler (virtual)
Dependent controls event handlers	
OnVScrollShow	"Show" internal event handler (virtual) of VScroll dependent control
OnVScrollHide	"Hide" internal event handler (virtual) of VScroll dependent control
OnScrollLineDown	"ScrollLineDown" internal event handler (virtual) of VScroll dependent control
OnScrollLineUp	"ScrollLineUp" internal event handler (virtual) of VScroll dependent control
OnItemClick	"ItemClick" internal event handler (virtual)
Redraw	
Redraw	Redraws the control
RowState	Sets the state of the specified row
CheckView	Checks the "visibility" of the specified row

}
```

Create

Creates CListView control.

```
virtual bool Create(  
    const long    chart,      // chart ID  
    const string  name,      // name  
    const int     subwin,     // chart subwindow  
    const int     x1,        // coordinate  
    const int     y1,        // coordinate  
    const int     x2,        // coordinate  
    const int     y2         // coordinate  
)
```

Parameters

chart

[in] ID of the chart, at which the control is created.

name

[in] Unique name of the control.

subwin

[in] Subwindow, at which the control is created.

x1

[in] X coordinate of the upper left corner.

y1

[in] Y coordinate of the upper left corner.

x2

[in] X coordinate of the lower right corner.

y2

[in] Y coordinate of the lower right corner.

Return Value

true - successful, otherwise - false.

OnEvent

Chart event handler.

```
virtual bool OnEvent(  
    const int      id,           // ID  
    const long&    lparam,       // parameter  
    const double&  dparam,       // parameter  
    const string&  sparam        // parameter  
)
```

Parameters

id

[in] Event ID.

lparam

[in] Event parameter of [long](#) type passed by reference.

dparam

[in] Event parameter of [double](#) type passed by reference.

sparam

[in] Event parameter of [string](#) type passed by reference.

Return Value

true - event processed, otherwise - false.

TotalView

Sets the number of items shown on the control.

```
bool TotalView(  
    const int value    // number of items shown  
)
```

Parameters

value

[in] The number of items shown on the control.

Return Value

true - successful, otherwise - false.

Note

The number of shown items can be specified only at once.

AddItem

Adds an item to the control list.

```
bool AddItem(  
    const string item,      // text  
    const long  value      // value  
)
```

Parameters

item

[in] Text.

value

[in] Value.

Return Value

true - successful, otherwise - false.

Select

Selects current list element by index.

```
bool Select(  
    const int index    // index  
)
```

Parameters

index

[in] Item index.

Return Value

true - successful, otherwise - false.

SelectByText

Selects the current list element by text.

```
bool SelectByText(  
    const string text    // text  
)
```

Parameters

text

[in] Element text.

Return Value

true - successful, otherwise - false.

SelectByValue

Selects the current list element by value.

```
bool SelectByValue(  
    const long value    // value  
)
```

Parameters

value

[in] Value.

Return Value

true - successful, otherwise - false.

Value

Gets the value of the current list element.

```
long Value()
```

Return Value

The value of the current list element.

CreateRow

Creates a row of the CListView control.

```
bool CreateRow(  
    const int index    // index  
)
```

Parameters

index

[in] Item index.

Return Value

true - successful, otherwise - false.

OnResize

The virtual handler of the control "Resize" internal event.

```
virtual bool OnResize()
```

Return Value

true - event processed, otherwise - false.

OnVScrollShow

The virtual handler of the VScroll (vertical scroll) dependent control "VScrollShow" (vertical scroll bar show) internal event.

```
virtual bool OnVScrollShow()
```

Return Value

true - event processed, otherwise - false.

OnVScrollHide

The virtual handler of the VScroll (vertical scroll) dependent control "VScrollHide" (vertical scroll bar hide) internal event.

```
virtual bool OnVScrollHide()
```

Return Value

true - event processed, otherwise - false.

OnScrollLineDown

The virtual handler of the VScroll (vertical scroll) dependent control "ScrollLineDown" (vertical scroll line down) internal event.

```
virtual bool OnScrollLineDown()
```

Return Value

true - event processed, otherwise - false.

OnScrollLineUp

The virtual handler of the VScroll (vertical scroll) dependent control "ScrollLineUp" (vertical scroll line up) internal event.

```
virtual bool OnScrollLineUp()
```

Return Value

true - event processed, otherwise - false.

OnItemClick

The virtual handler of "ItemClick" (mouse button click) internal event on a specified row of CListView control.

```
virtual bool OnItemClick()  
    const int    index    // index  
    )
```

Return Value

true - event processed, otherwise - false.

Redraw

Redraws the control.

```
bool Redraw()
```

Return Value

true - successful, otherwise - false.

RowState

Changes the state of the specified row of the CListView control.

```
bool RowState(  
    const int    index        // index  
    const bool   select       // state  
)
```

Parameters

index

[in] Row index.

select

[in] Row state.

Return Value

true - successful, otherwise - false.

CheckView

Checks the "visibility" of the specified row of the CListView control.

```
bool CheckView()
```

Return Value

true - selected row is visible, otherwise - false.

CComboBox

CComboBox is a class of the ComboBox complex control (with dependent controls).

Description

ComboBox consists of a list box, combined with a static control, intended for selection. The list-box portion of the control may be dropped down when a user selects the drop-down arrow next to the control

Declaration

```
class CComboBox : public CWndContainer
```

Title

```
#include <Controls\ComboBox.mqh>
```

        ExtDialog.ChartEvent(id,lparam,dparam,sparam);  
    }
```

Create

Creates CComboBox control.

```
virtual bool Create(  
    const long    chart,      // chart ID  
    const string  name,      // name  
    const int     subwin,     // chart subwindow  
    const int     x1,        // coordinate  
    const int     y1,        // coordinate  
    const int     x2,        // coordinate  
    const int     y2         // coordinate  
)
```

Parameters

chart

[in] ID of the chat, at which the control is created.

name

[in] Unique name of the control.

subwin

[in] Subwindow of the chart, at which the control is created.

x1

[in] X coordinate of the upper left corner.

y1

[in] Y coordinate of the upper left corner.

x2

[in] X coordinate of the lower right corner.

y2

[in] Y coordinate of the lower right corner.

Return Value

true - successful, otherwise - false.

OnEvent

Chart event handler.

```
virtual bool OnEvent(  
    const int      id,           // ID  
    const long&    lparam,       // parameter  
    const double&  dparam,       // parameter  
    const string&  sparam        // parameter  
)
```

Parameters

id

[in] Event ID.

lparam

[in] Event parameter of [long](#) type passed by reference.

dparam

[in] Event parameter of [double](#) type passed by reference.

sparam

[in] Event parameter of [string](#) type passed by reference.

Return Value

true - event processed, otherwise - false.

AddItem

Adds an item to the control.

```
bool AddItem(  
    const string item,      // text  
    const long  value      // value  
)
```

Parameters

item

[in] Text.

value=0

[in] Value.

Return Value

true - successful, otherwise - false.

ListViewItems

Sets the number of list elements of the CComboBox control.

```
void ListViewItems(  
    const int    value    // number of elements  
)
```

Parameters

value

[in] Number of the drop-down list elements.

Return Value

true - successful, otherwise - false.

Select

Selects the current list element by index.

```
bool Select(  
    const int index    // index  
)
```

Parameters

index

[in] Item index.

Return Value

true - successful, otherwise - false.

SelectByText

Selects the current list element by a specified text.

```
bool SelectByText(  
    const string text    // text  
)
```

Parameters

text

[in] Text of the item.

Return Value

true - successful, otherwise - false.

SelectByValue

Selects the current list element by a specified value.

```
bool SelectByValue(  
    const long value    // value  
)
```

Parameters

value

[in] Value.

Return Value

true - successful, otherwise - false.

Value

Gets the value of the current list element.

```
long Value()
```

Return Value

The value of the current list element.

CreateEdit

Creates dependent control (edit) of the control.

```
virtual bool CreateEdit()
```

Return Value

true - successful, otherwise - false.

CreateButton

Creates dependent control (button).

```
virtual bool CreateButton()
```

Return Value

true - successful, otherwise - false.

CreateList

Creates dependent control (list view).

```
virtual bool CreateList()
```

Return Value

true - successful, otherwise - false.

OnClickEdit

The virtual handler of the control "ClickEdit" (mouse click on the edit) internal event.

```
virtual bool OnClickEdit()
```

Return Value

true - event processed, otherwise - false.

OnClickButton

The virtual handler of the "ClickButton" (mouse click on the button) internal event.

```
virtual bool OnClickButton()
```

Return Value

true - event processed, otherwise - false.

OnChangeList

The virtual handler of the "ChangeList" (change of the list) internal event.

```
virtual bool OnChangeList()
```

Return Value

true - event processed, otherwise - false.

ListShow

Shows the drop-down list of the control.

```
virtual bool ListShow()
```

Return Value

true - successful, otherwise - false.

ListHide

Hides the drop-down list of the control.

```
virtual bool ListHide()
```

Return Value

true - successful, otherwise - false.

CCheckBox

CCheckBox is class of the CheckBox complex control.

Description

CCheckBox control displays a check box that allows a user to select a true or false condition at a mouse click.

Declaration

```
class CCheckBox : public CWndContainer
```

Title

```
#include <Controls\CheckBox.mqh>
```

Class Methods by Groups

Create

Create	Creates control
Chart event handlers	
OnEvent	Event handler of all chart events
Properties	
Text	Gets/sets text label associated with the control
Color	Gets/sets color of text label associated with the control
State	
Checked	Gets/sets a value indicating whether the control is checked
Data	
Value	Gets/sets the value associated with the control
Dependent controls	
CreateButton	Creates dependent control (button)
CreateLabel	Creates dependent control (label)
Dependent controls event handlers	
ClickButton	"ClickButton" internal event handler (virtual)
ClickLabel	"ClickLabel" internal event handler (virtual)

}

```

Create

Creates CCheckBox control.

```
virtual bool Create(  
    const long    chart,      // chart ID  
    const string  name,      // name  
    const int     subwin,    // chart subwindow  
    const int     x1,        // coordinate  
    const int     y1,        // coordinate  
    const int     x2,        // coordinate  
    const int     y2        // coordinate  
)
```

Parameters

chart

[in] ID of the chart, at which the control is created.

name

[in] Unique name of the control.

subwin

[in] Subwindow of the chart, at which the control is created.

x1

[in] X coordinate of the upper left corner.

y1

[in] Y coordinate of the upper left corner.

x2

[in] X coordinate of the lower right corner.

y2

[in] Y coordinate of the lower right corner.

Return Value

true - successful, otherwise - false.

OnEvent

Chart event handler.

```
virtual bool OnEvent(  
    const int      id,           // ID  
    const long&    lparam,       // parameter  
    const double&  dparam,       // parameter  
    const string&  sparam        // parameter  
)
```

Parameters

id

[in] Event ID.

lparam

[in] Event parameter of [long](#) type passed by reference.

dparam

[in] Event parameter of [double](#) type passed by reference.

sparam

[in] Event parameter of [string](#) type passed by reference.

Return Value

true - event processed, otherwise - false.

Text (Get method)

Gets text of the label associated with the control.

```
string Text()
```

Return Value

Text of the label.

Text (Set method)

Sets text of the label associated with the control.

```
bool Text(  
    const string value    // text  
)
```

Parameters

value

[in] New text of the label.

Return Value

true - successful, otherwise - false.

Note

Label text is specified by setting [OBJPROP_TEXT](#) (text) of a chart object.

Color (Get method)

Gets color of the label associated with the control.

```
color Color() const
```

Return Value

Label color.

Color (Set method)

Sets color of the label associated with the control.

```
bool Color(  
    const color value    // color  
)
```

Parameters

value

[in] New label color.

Return Value

true - successful, otherwise - false.

Note

Label color is specified by setting [OBJPROP_COLOR](#) (color) of a chart object.

Checked (Get method)

Gets state of the control.

```
bool Checked() const
```

Return Value

State of the control.

Checked (Set method)

Sets state of the control.

```
bool Checked(  
    const bool flag    // state  
)
```

Parameters

flag

[in] New state.

Return Value

true - successful, otherwise - false.

Value (Get method)

Gets the value associated with the control.

```
int Value() const
```

Return Value

The value associated with the control.

Value (Set method)

Sets the value associated with the control.

```
void Value(  
    const int value    // value  
)
```

Parameters

value

[in] New value.

Return Value

None.

CreateButton

Creates dependent control (button).

```
virtual bool CreateButton()
```

Return Value

true - successful, otherwise - false.

CreateLabel

Creates dependent control (label).

```
virtual bool CreateLabel()
```

Return Value

true - successful, otherwise - false.

OnClickButton

The virtual handler of the control "ClickButton" (mouse click on the button) internal event.

```
virtual bool OnClickButton()
```

Return Value

true - event processed, otherwise - false.

OnClickLabel

The virtual handler of the control "ClickLabel" (mouse click on the label) internal event.

```
virtual bool OnClickLabel ()
```

Return Value

true - event processed, otherwise - false.

CCheckGroup

CCheckGroup is a class of the CheckGroup complex control (with dependent controls).

Description

CCheckGroup provides the possibility for creation of controls, which allow to display and edit flags.

Declaration

```
class CCheckGroup : public CWndClient
```

Title

```
#include <Controls\CheckGroup.mqh>
```

Inheritance hierarchy

CCheckGroup

Result of the [code](#) provided below:

Class Methods by Groups

Create

Create	Creates control
Chart event handlers	
OnEvent	Event handler for all chart events
Add	
AddItem	Adds new item
Read-only data	
Value	Gets the value associated with the control
Dependent controls	
CreateButton	Creates new CCheckBox item at a specified index
Dependent controls event handlers	
OnVScrollShow	"Show" internal event handler (virtual) of VScroll dependent control
OnVScrollHide	"Hide" internal event handler (virtual) of VScroll dependent control
OnScrollLineDown	"ScrollLineUp" internal event handler (virtual) of VScroll dependent control
OnScrollLineUp	"ScrollLineDown" internal event handler (virtual) of VScroll dependent control
OnChangeItem	"ChangeItem" internal event handler (virtual) of VScroll dependent control
Redraw	
Redraw	Redraws the group
RowState	Sets the state of the specified item of the group

                  const string& sparam) // event parameter of the string type
{
    ExtDialog.ChartEvent(id,lparam,dparam,sparam);
}
```

Create

Creates new CCheckGroup control.

```
virtual bool Create(  
    const long    chart,      // chart ID  
    const string  name,      // name  
    const int     subwin,     // chart subwindow  
    const int     x1,        // coordinate  
    const int     y1,        // coordinate  
    const int     x2,        // coordinate  
    const int     y2         // coordinate  
)
```

Parameters

chart

[in] ID of the chart, at which the control is created.

name

[in] Unique name of the control.

subwin

[in] Subwindow of the chart, at which the control is created.

x1

[in] X coordinate of the upper left corner.

y1

[in] Y coordinate of the upper left corner.

x2

[in] X coordinate of the lower right corner.

y2

[in] Y coordinate of the lower right corner.

Return Value

true - successful, otherwise - false.

OnEvent

Chart event handler.

```
virtual bool OnEvent(  
    const int      id,           // ID  
    const long&    lparam,       // parameter  
    const double&  dparam,       // parameter  
    const string&  sparam        // parameter  
)
```

Parameters

id

[in] Event ID.

lparam

[in] Event parameter of [long](#) type passed by reference.

dparam

[in] Event parameter of [double](#) type passed by reference.

sparam

[in] Event parameter of [string](#) type passed by reference.

Return Value

true - event processed, otherwise - false.

AddItem

Adds an item (row) to the control.

```
bool AddItem(  
    const string item,      // text  
    const long  value      // value  
)
```

Parameters

item

[in] Added control label text.

value=0

[in] Value associated with the added control.

Return Value

true - successful, otherwise - false.

Value

Gets the value associated with the control.

```
long Value()
```

Return Value

The value associated with the control.

Note

The value depends on state of all items of the CCheckGroup.

CreateButton

Creates new CCheckBox class instance at a specified index.

```
bool CreateButton(  
    int index    // index  
)
```

Parameters

index

[in] Index of the new item in the CCheckGroup.

Return Value

true - successful, otherwise - false.

OnVScrollShow

The virtual handler of the dependent VScroll (vertical scroll) control "Show" internal event.

```
virtual bool OnVScrollShow()
```

Return Value

true - event processed, otherwise - false.

OnVScrollHide

The virtual handler of the dependent VScroll (vertical scroll) control "Hide" internal event.

```
virtual bool OnVScrollHide()
```

Return Value

true - event processed, otherwise - false.

OnScrollLineDown

The virtual handler of the dependent VScroll (vertical scroll) control "ScrollLineDown" internal event.

```
virtual bool OnScrollLineDown ()
```

Return Value

true - event processed, otherwise - false.

OnScrollLineUp

The virtual handler of the dependent VScroll (vertical scroll) control "ScrollLineUp" internal event.

```
virtual bool OnScrollLineUp()
```

Return Value

true - event processed, otherwise - false.

OnChangeItem

The virtual handler of the control "ChangeItem" (item change) internal event.

```
virtual bool OnChangeItem(  
    const int index    // index  
)
```

Parameters

index

[in] Index of the changed item.

Return Value

true - event processed, otherwise - false.

Redraw

Redraws the control.

```
bool Redraw()
```

Return Value

true - successful, otherwise - false.

RowState

Sets the state of the specified item.

```
bool RowState(  
    const int    index,      // item index  
    const bool   select      // state  
)
```

Parameters

index

[in] Item index to change.

select

[in] New state.

Return Value

true - successful, otherwise - false.

CRadioButton

CRadioButton is a class of RadioButton complex control.

Description

CRadioButton itself is not used, it used for creation of [CRadioGroup](#) items.

Declaration

```
class CRadioButton : public CWndContainer
```

Title

```
#include <Controls\RadioButton.mqh>
```

Inheritance hierarchy

[CObject](#)

[CWnd](#)

[CWndContainer](#)

CRadioButton

Class Methods by Groups

Create	
Create	Creates control
Chart event handlers	
OnEvent	Event handler for all chart events
Properties	
Text	Gets/sets the text label associated with the control
Color	Gets/sets the color of text label associated with the control
State	
State	Gets/sets the state
Dependent controls	
CreateButton	Creates button
CreateLabel	Creates label
Dependent controls event handlers	
OnClickButton	"ClickButton" internal event handler (virtual)
OnClickLabel	"ClickLabel" internal event handler (virtual)

Methods inherited from class CObject

Prev, Prev, Next, Next, [Type](#), [Compare](#)

Methods inherited from class CWnd

[Name](#), [ControlsTotal](#), [Control](#), [Rect](#), [Left](#), [Left](#), [Top](#), [Top](#), [Right](#), [Right](#), [Bottom](#), [Bottom](#), [Width](#), [Width](#), [Height](#), [Height](#), [Size](#), [Size](#), [Size](#), [Contains](#), [Contains](#), [Alignment](#), [Align](#), [Id](#), [IsEnabled](#), [IsVisible](#), [Visible](#), [IsActive](#), [Activate](#), [Deactivate](#), [StateFlags](#), [StateFlags](#), [StateFlagsSet](#), [StateFlagsReset](#), [PropFlags](#), [PropFlags](#), [PropFlagsSet](#), [PropFlagsReset](#), [MouseX](#), [MouseX](#), [MouseY](#), [MouseY](#), [MouseFlags](#), [MouseFlags](#), [MouseFocusKill](#), [BringToTop](#)

Methods inherited from class CWndContainer

[Destroy](#), [OnMouseEvent](#), [ControlsTotal](#), [Control](#), [ControlFind](#), [MouseFocusKill](#), [Add](#), [Add](#), [Delete](#), [Delete](#), [Move](#), [Move](#), [Shift](#), [Id](#), [Enable](#), [Disable](#), [Show](#), [Hide](#), [Save](#), [Load](#)

Create

Creates new CRadioButton control.

```
virtual bool Create(  
    const long    chart,      // chart ID  
    const string  name,      // name  
    const int     subwin,     // chart subwindow  
    const int     x1,        // coordinate  
    const int     y1,        // coordinate  
    const int     x2,        // coordinate  
    const int     y2         // coordinate  
)
```

Parameters

chart

[in] ID of the chart, at which the control is created.

name

[in] Unique name of the control.

subwin

[in] Subwindow of the chart, at which the control is created.

x1

[in] X coordinate of the upper left corner.

y1

[in] Y coordinate of the upper left corner.

x2

[in] X coordinate of the lower right corner.

y2

[in] Y coordinate of the lower right corner.

Return Value

true - successful, otherwise - false.

OnEvent

Chart event handler.

```
virtual bool OnEvent(  
    const int      id,           // ID  
    const long&    lparam,      // parameter  
    const double&  dparam,      // parameter  
    const string&  sparam       // parameter  
)
```

Parameters

id

[in] Event ID.

lparam

[in] Event parameter of [long](#) type passed by reference.

dparam

[in] Event parameter of [double](#) type passed by reference.

sparam

[in] Event parameter of [string](#) type passed by reference.

Return Value

true - event processed, otherwise - false.

Text (Get method)

Gets text of the label associated with the control.

```
string Text()
```

Return Value

Text of the label.

Text (Set method)

Sets text of the label.

```
bool Text(  
    const string value    // text  
)
```

Parameters

value

[in] New text of the label.

Return Value

true - successful, otherwise - false.

Color (Get method)

Gets color of the label associated with the control.

```
color Color() const
```

Return Value

Label color.

Color (Set method)

Sets color of the label associated with the control.

```
bool Color(  
    const color value    // color  
)
```

Parameters

value

[in] New label color.

Return Value

true - successful, otherwise - false.

State (Get method)

Gets the button state.

```
bool State() const
```

Return Value

Button state.

State (Set method)

Sets the button state.

```
bool State(  
    const bool flag    // flag  
)
```

Parameters

flag

[in] New button state.

Return Value

true - successful, otherwise - false.

CreateButton

Creates button.

```
virtual bool CreateButton()
```

Return Value

true - successful, otherwise - false.

CreateLabel

Creates label.

```
virtual bool CreateLabel()
```

Return Value

true - successful, otherwise - false.

OnClickButton

The virtual handler of the control "ClickButton" (button click) internal event.

```
virtual bool OnClickButton()
```

Return Value

true - event processed, otherwise - false.

OnClickLabel

The virtual handler of the control "ClickLabel" (click on the label) internal event.

```
virtual bool OnClickLabel ()
```

Return Value

true - event processed, otherwise - false.

CRadioGroup

CRadioGroup is a class of RadioGroup complex control (with dependent controls).

Description

CRadioGroup enables creation of a control allowing the display and editing the enumerable type field.

Declaration

```
class CRadioGroup : public CWndClient
```

Title

```
#include <Controls\RadioGroup.mqh>
```

Inheritance hierarchy

[CObject](#)

[CWnd](#)

[CWndContainer](#)

[CWndClient](#)

CRadioGroup

Result of the [code](#) provided below:

Class Methods by Groups

Create

Create	Creates control
Chart event handlers	
OnEvent	Event handler of all chart events
Add	
AddItem	Adds new item
Read-only data	
Value	Gets the value associated with the control
Dependent controls	
CreateButton	Creates new CRadioButton item at a specified index
Dependent controls event handlers	
OnVScrollShow	"Show" internal event handler (virtual) of VScroll dependent control
OnVScrollHide	"Hide" internal event handler (virtual) of VScroll dependent control
OnScrollLineDown	"ScrollLineDown" internal event handler (virtual) of VScroll dependent control
OnScrollLineUp	"ScrollLineUp" internal event handler (virtual) of VScroll dependent control
OnChangeItem	"ChangeItem" internal event handler (virtual)
Redraw	
Redraw	Redraws the group of items
RowState	Sets the state of the specified item
Select	Selects the current item

                  const string& sparam) // event parameter of the string type  
{  
    ExtDialog.ChartEvent(id,lparam,dparam,sparam);  
}
```

Create

Creates new CRadioGroup control.

```
virtual bool Create(  
    const long    chart,      // chart ID  
    const string  name,      // name  
    const int     subwin,     // chart subwindow  
    const int     x1,        // coordinate  
    const int     y1,        // coordinate  
    const int     x2,        // coordinate  
    const int     y2         // coordinate  
)
```

Parameters

chart

[in] ID of the chart, at which the control is created.

name

[in] Unique name of the control.

subwin

[in] Subwindow of the chart, at which the control is created.

x1

[in] X coordinate of the upper left corner.

y1

[in] Y coordinate of the upper left corner.

x2

[in] X coordinate of the lower right corner.

y2

[in] Y coordinate of the lower right corner.

Return Value

true - successful, otherwise - false.

OnEvent

Chart event handler.

```
virtual bool OnEvent(  
    const int      id,           // ID  
    const long&    lparam,       // parameter  
    const double&  dparam,       // parameter  
    const string&  sparam        // parameter  
)
```

Parameters

id

[in] Event ID.

lparam

[in] Event parameter of [long](#) type passed by reference.

dparam

[in] Event parameter of [double](#) type passed by reference.

sparam

[in] Event parameter of [string](#) type passed by reference.

Return Value

true - event processed, otherwise - false.

AddItem

Adds an item to the control.

```
bool AddItem(  
    const string item,      // text  
    const long  value=0    // value  
)
```

Parameters

item

[in] Added control label text.

value=0

[in] Value associated with the added control.

Return Value

true - successful, otherwise - false.

Value

Gets the value associated with the control.

```
long Value()
```

Return Value

The value associated with the control.

Note

The value depends on state of all CRadioButton items of the CRadioGroup control.

CreateButton

Creates new CRadioButton class instance at a specified index.

```
bool CreateButton(  
    const int index    // index  
)
```

Parameters

index

[in] Index of the new item in the CRadioGroup.

Return Value

true - successful, otherwise - false.

OnVScrollShow

The virtual handler of the dependent VScroll (vertical scroll) control "Show" internal event.

```
virtual bool OnVScrollShow()
```

Return Value

true - event processed, otherwise - false.

OnVScrollHide

The virtual handler of the dependent VScroll (vertical scroll) control "Hide" internal event.

```
virtual bool OnVScrollHide()
```

Return Value

true - event processed, otherwise - false.

OnScrollLineDown

The virtual handler of the dependent VScroll (vertical scroll) control "ScrollLineDown" internal event.

```
virtual bool OnScrollLineDown ()
```

Return Value

true - event processed, otherwise - false.

OnScrollLineUp

The virtual handler of the dependent VScroll (vertical scroll) control "ScrollLineUp" internal event.

```
virtual bool OnScrollLineUp()
```

Return Value

true - event processed, otherwise - false.

OnChangeItem

The virtual handler of the control "Changeltem" (item change) event.

```
virtual bool OnChangeItem(  
    const int index    // index  
)
```

Parameters

index

[in] Index of the changed item.

Return Value

true - event processed, otherwise - false.

Redraw

Redraws the control.

```
bool Redraw()
```

Return Value

true - successful, otherwise - false.

RowState

Changes the state of an item.

```
bool RowState(  
    const int    index,      // index  
    const bool   select      // state  
)
```

Parameters

index

[in] Item index to change.

select

[in] New state.

Return Value

true - successful, otherwise - false.

Select

Selects the current item.

```
void Select(  
    const int index    // index  
)
```

Parameters

index

[in] Item index to select.

Return Value

None.

CSpinEdit

CSpinEdit is a class of SpinEdit complex control (with dependent controls).

Description

CSpinEdit class is intended for creation of a control, which allows editing a value of integer type with a specified step and within specified limitations.

Declaration

```
class CSpinEdit : public CWndContainer
```

Title

```
#include <Controls\SpinEdit.mqh>
```

Inheritance hierarchy

[CWnd](#)

[CWndContainer](#)

CSpinEdit

Result of the [code](#) provided below:

Class Methods by Groups

Create

Create	Creates control
Chart event handlers	
OnEvent	Event handler of all chart events
Properties	
MinValue	Gets/sets the minimal allowed value
MaxValue	Gets/sets the maximal allowed value
State	
Value	Gets/sets the current value
Dependent controls	
CreateEdit	Creates dependent control (edit)
CreateInc	Creates dependent control (increment button)
CreateDec	Creates dependent control (decrement button)
Dependent controls event handlers	
OnClickInc	"ClickInc" internal event handler (virtual)
OnClickDec	"ClickDec" internal event handler (virtual)
Internal event handlers	
OnChangeValue	"ChangeValue" internal event handler (virtual)

}

```

Create

Creates new CSpinEdit control.

```
virtual bool Create(  
    const long    chart,      // chart ID  
    const string  name,      // name  
    const int     subwin,     // chart subwindow  
    const int     x1,        // coordinate  
    const int     y1,        // coordinate  
    const int     x2,        // coordinate  
    const int     y2         // coordinate  
)
```

Parameters

chart

[in] ID of the chart, at which the control is created.

name

[in] Unique name of the control.

subwin

[in] Subwindow of the chart, at which the control is created.

x1

[in] X coordinate of the upper left corner.

y1

[in] Y coordinate of the upper left corner.

x2

[in] X coordinate of the lower right corner.

y2

[in] Y coordinate of the lower right corner.

Return Value

true - successful, otherwise - false.

OnEvent

Chart event handler.

```
virtual bool OnEvent(  
    const int      id,           // ID  
    const long&    lparam,       // parameter  
    const double&  dparam,       // parameter  
    const string&  sparam        // parameter  
)
```

Parameters

id

[in] Event ID.

lparam

[in] Event parameter of [long](#) type passed by reference.

dparam

[in] Event parameter of [double](#) type passed by reference.

sparam

[in] Event parameter of [string](#) type passed by reference.

Return Value

true - event processed, otherwise - false.

MinValue (Get method)

Gets the value of "MinValue" property (minimal value) of the control.

```
int MinValue() const
```

Return Value

The value of "MinValue" property.

MinValue (Set method)

Sets the value of "MinValue" property (minimal value) of the control.

```
void MinValue(  
    const int value    // value  
)
```

Parameters

value

[in] New value of "MinValue" property.

Return Value

None.

MaxValue (Get method)

Gets the value of "MaxValue" property (maximal value) of the control.

```
int MaxValue() const
```

Return Value

The value of "MaxValue" property.

MaxValue (Set method)

Sets the value of "MaxValue" property (maximal value) of the control.

```
void MaxValue(  
    const int value    // value  
)
```

Parameters

value

[in] New value of "MaxValue" property.

Return Value

None.

Value (Get method)

Gets the "Value" property (current value) of the control.

```
int Value() const
```

Return Value

The "Value" property.

Value (Set method)

Sets the "Value" property (current value) of the control.

```
void Value(  
    const int value    // value  
)
```

Parameters

value

[in] New "Value" property.

Return Value

None.

CreateEdit

Creates dependent control (CEdit).

```
virtual bool CreateEdit()
```

Return Value

true - successful, otherwise - false.

CreateInc

Creates dependent control (increment button).

```
virtual bool CreateInc()
```

Return Value

true - successful, otherwise - false.

CreateDec

Creates dependent control (decrement button).

```
virtual bool CreateDec()
```

Return Value

true - successful, otherwise - false.

OnClickInc

The virtual handler of the control "ClickInc" (mouse click on the increment button) internal event.

```
virtual bool OnClickInc()
```

Return Value

true - event processed, otherwise - false.

OnClickDec

The virtual handler of the control "ClickDec" (mouse click on the decrement button) internal event.

```
virtual bool OnClickDec()
```

Return Value

true - event processed, otherwise - false.

OnChangeValue

The virtual handler of the control "ChangeValue" (changing the current value) internal event.

```
virtual bool OnChangeValue()
```

Return Value

true - event processed, otherwise - false.

CDialog

CDialog is class of the Dialog complex control.

Description

CDialog class is intended to combine the controls with different functions in the group.

Declaration

```
class CDialog : public CWndContainer
```

Title

```
#include <Controls\Dialog.mqh>
```

Create

Creates new CDialog control.

```
virtual bool Create(  
    const long    chart,      // chart ID  
    const string  name,      // name  
    const int     subwin,    // chart subwindow  
    const int     x1,        // coordinate  
    const int     y1,        // coordinate  
    const int     x2,        // coordinate  
    const int     y2        // coordinate  
)
```

Parameters

chart

[in] ID of the chart, at which the control is created.

name

[in] Unique name of the control.

subwin

[in] Subwindow of the chart, at which the control is created.

x1

[in] X coordinate of the upper left corner.

y1

[in] Y coordinate of the upper left corner.

x2

[in] X coordinate of the lower right corner.

y2

[in] Y coordinate of the lower right corner.

Return Value

true - successful, otherwise - false.

OnEvent

Chart event handler.

```
virtual bool OnEvent(  
    const int      id,           // ID  
    const long&    lparam,       // parameter  
    const double&  dparam,       // parameter  
    const string&  sparam        // parameter  
)
```

Parameters

id

[in] Event ID.

lparam

[in] Event parameter of [long](#) type passed by reference.

dparam

[in] Event parameter of [double](#) type passed by reference.

sparam

[in] Event parameter of [string](#) type passed by reference.

Return Value

true - event processed, otherwise - false.

Caption (Get method)

Gets the "Caption" property of the CDialog control.

```
string MinValue() const
```

Return Value

The "Caption" property.

Caption (Set method)

Sets the "Caption" property of the CDialog control.

```
bool Caption(  
    const string text    // text  
)
```

Parameters

text

[in] New value of "Caption" property.

Return Value

true - successful, otherwise - false.

Add

Adds control to the client area by pointer.

```
bool Add(  
    CWnd *control,           // pointer  
)
```

Parameters

control

[in] Pointer to control.

Return Value

true - successful, otherwise - false.

Add

Adds control to the client area by reference.

```
bool Add(  
    CWnd &control,           // reference  
)
```

Parameters

control

[in] Reference to control.

Return Value

true - successful, otherwise - false.

CreateWhiteBorder

Creates dependent control (white border).

```
virtual bool CreateWhiteBorder()
```

Return Value

true - successful, otherwise - false.

CreateBackground

Creates dependent control (background).

```
virtual bool CreateBackground()
```

Return Value

true - successful, otherwise - false.

CreateCaption

Creates dependent control (caption).

```
virtual bool CreateCaption()
```

Return Value

true - successful, otherwise - false.

CreateButtonClose

Creates dependent control (close button)

```
virtual bool CreateButtonClose()
```

Return Value

true - successful, otherwise - false.

CreateClientArea

Creates dependent control (client area).

```
virtual bool CreateClientArea ()
```

Return Value

true - successful, otherwise - false.

OnClickCaption

The virtual handler of the control "ClickCaption" internal event.

```
virtual bool OnClickCaption()
```

Return Value

true - successful, otherwise - false.

OnClickButtonClose

The virtual handler of the control "ClickButtonClose" internal event.

```
virtual bool OnClickButtonClose()
```

Return Value

true - successful, otherwise - false.

ClientAreaVisible

Sets a flag indicating whether the client area is visible.

```
bool ClientAreaVisible(  
    const bool visible    // visibility flag  
)
```

Parameters

visible

[in] Visibility flag.

Return Value

true - successful, otherwise - false.

ClientAreaLeft

Gets X coordinate of the upper-left corner of the control client area.

```
int ClientAreaLeft()
```

Return Value

The X coordinate of the upper-left corner of the control client area.

ClientAreaTop

Gets Y coordinate of the upper-left corner of the control client area.

```
int ClientAreaTop()
```

Return Value

The Y coordinate of the upper-left corner of the control client area.

ClientAreaRight

Gets X coordinate of the lower-right corner of the control client area.

```
int ClientAreaTop()
```

Return Value

The X coordinate of the lower-right corner of the control client area.

ClientAreaBottom

Gets Y coordinate of the lower-right corner of the control client area.

```
int ClientAreaBottom()
```

Return Value

The Y coordinate of the lower-right corner of the control client area.

ClientAreaWidth

Gets the width of the control client area.

```
int ClientAreaWidth()
```

Return Value

The width of the client area.

ClientAreaHeight

Gets the height of the control client area.

```
int ClientAreaHeight ()
```

Return Value

The height of the control client area.

OnDialogDragStart

The virtual handler of the control "DialogDragStart" event.

```
virtual bool OnDialogDragStart ()
```

Return Value

true - event processed, otherwise - false.

Note

The "DialogDragStart" event occurs at start of the drag of the control.

OnDialogDragProcess

The virtual handler of the control "DialogDragProcess" event.

```
virtual bool OnDialogDragProcess()
```

Return Value

true - event processed, otherwise - false.

Note

The "DialogDragProcess" event occurs when the control is dragged.

OnDialogDragEnd

The virtual handler of the control "DialogDragEnd" event.

```
virtual bool OnDialogDragEnd()
```

Return Value

true - event processed, otherwise - false.

Note

The "DialogDragEnd" event occurs at the end of the drag of the control.

CAppDialog

CAppDialog is a class of Application Dialog complex control (with dependent controls).

Description

CAppDialog class is intended to combine the controls with different functions in the group inside the MQL5 program.

Declaration

```
class CAppDialog : public CDialog
```

Title

```
#include <Controls\Dialog.mqh>
```

Inheritance hierarchy

Chart events processing	
ChartEvent	Event handler of all chart events
Settings	
Minimized	Sets a value indicating whether the control is minimized
Save/Load	
IniFileSave	Saves the control state to file
IniFileLoad	Loads the control state from file

IniFileName	Sets the file name for loading/saving the control state
IniFileExt	Sets the file extension for loading/saving the control state
Initialization	
CreateCommon	Common initialization method
CreateExpert	Initialization method for working in Expert Advisors
CreateIndicator	Initialization method for working in indicators
Dependent controls	
CreateButtonMinMax	Creates dependent controls (minimize/maximize buttons)
Dependent controls event handlers	
OnClickButtonClose	"ClickButtonClose" internal event handler (virtual)
OnClickButtonMinMax	"ClickButtonMinMax" internal event handler (virtual)
External events	
OnAnotherApplicationClose	Event handler of external events (virtual)
Methods	
Rebound	Sets new coordinates of the control using CRect class coordinates
Minimize	Shows the control in the minimized state
Maximize	Shows the control in the maximized (restored) state
CreateInstanceld	Creates a unique Id for the names of the control objects
ProgramName	Gets the name of MQL5 program, at which the control is used
SubwinOff	Get the Y offset of the control subwindow

Methods inherited from class CDialog

[Caption](#), [Caption](#), [Add](#), [Add](#)

Create

Creates new CAppDialog control.

```
virtual bool Create(  
    const long    chart,      // chart ID  
    const string  name,      // name  
    const int     subwin,    // chart subwindow  
    const int     x1,        // coordinate  
    const int     y1,        // coordinate  
    const int     x2,        // coordinate  
    const int     y2        // coordinate  
)
```

Parameters

chart

[in] ID of the chart, at which the ontrol is created.

name

[in] Unique name of the control.

subwin

[in] Subwindow of the chart, at which the ontrol is created.

x1

[in] X coordinate of the upper left corner.

y1

[in] Y coordinate of the upper left corner.

x2

[in] X coordinate of the lower right corner.

y2

[in] Y coordinate of the lower right corner.

Return Value

true - successful, otherwise - false.

Destroy

Destroys control.

```
virtual bool Destroy()
```

Return Value

true - successful, otherwise - false.

OnEvent

Chart event handler.

```
virtual bool OnEvent(  
    const int      id,           // ID  
    const long&    lparam,      // parameter  
    const double&  dparam,      // parameter  
    const string&  sparam       // parameter  
)
```

Parameters

id

[in] Event ID.

lparam

[in] Event parameter of [long](#) type passed by reference.

dparam

[in] Event parameter of [double](#) type passed by reference.

sparam

[in] Event parameter of [string](#) type passed by reference.

Return Value

true - event processed, otherwise - false.

Run

Runs control.

```
bool Run()
```

Return Value

true - successful, otherwise - false.

ChartEvent

Virtual handler of the control events.

```
virtual bool ChartEvent(  
    const int      id,           // ID  
    const long&    lparam,       // parameter  
    const double&  dparam,       // parameter  
    const string&  sparam        // parameter  
)
```

Parameters

id

[in] Event ID.

lparam

[in] Event parameter of [long](#) type passed by reference.

dparam

[in] Event parameter of [double](#) type passed by reference.

sparam

[in] Event parameter of [string](#) type passed by reference.

Return Value

true - event processed, otherwise - false.

Minimized

Sets the value of "Minimized" (window state) property of the control.

```
bool Minimized(  
    const bool flag    // state  
)
```

Parameters

flag

[in] New state.

Return Value

true - successful, otherwise - false.

IniFileSave

Saves the control state to file.

```
void IniFileSave()
```

Return Value

true - successful, otherwise - false.

IniFileLoad

Loads the control state from file.

```
void IniFileLoad()
```

Return Value

true - successful, otherwise - false.

IniFileName

Sets the file name for loading/saving the control state.

```
virtual string IniFileName() const
```

Return Value

File name for loading/saving of the control state.

Note

The file name includes the name of the Expert Advisor/indicator and working symbol, on which MQL5 program is launched.

IniFileExt

Sets the file extension for loading/saving the control state.

```
virtual string IniFileExt() const
```

Return Value

File extension used for loading/saving of the control state.

CreateCommon

Common initialization method.

```
bool CreateCommon(  
    const long    chart,        // chart ID  
    const string  name,         // name  
    const int     subwin,       // chart subwindow  
)
```

Parameters

chart

[in] ID of the chart, at which the control is created.

name

[in] Unique name of the control.

subwin

[in] Subwindow of the chart, at which the control is created.

Return Value

true - successful, otherwise - false.

CreateExpert

Initialization method for working in Expert Advisors.

```
bool CreateExpert (
    const int    x1,          // coordinate
    const int    y1,          // coordinate
    const int    x2,          // coordinate
    const int    y2          // coordinate
)
```

Parameters

x1

[in] X coordinate of the upper left corner.

y1

[in] Y coordinate of the upper left corner.

x2

[in] X coordinate of the lower right corner.

y2

[in] Y coordinate of the lower right corner.

Return Value

true - successful, otherwise - false.

CreateIndicator

Initialization method for working in indicators.

```
bool CreateIndicator(  
    const int    x1,          // coordinate  
    const int    y1,          // coordinate  
    const int    x2,          // coordinate  
    const int    y2           // coordinate  
)
```

Parameters

x1

[in] X coordinate of the upper left corner.

y1

[in] Y coordinate of the upper left corner.

x2

[in] X coordinate of the lower right corner.

y2

[in] Y coordinate of the lower right corner.

Return Value

true - successful, otherwise - false.

CreateButtonMinMax

Creates dependent controls (minimize/maximize buttons).

```
virtual void CreateButtonMinMax()
```

Return Value

None.

OnClickButtonClose

The virtual handler of the control "ClickButtonClose" (mouse click on close button) internal event.

```
virtual void OnClickButtonClose()
```

Return Value

None.

OnClickButtonMinMax

The virtual handler of the control "ClickButtonMinMax" (mouse click on minimize/maximize button) internal event.

```
virtual void OnClickButtonClose()
```

Return Value

None.

OnAnotherApplicationClose

The virtual handler of the control external events.

```
virtual void OnAnotherApplicationClose()
```

Return Value

None.

Rebound

Sets new coordinates of the control using CRect class coordinates.

```
bool Rebound(  
    const & CRect rect    // CRect class  
)
```

Return Value

true - successful, otherwise - false.

Minimize

Shows the control window in the minimized state.

```
virtual void Minimize()
```

Return Value

true - successful, otherwise - false.

Maximize

Shows the control window in the maximized (restored) state.

```
virtual void Maximize()
```

Return Value

true - successful, otherwise - false.

CreateInstanceId

Creates a unique prefix for the names of the control objects.

```
string CreateInstanceId()
```

Return Value

Prefix for the object names.

ProgramName

Gets the name of the MQL5 program, at which the control is used.

```
string ProgramName ()
```

Return Value

Name of the MQL5 program.

SubwinOff

Gets the Y offset of the control subwindow.

```
void SubwinOff()
```

Return Value

None.

Moving from MQL4 to MQL5

MQL5 is the evolution of its predecessor - the MQL4 programming language, in which numerous indicators, scripts, and Expert Advisors were written. Despite the fact that the new programming language is maximally compatible with the previous-generation language, there are still some differences between these languages. And when transferring programs these differences should be noted.

This section contains information intended to facilitate the adaptation of codes to the new MQL5 language for programmers who know MQL4.

First it should be noted:

- The new language does not contain functions `start()`, `init()` and `deinit()`.
- No limit for the number of indicator buffers.
- DLLs are loaded immediately after loading an Expert Advisor (or any other mql5 program).
- Check of logical conditions is shortened.
- When limits of an array are exceeded, the current performance is terminated (critically - with the output of an errors).
- Precedence of operators like in C + +.
- The language offers the implicit type cast (even from string to a number).
- Local variables are not initialized automatically (except for strings).
- Common local arrays are automatically deleted.

Special Functions `init`, `start` and `deinit`

The MQL4 language contained only three predefined functions that could be used in the indicator, script or Expert Advisor (not taking into account the include files `*.mqh` and library files). In MQL5 there are no such functions, but there are their analogues. The table shows the approximate correspondence of functions.

MQL4	MQL5
<code>init</code>	<code>OnInit</code>
<code>start</code>	<code>OnStart</code>
<code>deinit</code>	<code>OnDeinit</code>

Functions [OnInit](#) and [OnDeinit](#) perform the same role as `init` and `deinit` in MQL4 - they are designed to locate the code, which must be performed during initialization and deinitialization of mql5 programs. You can either just rename these functions accordingly, or leave them as they are, but add calls of these functions in corresponding places.

Example:

```
void OnInit()  
{  
    //--- Call function upon initialization  
    init();  
}
```

```
    }
    void OnDeinit(const int reason)
    {
        //--- Call function upon deinitialization
        deinit();
        //---
    }
```

The start function is replaced by [OnStart](#) only in scripts. In Expert Advisors and indicators it should be renamed to [OnTick](#) and [OnCalculate](#), respectively. The code that is to be executed during a mql5 program operation should be located in these three functions:

mql5-program	main function
script	OnStart
indicator	OnCalculate
Expert Advisor	OnTick

If the indicator or script code does not contain the main function, or the function name differs from the required one, the call of this function is not performed. It means, if the source code of a script doesn't contain OnStart, such a code will be compiled as an Expert Advisor.

If an indicator code doesn't contain the OnCalculate function, the compilation of such an indicator is impossible.

Predefined Variables

In MQL5 there are no such predefined variables as Ask, Bid, Bars. Variables Point and Digits have a slightly different spelling:

MQL4	MQL5
Digits	_Digits
Point	_Point
	_LastError
	_Period
	_Symbol
	_StopFlag
	_UninitReason

Access to Timeseries

In MQL5 there are no such predefined timeseries as Open[], High[], Low[], Close[], Volume[] and Time[]. The necessary depth of a timeseries can now be set using corresponding [functions to access timeseries](#).

Expert Advisors

Expert Advisors in MQL5 do not require the obligatory presence of functions that handle the [events](#) of a new tick receipt - OnTick, as it was in MQL4 (the start function in MQL4 is executed when a new tick is received). In MQL5 Expert Advisors can contain pre-defined handler functions of several types of events:

- [OnTick](#) - receipt of a new tick;
- [OnTimer](#) - timer event;
- [OnTrade](#) - trade event;
- [OnChartEvent](#) - events of input from the keyboard and mouse, events of a graphic object moving, event of a text editing completion in the entry field of the LabelEdit object;
- [OnBookEvent](#) - event of Depth of Market status change.

Custom Indicators

In MQL4, the number of indicator buffers is limited and can't exceed 8. In MQL5 there are no such limitations, but it should be remembered that each indicator buffer requires allocation of a certain part of memory for its location in the terminal, so the new possibility should not be abused.

MQL4 offered only 6 types of custom indicator plotting; while MQL5 now offers 18 [drawing styles](#). The names of drawing types haven't changed, but the ideology of the graphical representation of indicators has changed significantly.

The direction of indexing in indicator buffers also differs. By default, in MQL5 all the indicator buffers have the behavior of common arrays, i.e. 0 indexed element is the oldest one in the history, and as the index increases, we move from the oldest data to the most recent ones.

The only function for working with [custom indicators](#) that was preserved from MQL4 is [SetIndexBuffer](#). But its call has changed; now you should specify [type of data to be stored in an array](#), linked to the indicator buffer.

Properties of custom indicators also have changed and expanded. New functions for [accessing timeseries](#) have been added, so the total calculation algorithm must be reconsidered.

Graphical Objects

The number of graphical objects in MQL5 has been significantly increased. Besides, graphical objects can now be positioned in time with the accuracy of a second in a chart of any timeframe - now object anchor points are not rounded off to the bar opening time in the current price chart.

For the Arrow, Text and Label objects now you can specify [binding methods](#), and for the Label, Button, Chart, Bitmap Label and Edit objects you can set [chart corner to which an object is attached](#).

List of MQL5 Functions

All MQL5 functions in alphabetical order.

Function	Action	Section
<u>AccountInfoDouble</u>	Returns a value of double type of the corresponding account property	<u>Account Information</u>
<u>AccountInfoInteger</u>	Returns a value of integer type (bool, int or long) of the corresponding account property	<u>Account Information</u>
<u>AccountInfoString</u>	Returns a value string type corresponding account property	<u>Account Information</u>
<u>acos</u>	Returns the arc cosine of x in radians	<u>Math Functions</u>
<u>Alert</u>	Displays a message in a separate window	<u>Common Functions</u>
<u>ArrayBsearch</u>	Searches for a specified value in a multidimensional numeric array sorted ascending	<u>Array Functions</u>
<u>ArrayCompare</u>	Returns the result of comparing two arrays of <u>simple types</u> or custom structures without <u>complex objects</u>	<u>Array Functions</u>
<u>ArrayCopy</u>	Copies one array into another	<u>Array Functions</u>
<u>ArrayFill</u>	Fills an array with the specified value	<u>Array Functions</u>
<u>ArrayFree</u>	Frees up buffer of any dynamic array and sets the size of the zero dimension in 0.	<u>Array Functions</u>
<u>ArrayGetAsSeries</u>	Checks direction of array indexing	<u>Array Functions</u>
<u>ArrayInitialize</u>	Sets all elements of a numeric array into a single value	<u>Array Functions</u>
<u>ArrayIsDynamic</u>	Checks whether an array is dynamic	<u>Array Functions</u>
<u>ArrayIsSeries</u>	Checks whether an array is a timeseries	<u>Array Functions</u>

<u>ArrayMaximum</u>	Searches for the largest element in the first dimension of a multidimensional numeric array	<u>Array Functions</u>
<u>ArrayMinimum</u>	Searches for the lowest element in the first dimension of a multidimensional numeric array	<u>Array Functions</u>
<u>ArrayRange</u>	Returns the number of elements in the specified dimension of the array	<u>Array Functions</u>
<u>ArrayResize</u>	Sets the new size in the first dimension of the array	<u>Array Functions</u>
<u>ArraySetAsSeries</u>	Sets the direction of array indexing	<u>Array Functions</u>
<u>ArraySize</u>	Returns the number of elements in the array	<u>Array Functions</u>
<u>ArraySort</u>	Sorting of numeric arrays by the first dimension	<u>Array Functions</u>
<u>asin</u>	Returns the arc sine of x in radians	<u>Math Functions</u>
<u>atan</u>	Returns the arc tangent of x in radians	<u>Math Functions</u>
<u>Bars</u>	Returns the number of bars the history for a specified symbol and period	<u>Timeseries and Indicators Access</u>
<u>BarsCalculated</u>	Returns the number of calculated data in an indicator buffer or -1 in the case of error (data hasn't been calculated yet)	<u>Timeseries and Indicators Access</u>
<u>ceil</u>	Returns integer numeric value closest from above	<u>Math Functions</u>
<u>CharArrayToString</u>	Converting symbol code (ansi) into one-symbol array	<u>Conversion Functions</u>
<u>ChartApplyTemplate</u>	Applies a specific template from a specified file to the chart	<u>Chart Operations</u>
<u>ChartClose</u>	Closes the specified chart	<u>Chart Operations</u>
<u>ChartFirst</u>	Returns the ID of the first chart of the client terminal	<u>Chart Operations</u>

<u>ChartGetDouble</u>	Returns the double value property of the specified chart	<u>Chart Operations</u>
<u>ChartGetInteger</u>	Returns the integer value property of the specified chart	<u>Chart Operations</u>
<u>ChartGetString</u>	Returns the string value property of the specified chart	<u>Chart Operations</u>
<u>ChartID</u>	Returns the ID of the current chart	<u>Chart Operations</u>
<u>ChartIndicatorAdd</u>	Adds an indicator with the specified handle into a specified chart window	<u>Chart Operations</u>
<u>ChartIndicatorDelete</u>	Removes an indicator with a specified name from the specified chart window	<u>Chart Operations</u>
<u>ChartIndicatorGet</u>	Returns the handle of the indicator with the specified short name in the specified chart window	<u>Chart Operations</u>
<u>ChartIndicatorName</u>	Returns the short name of the indicator by the number in the indicators list on the specified chart window	<u>Chart Operations</u>
<u>ChartIndicatorsTotal</u>	Returns the number of all indicators applied to the specified chart window.	<u>Chart Operations</u>
<u>ChartNavigate</u>	Performs shift of the specified chart by the specified number of bars relative to the specified position in the chart	<u>Chart Operations</u>
<u>ChartNext</u>	Returns the chart ID of the chart next to the specified one	<u>Chart Operations</u>
<u>ChartOpen</u>	Opens a new chart with the specified symbol and period	<u>Chart Operations</u>
<u>CharToString</u>	Converting a symbol code into a one-character string	<u>Conversion Functions</u>
<u>ChartPeriod</u>	Returns the period value of the specified chart	<u>Chart Operations</u>
<u>ChartPriceOnDropped</u>	Returns the price coordinate of the chart point, the Expert Advisor or script has been dropped to	<u>Chart Operations</u>

<u>ChartRedraw</u>	Calls a forced redrawing of a specified chart	<u>Chart Operations</u>
<u>ChartSaveTemplate</u>	Saves current chart settings in a template with a specified name	<u>Chart Operations</u>
<u>ChartScreenShot</u>	Provides a screenshot of the chart of its current state in a GIF, PNG or BMP format depending on specified extension	<u>Chart Operations</u>
<u>ChartSetDouble</u>	Sets the double value for a corresponding property of the specified chart	<u>Chart Operations</u>
<u>ChartSetInteger</u>	Sets the integer value (datetime, int, color, bool or char) for a corresponding property of the specified chart	<u>Chart Operations</u>
<u>ChartSetString</u>	Sets the string value for a corresponding property of the specified chart	<u>Chart Operations</u>
<u>ChartSetSymbolPeriod</u>	Changes the symbol value and a period of the specified chart	<u>Chart Operations</u>
<u>ChartSymbol</u>	Returns the symbol name of the specified chart	<u>Chart Operations</u>
<u>ChartTimeOnDropped</u>	Returns the time coordinate of the chart point, the Expert Advisor or script has been dropped to	<u>Chart Operations</u>
<u>ChartTimePriceToXY</u>	Converts the coordinates of a chart from the time/price representation to the X and Y coordinates	<u>Chart Operations</u>
<u>ChartWindowFind</u>	Returns the number of a subwindow where an indicator is drawn	<u>Chart Operations</u>
<u>ChartWindowOnDropped</u>	Returns the number (index) of the chart subwindow, the Expert Advisor or script has been dropped to	<u>Chart Operations</u>
<u>ChartXOnDropped</u>	Returns the X coordinate of the chart point, the Expert Advisor or script has been dropped to	<u>Chart Operations</u>

<u>ChartXYToTimePrice</u>	Converts the X and Y coordinates on a chart to the time and price values	<u>Chart Operations</u>
<u>ChartYOnDropped</u>	Returns the Y coordinate of the chart point, the Expert Advisor or script has been dropped to	<u>Chart Operations</u>
<u>CheckPointer</u>	Returns the type of the object pointer	<u>Common Functions</u>
<u>CLBufferCreate</u>	Creates an OpenCL buffer	<u>Working with OpenCL</u>
<u>CLBufferFree</u>	Deletes an OpenCL buffer	<u>Working with OpenCL</u>
<u>CLBufferRead</u>	Reads an OpenCL buffer into an array	<u>Working with OpenCL</u>
<u>CLBufferWrite</u>	Writes an array into an OpenCL buffer	<u>Working with OpenCL</u>
<u>CLContextCreate</u>	Creates an OpenCL context	<u>Working with OpenCL</u>
<u>CLContextFree</u>	Removes an OpenCL context	<u>Working with OpenCL</u>
<u>CLExecute</u>	Runs an OpenCL program	<u>Working with OpenCL</u>
<u>CLGetDeviceInfo</u>	Receives device property from OpenCL driver	<u>Working with OpenCL</u>
<u>CLGetInfoInteger</u>	Returns the value of an integer property for an OpenCL object or device	<u>Working with OpenCL</u>
<u>CLHandleType</u>	Returns the type of an OpenCL handle as a value of the ENUM_OPENCL_HANDLE_TYPE enumeration	<u>Working with OpenCL</u>
<u>CLKernelCreate</u>	Creates an OpenCL start function	<u>Working with OpenCL</u>
<u>CLKernelFree</u>	Removes an OpenCL start function	<u>Working with OpenCL</u>
<u>CLProgramCreate</u>	Creates an OpenCL program from a source code	<u>Working with OpenCL</u>
<u>CLProgramFree</u>	Removes an OpenCL program	<u>Working with OpenCL</u>
<u>CLSetKernelArg</u>	Sets a parameter for the OpenCL function	<u>Working with OpenCL</u>
<u>CLSetKernelArgMem</u>	Sets an OpenCL buffer as a parameter of the OpenCL function	<u>Working with OpenCL</u>

<u>ColorToARGB</u>	Converting color type to uint type to receive ARGB representation of the color.	<u>Conversion Functions</u>
<u>ColorToString</u>	Converting color value into string as "R,G,B"	<u>Conversion Functions</u>
<u>Comment</u>	Outputs a comment in the left top corner of the chart	<u>Common Functions</u>
<u>CopyBuffer</u>	Gets data of a specified buffer from a specified indicator into an array	<u>Timeseries and Indicators Access</u>
<u>CopyClose</u>	Gets history data on bar closing price for a specified symbol and period into an array	<u>Timeseries and Indicators Access</u>
<u>CopyHigh</u>	Gets history data on maximal bar price for a specified symbol and period into an array	<u>Timeseries and Indicators Access</u>
<u>CopyLow</u>	Gets history data on minimal bar price for a specified symbol and period into an array	<u>Timeseries and Indicators Access</u>
<u>CopyOpen</u>	Gets history data on bar opening price for a specified symbol and period into an array	<u>Timeseries and Indicators Access</u>
<u>CopyRates</u>	Gets history data of the <u>Rates</u> structure for a specified symbol and period into an array	<u>Timeseries and Indicators Access</u>
<u>CopyRealVolume</u>	Gets history data on trade volumes for a specified symbol and period into an array	<u>Timeseries and Indicators Access</u>
<u>CopySpread</u>	Gets history data on spreads for a specified symbol and period into an array	<u>Timeseries and Indicators Access</u>
<u>CopyTicks</u>	Gets ticks accumulated by the terminal for the current working session into an array	<u>Timeseries and Indicators Access</u>
<u>CopyTickVolume</u>	Gets history data on tick volumes for a specified symbol and period into an array	<u>Timeseries and Indicators Access</u>

<u>CopyTime</u>	Gets history data on bar opening time for a specified symbol and period into an array	<u>Timeseries and Indicators Access</u>
<u>cos</u>	Returns the cosine of a number	<u>Math Functions</u>
<u>CryptDecode</u>	Performs the inverse transformation of the data from array	<u>Common Functions</u>
<u>CryptEncode</u>	Transforms the data from array with the specified method	<u>Common Functions</u>
<u>DebugBreak</u>	Program breakpoint in debugging	<u>Common Functions</u>
<u>Digits</u>	Returns the number of decimal digits determining the accuracy of the price value of the current chart symbol	<u>Checkup</u>
<u>DoubleToString</u>	Converting a numeric value to a text line with a specified accuracy	<u>Conversion Functions</u>
<u>EnumToString</u>	Converting an enumeration value of any type to string	<u>Conversion Functions</u>
<u>EventChartCustom</u>	Generates a custom event for the specified chart	<u>Working with Events</u>
<u>EventKillTimer</u>	Stops the generation of events by the timer in the current chart	<u>Working with Events</u>
<u>EventSetMillisecondTimer</u>	Launches event generator of the high-resolution timer with a period less than 1 second for the current chart	<u>Working with Events</u>
<u>EventSetTimer</u>	Starts the timer event generator with the specified periodicity for the current chart	<u>Working with Events</u>
<u>exp</u>	Returns exponent of a number	<u>Math Functions</u>
<u>ExpertRemove</u>	Stops Expert Advisor and unloads it from the chart	<u>Common Functions</u>
<u>fabs</u>	Returns absolute value (modulus) of the specified numeric value	<u>Math Functions</u>

<u>FileClose</u>	Closes a previously opened file	<u>File Functions</u>
<u>FileCopy</u>	Copies the original file from a local or shared folder to another file	<u>File Functions</u>
<u>FileDelete</u>	Deletes a specified file	<u>File Functions</u>
<u>FileFindClose</u>	Closes search handle	<u>File Functions</u>
<u>FileFindFirst</u>	Starts the search of files in a directory in accordance with the specified filter	<u>File Functions</u>
<u>FileFindNext</u>	Continues the search started by the FileFindFirst() function	<u>File Functions</u>
<u>FileFlush</u>	Writes to a disk all data remaining in the input/output file buffer	<u>File Functions</u>
<u>FileGetInteger</u>	Gets an integer property of a file	<u>File Functions</u>
<u>FilesEnding</u>	Defines the end of a file in the process of reading	<u>File Functions</u>
<u>FilesExist</u>	Checks the existence of a file	<u>File Functions</u>
<u>FilesLineEnding</u>	Defines the end of a line in a text file in the process of reading	<u>File Functions</u>
<u>FileMove</u>	Moves or renames a file	<u>File Functions</u>
<u>FileOpen</u>	Opens a file with a specified name and flag	<u>File Functions</u>
<u>FileReadArray</u>	Reads arrays of any type except for string from the file of the BIN type	<u>File Functions</u>
<u>FileReadBool</u>	Reads from the file of the CSV type a string from the current position till a delimiter (or till the end of a text line) and converts the read string to a value of bool type	<u>File Functions</u>
<u>FileReadDatetime</u>	Reads from the file of the CSV type a string of one of the formats: "YYYY.MM.DD HH:MM:SS", "YYYY.MM.DD" or "HH:MM:SS" - and converts it into a datetime value	<u>File Functions</u>

<u>FileReadDouble</u>	Reads a double value from the current position of the file pointer	<u>File Functions</u>
<u>FileReadFloat</u>	Reads a float value from the current position of the file pointer	<u>File Functions</u>
<u>FileReadInteger</u>	Reads int, short or char value from the current position of the file pointer	<u>File Functions</u>
<u>FileReadLong</u>	Reads a long type value from the current position of the file pointer	<u>File Functions</u>
<u>FileReadNumber</u>	Reads from the file of the CSV type a string from the current position till a delimiter (or till the end of a text line) and converts the read string into double value	<u>File Functions</u>
<u>FileReadString</u>	Reads a string from the current position of a file pointer from a file	<u>File Functions</u>
<u>FileReadStruct</u>	Reads the contents from a binary file into a structure passed as a parameter, from the current position of the file pointer	<u>File Functions</u>
<u>FileSeek</u>	Moves the position of the file pointer by a specified number of bytes relative to the specified position	<u>File Functions</u>
<u>FileSize</u>	Returns the size of a corresponding open file	<u>File Functions</u>
<u>FileTell</u>	Returns the current position of the file pointer of a corresponding open file	<u>File Functions</u>
<u>FileWrite</u>	Writes data to a file of CSV or TXT type	<u>File Functions</u>
<u>FileWriteArray</u>	Writes arrays of any type except for string into a file of BIN type	<u>File Functions</u>
<u>FileWriteDouble</u>	Writes value of the double type from the current position	<u>File Functions</u>

	of a file pointer into a binary file	
FileWriteFloat	Writes value of the float type from the current position of a file pointer into a binary file	File Functions
FileWriteInteger	Writes value of the int type from the current position of a file pointer into a binary file	File Functions
FileWriteLong	Writes value of the long type from the current position of a file pointer into a binary file	File Functions
FileWriteString	Writes the value of a string parameter into a BIN or TXT file starting from the current position of the file pointer	File Functions
FileWriteStruct	Writes the contents of a structure passed as a parameter into a binary file, starting from the current position of the file pointer	File Functions
floor	Returns integer numeric value closest from below	Math Functions
fmax	Returns the maximal value of the two numeric values	Math Functions
fmin	Returns the minimal value of the two numeric values	Math Functions
fmod	Returns the real remainder after the division of two numbers	Math Functions
FolderClean	Deletes all files in the specified folder	File Functions
FolderCreate	Creates a folder in the Files directory	File Functions
FolderDelete	Removes a selected directory. If the folder is not empty, then it can't be removed	File Functions
FrameAdd	Adds a frame with data	Working with Optimization Results
FrameFilter	Sets the frame reading filter and moves the pointer to the beginning	Working with Optimization Results

<u>FrameFirst</u>	Moves a pointer of frame reading to the beginning and resets the previously set filter	<u>Working with Optimization Results</u>
<u>FrameInputs</u>	Receives <u>input parameters</u> , on which the frame is formed	<u>Working with Optimization Results</u>
<u>FrameNext</u>	Reads a frame and moves the pointer to the next one	<u>Working with Optimization Results</u>
<u>GetLastError</u>	Returns the last error	<u>Checkup</u>
<u>GetPointer</u>	Returns the object <u>pointer</u>	<u>Common Functions</u>
<u>GetTickCount</u>	Returns the number of milliseconds that have elapsed since the system was started	<u>Common Functions</u>
<u>GlobalVariableCheck</u>	Checks the existence of a global variable with the specified name	<u>Global Variables of the Terminal</u>
<u>GlobalVariableDel</u>	Deletes a global variable	<u>Global Variables of the Terminal</u>
<u>GlobalVariableGet</u>	Returns the value of a global variable	<u>Global Variables of the Terminal</u>
<u>GlobalVariableName</u>	Returns the name of a global variable by its ordinal number in the list of global variables	<u>Global Variables of the Terminal</u>
<u>GlobalVariablesDeleteAll</u>	Deletes global variables with the specified prefix in their names	<u>Global Variables of the Terminal</u>
<u>GlobalVariableSet</u>	Sets the new value to a global variable	<u>Global Variables of the Terminal</u>
<u>GlobalVariableSetOnCondition</u>	Sets the new value of the existing global variable by condition	<u>Global Variables of the Terminal</u>
<u>GlobalVariablesFlush</u>	Forcibly saves contents of all global variables to a disk	<u>Global Variables of the Terminal</u>
<u>GlobalVariablesTotal</u>	Returns the total number of global variables	<u>Global Variables of the Terminal</u>
<u>GlobalVariableTemp</u>	Sets the new value to a global variable, that exists only in the current session of the terminal	<u>Global Variables of the Terminal</u>
<u>GlobalVariableTime</u>	Returns time of the last accessing the global variable	<u>Global Variables of the Terminal</u>

<u>HistoryDealGetDouble</u>	Returns the requested property of a deal in the history (double)	<u>Trade Functions</u>
<u>HistoryDealGetInteger</u>	Returns the requested property of a deal in the history (datetime or int)	<u>Trade Functions</u>
<u>HistoryDealGetString</u>	Returns the requested property of a deal in the history (string)	<u>Trade Functions</u>
<u>HistoryDealGetTicket</u>	Returns a ticket of a corresponding deal in the history	<u>Trade Functions</u>
<u>HistoryDealSelect</u>	Selects a deal in the history for further calling it through appropriate functions	<u>Trade Functions</u>
<u>HistoryDealsTotal</u>	Returns the number of deals in the history	<u>Trade Functions</u>
<u>HistoryOrderGetDouble</u>	Returns the requested property of an order in the history (double)	<u>Trade Functions</u>
<u>HistoryOrderGetInteger</u>	Returns the requested property of an order in the history (datetime or int)	<u>Trade Functions</u>
<u>HistoryOrderGetString</u>	Returns the requested property of an order in the history (string)	<u>Trade Functions</u>
<u>HistoryOrderGetTicket</u>	Return order ticket of a corresponding order in the history	<u>Trade Functions</u>
<u>HistoryOrderSelect</u>	Selects an order in the history for further working with it	<u>Trade Functions</u>
<u>HistoryOrdersTotal</u>	Returns the number of orders in the history	<u>Trade Functions</u>
<u>HistorySelect</u>	Retrieves the history of transactions and orders for the specified period of the server time	<u>Trade Functions</u>
<u>HistorySelectByPosition</u>	Requests the history of deals with a specified <u>position identifier</u> .	<u>Trade Functions</u>
<u>iAC</u>	Accelerator Oscillator	<u>Technical Indicators</u>

<u>iAD</u>	Accumulation/Distribution	<u>Technical Indicators</u>
<u>iADX</u>	Average Directional Index	<u>Technical Indicators</u>
<u>iADXWilder</u>	Average Directional Index by Welles Wilder	<u>Technical Indicators</u>
<u>iAlligator</u>	Alligator	<u>Technical Indicators</u>
<u>iAMA</u>	Adaptive Moving Average	<u>Technical Indicators</u>
<u>iAO</u>	Awesome Oscillator	<u>Technical Indicators</u>
<u>iATR</u>	Average True Range	<u>Technical Indicators</u>
<u>iBands</u>	Bollinger Bands®	<u>Technical Indicators</u>
<u>iBearsPower</u>	Bears Power	<u>Technical Indicators</u>
<u>iBullsPower</u>	Bulls Power	<u>Technical Indicators</u>
<u>iBWMFI</u>	Market Facilitation Index by Bill Williams	<u>Technical Indicators</u>
<u>iCCI</u>	Commodity Channel Index	<u>Technical Indicators</u>
<u>iChaikin</u>	Chaikin Oscillator	<u>Technical Indicators</u>
<u>iCustom</u>	Custom indicator	<u>Technical Indicators</u>
<u>iDEMA</u>	Double Exponential Moving Average	<u>Technical Indicators</u>
<u>iDeMarker</u>	DeMarker	<u>Technical Indicators</u>
<u>iEnvelopes</u>	Envelopes	<u>Technical Indicators</u>
<u>iForce</u>	Force Index	<u>Technical Indicators</u>
<u>iFractals</u>	Fractals	<u>Technical Indicators</u>
<u>iFrAMA</u>	Fractal Adaptive Moving Average	<u>Technical Indicators</u>
<u>iGator</u>	Gator Oscillator	<u>Technical Indicators</u>
<u>ilchimoku</u>	Ichimoku Kinko Hyo	<u>Technical Indicators</u>
<u>iMA</u>	Moving Average	<u>Technical Indicators</u>
<u>iMACD</u>	Moving Averages Convergence-Divergence	<u>Technical Indicators</u>
<u>iMFI</u>	Money Flow Index	<u>Technical Indicators</u>
<u>iMomentum</u>	Momentum	<u>Technical Indicators</u>
<u>IndicatorCreate</u>	Returns the handle to the specified technical indicator	<u>Timeseries and Indicators Access</u>

	created by an array of MqlParam type parameters	
IndicatorParameters	Based on the specified handle, returns the number of input parameters of the indicator, as well as the values and types of the parameters	Timeseries and Indicators Access
IndicatorRelease	Removes an indicator handle and releases the calculation block of the indicator, if it's not used by anyone else	Timeseries and Indicators Access
IndicatorSetDouble	Sets the value of an indicator property of the double type	Custom Indicators
IndicatorSetInteger	Sets the value of an indicator property of the int type	Custom Indicators
IndicatorSetString	Sets the value of an indicator property of the string type	Custom Indicators
IntegerToString	Converting int into a string of preset length	Conversion Functions
iOBV	On Balance Volume	Technical Indicators
iOsMA	Moving Average of Oscillator (MACD histogram)	Technical Indicators
iRSI	Relative Strength Index	Technical Indicators
iRVI	Relative Vigor Index	Technical Indicators
iSAR	Parabolic Stop And Reverse System	Technical Indicators
IsStopped	Returns true, if an mql5 program has been commanded to stop its operation	Checkup
iStdDev	Standard Deviation	Technical Indicators
iStochastic	Stochastic Oscillator	Technical Indicators
iTEMA	Triple Exponential Moving Average	Technical Indicators
iTriX	Triple Exponential Moving Averages Oscillator	Technical Indicators
iVIDyA	Variable Index Dynamic Average	Technical Indicators
iVolumes	Volumes	Technical Indicators
iWPR	Williams' Percent Range	Technical Indicators

<u>log</u>	Returns natural logarithm	<u>Math Functions</u>
<u>log10</u>	Returns the logarithm of a number by base 10	<u>Math Functions</u>
<u>MarketBookAdd</u>	Provides opening of Depth of Market for a selected symbol, and subscribes for receiving notifications of the DOM changes	<u>Market Info</u>
<u>MarketBookGet</u>	Returns a structure array <u>MqlBookInfo</u> containing records of the Depth of Market of a specified symbol	<u>Market Info</u>
<u>MarketBookRelease</u>	Provides closing of Depth of Market for a selected symbol, and cancels the subscription for receiving notifications of the DOM changes	<u>Market Info</u>
<u>MathAbs</u>	Returns absolute value (modulus) of the specified numeric value	<u>Math Functions</u>
<u>MathArccos</u>	Returns the arc cosine of x in radians	<u>Math Functions</u>
<u>MathArcsin</u>	Returns the arc sine of x in radians	<u>Math Functions</u>
<u>MathArctan</u>	Returns the arc tangent of x in radians	<u>Math Functions</u>
<u>MathCeil</u>	Returns integer numeric value closest from above	<u>Math Functions</u>
<u>MathCos</u>	Returns the cosine of a number	<u>Math Functions</u>
<u>MathExp</u>	Returns exponent of a number	<u>Math Functions</u>
<u>MathFloor</u>	Returns integer numeric value closest from below	<u>Math Functions</u>
<u>MathIsValidNumber</u>	Checks the correctness of a real number	<u>Math Functions</u>
<u>MathLog</u>	Returns natural logarithm	<u>Math Functions</u>
<u>MathLog10</u>	Returns the logarithm of a number by base 10	<u>Math Functions</u>
<u>MathMax</u>	Returns the maximal value of the two numeric values	<u>Math Functions</u>

<u>MathMin</u>	Returns the minimal value of the two numeric values	<u>Math Functions</u>
<u>MathMod</u>	Returns the real remainder after the division of two numbers	<u>Math Functions</u>
<u>MathPow</u>	Raises the base to the specified power	<u>Math Functions</u>
<u>MathRand</u>	Returns a pseudorandom value within the range of 0 to 32767	<u>Math Functions</u>
<u>MathRound</u>	Rounds of a value to the nearest integer	<u>Math Functions</u>
<u>MathSin</u>	Returns the sine of a number	<u>Math Functions</u>
<u>MathSqrt</u>	Returns a square root	<u>Math Functions</u>
<u>MathSrand</u>	Sets the starting point for generating a series of pseudorandom integers	<u>Math Functions</u>
<u>MathTan</u>	Returns the tangent of a number	<u>Math Functions</u>
<u>MessageBox</u>	Creates, displays a message box and manages it	<u>Common Functions</u>
<u>MQLInfoInteger</u>	Returns an integer value of a corresponding property of a running mql5 program	<u>Checkup</u>
<u>MQLInfoString</u>	Returns a string value of a corresponding property of a running mql5 program	<u>Checkup</u>
<u>NormalizeDouble</u>	Rounding of a floating point number to a specified accuracy	<u>Conversion Functions</u>
<u>ObjectCreate</u>	Creates an object of the specified type in a specified chart	<u>Object Functions</u>
<u>ObjectDelete</u>	Removes the object with the specified name from the specified chart (from the specified chart subwindow)	<u>Object Functions</u>
<u>ObjectFind</u>	Searches for an object with the specified ID by the name	<u>Object Functions</u>
<u>ObjectGetDouble</u>	Returns the double value of the corresponding object property	<u>Object Functions</u>

<u>ObjectGetInteger</u>	Returns the integer value of the corresponding object property	<u>Object Functions</u>
<u>ObjectGetString</u>	Returns the string value of the corresponding object property	<u>Object Functions</u>
<u>ObjectGetTimeByValue</u>	Returns the time value for the specified object price value	<u>Object Functions</u>
<u>ObjectGetValueByTime</u>	Returns the price value of an object for the specified time	<u>Object Functions</u>
<u>ObjectMove</u>	Changes the coordinates of the specified object anchor point	<u>Object Functions</u>
<u>ObjectName</u>	Returns the name of an object of the corresponding type in the specified chart (specified chart subwindow)	<u>Object Functions</u>
<u>ObjectsDeleteAll</u>	Removes all objects of the specified type from the specified chart (from the specified chart subwindow)	<u>Object Functions</u>
<u>ObjectSetDouble</u>	Sets the value of the corresponding object property	<u>Object Functions</u>
<u>ObjectSetInteger</u>	Sets the value of the corresponding object property	<u>Object Functions</u>
<u>ObjectSetString</u>	Sets the value of the corresponding object property	<u>Object Functions</u>
<u>ObjectsTotal</u>	Returns the number of objects of the specified type in the specified chart (specified chart subwindow)	<u>Object Functions</u>
<u>OrderCalcMargin</u>	Calculates the margin required for the specified order type, in the deposit currency	<u>Trade Functions</u>
<u>OrderCalcProfit</u>	Calculates the profit based on the parameters passed, in the deposit currency	<u>Trade Functions</u>
<u>OrderCheck</u>	Checks if there are enough funds to execute the required <u>trade operation</u> .	<u>Trade Functions</u>
<u>OrderGetDouble</u>	Returns the requested property of the order (double)	<u>Trade Functions</u>

OrderGetInteger	Returns the requested property of the order (datetime or int)	Trade Functions
OrderGetString	Returns the requested property of the order (string)	Trade Functions
OrderGetTicket	Return the ticket of a corresponding order	Trade Functions
OrderSelect	Selects a order for further working with it	Trade Functions
OrderSend	Sends trade requests to a server	Trade Functions
OrderSendAsync	Asynchronously sends trade requests without waiting for the trade response of the trade server	Trade Functions
OrdersTotal	Returns the number of orders	Trade Functions
ParameterGetRange	Receives data on the values range and the change step for an input variable when optimizing an Expert Advisor in the Strategy Tester	Working with Optimization Results
ParameterSetRange	Specifies the use of input variable when optimizing an Expert Advisor in the Strategy Tester: value, change step, initial and final values	Working with Optimization Results
Period	Returns the current chart timeframe	Checkup
PeriodSeconds	Returns the number of seconds in the period	Common Functions
PlaySound	Plays a sound file	Common Functions
PlotIndexGetInteger	Returns the value of an indicator line property of the integer type	Custom Indicators
PlotIndexSetDouble	Sets the value of an indicator line property of the type double	Custom Indicators
PlotIndexSetInteger	Sets the value of an indicator line property of the int type	Custom Indicators
PlotIndexSetString	Sets the value of an indicator line property of the string type	Custom Indicators

<u>Point</u>	Returns the point size of the current symbol in the quote currency	<u>Checkup</u>
<u>PositionGetDouble</u>	Returns the requested property of an open position (double)	<u>Trade Functions</u>
<u>PositionGetInteger</u>	Returns the requested property of an open position (datetime or int)	<u>Trade Functions</u>
<u>PositionGetString</u>	Returns the requested property of an open position (string)	<u>Trade Functions</u>
<u>PositionGetSymbol</u>	Returns the symbol corresponding to the open position	<u>Trade Functions</u>
<u>PositionGetTicket</u>	Returns the ticket of the position with the specified index in the list of open positions	<u>Trade Functions</u>
<u>PositionSelect</u>	Chooses an open position for further working with it	<u>Trade Functions</u>
<u>PositionSelectByTicket</u>	Selects a position to work with by the ticket number specified in it	<u>Trade Functions</u>
<u>PositionsTotal</u>	Returns the number of open positions	<u>Trade Functions</u>
<u>pow</u>	Raises the base to the specified power	<u>Math Functions</u>
<u>Print</u>	Displays a message in the log	<u>Common Functions</u>
<u>PrintFormat</u>	Formats and prints the sets of symbols and values in a log file in accordance with a preset format	<u>Common Functions</u>
<u>rand</u>	Returns a pseudorandom value within the range of 0 to 32767	<u>Math Functions</u>
<u>ResetLastError</u>	Sets the value of a predetermined variable <u>LastError</u> to zero	<u>Common Functions</u>
<u>ResourceCreate</u>	Creates an image resource based on a data set	<u>Common Functions</u>

<u>ResourceFree</u>	Deletes <u>dynamically created resource</u> (freeing the memory allocated for it)	<u>Common Functions</u>
<u>ResourceReadImage</u>	Reads data from the graphical resource <u>created by ResourceCreate() function</u> or <u>saved in EX5 file during compilation</u>	<u>Common Functions</u>
<u>ResourceSave</u>	Saves a resource into the specified file	<u>Common Functions</u>
<u>round</u>	Rounds of a value to the nearest integer	<u>Math Functions</u>
<u>SendFTP</u>	Sends a file at the address specified in the settings window of the "FTP" tab	<u>Common Functions</u>
<u>SendMail</u>	Sends an email at the address specified in the settings window of the "Email" tab	<u>Common Functions</u>
<u>SendNotification</u>	Sends push notifications to mobile terminals, whose MetaQuotes ID are specified in the "Notifications" tab	<u>Common Functions</u>
<u>SeriesInfoInteger</u>	Returns information about the state of historical data	<u>Timeseries and Indicators Access</u>
<u>SetIndexBuffer</u>	Binds the specified indicator buffer with one-dimensional dynamic <u>array</u> of the <u>double</u> type	<u>Custom Indicators</u>
<u>ShortArrayToString</u>	Copying array part into a string	<u>Conversion Functions</u>
<u>ShortToString</u>	Converting symbol code (unicode) into one-symbol string	<u>Conversion Functions</u>
<u>SignalBaseGetDouble</u>	Returns the value of double type property for selected signal	<u>Trade Signals</u>
<u>SignalBaseGetInteger</u>	Returns the value of integer type property for selected signal	<u>Trade Signals</u>
<u>SignalBaseGetString</u>	Returns the value of string type property for selected signal	<u>Trade Signals</u>

<u>SignalBaseSelect</u>	Selects a signal from signals, available in terminal for further working with it	<u>Trade Signals</u>
<u>SignalBaseTotal</u>	Returns the total amount of signals, available in terminal	<u>Trade Signals</u>
<u>SignalInfoGetDouble</u>	Returns the value of double type property of signal copy settings	<u>Trade Signals</u>
<u>SignalInfoGetInteger</u>	Returns the value of integer type property of signal copy settings	<u>Trade Signals</u>
<u>SignalInfoGetString</u>	Returns the value of string type property of signal copy settings	<u>Trade Signals</u>
<u>SignalInfoSetDouble</u>	Sets the value of double type property of signal copy settings	<u>Trade Signals</u>
<u>SignalInfoSetInteger</u>	Sets the value of integer type property of signal copy settings	<u>Trade Signals</u>
<u>SignalSubscribe</u>	Subscribes to the trading signal	<u>Trade Signals</u>
<u>SignalUnsubscribe</u>	Cancels subscription	<u>Trade Signals</u>
<u>sin</u>	Returns the sine of a number	<u>Math Functions</u>
<u>Sleep</u>	Suspends execution of the current Expert Advisor or script within a specified interval	<u>Common Functions</u>
<u>sqrt</u>	Returns a square root	<u>Math Functions</u>
<u>srand</u>	Sets the starting point for generating a series of pseudorandom integers	<u>Math Functions</u>
<u>StringAdd</u>	Adds a string to the end of another string	<u>String Functions</u>
<u>StringBufferLen</u>	Returns the size of buffer allocated for the string	<u>String Functions</u>
<u>StringCompare</u>	Compares two strings and returns 1 if the first string is greater than the second; 0 - if the strings are equal; -1	<u>String Functions</u>

	(minus 1) - if the first string is less than the second one	
<u>StringConcatenate</u>	Forms a string of parameters passed	<u>String Functions</u>
<u>StringFill</u>	Fills out a specified string by selected symbols	<u>String Functions</u>
<u>StringFind</u>	Search for a substring in a string	<u>String Functions</u>
<u>StringFormat</u>	Converting number into string according to preset format	<u>Conversion Functions</u>
<u>StringGetCharacter</u>	Returns the value of a number located in the specified string position	<u>String Functions</u>
<u>StringInit</u>	Initializes string by specified symbols and provides the specified string length	<u>String Functions</u>
<u>StringLen</u>	Returns the number of symbols in a string	<u>String Functions</u>
<u>StringReplace</u>	Replaces all the found substrings of a string by a set sequence of symbols	<u>String Functions</u>
<u>StringSetCharacter</u>	Returns a copy of a string with a changed value of a symbol in a specified position	<u>String Functions</u>
<u>StringSplit</u>	Gets substrings by a specified separator from the specified string, returns the number of substrings obtained	<u>String Functions</u>
<u>StringSubstr</u>	Extracts a substring from a text string starting from a specified position	<u>String Functions</u>
<u>StringToCharArray</u>	Symbol-wise copying a string converted from Unicode to ANSI, to a selected place of array of uchar type	<u>Conversion Functions</u>
<u>StringToColor</u>	Converting "R,G,B" string or string with color name into color type value	<u>Conversion Functions</u>
<u>StringToDouble</u>	Converting a string containing a symbol representation of number into number of double type	<u>Conversion Functions</u>

<u>StringToInteger</u>	Converting a string containing a symbol representation of number into number of int type	<u>Conversion Functions</u>
<u>StringToLower</u>	Transforms all symbols of a selected string to lowercase	<u>String Functions</u>
<u>StringToShortArray</u>	Symbol-wise copying a string to a selected part of array of ushort type	<u>Conversion Functions</u>
<u>StringToTime</u>	Converting a string containing time or date in "yyyy.mm.dd [hh:mi]" format into datetime type	<u>Conversion Functions</u>
<u>StringToUpper</u>	Transforms all symbols of a selected string into capitals	<u>String Functions</u>
<u>StringTrimLeft</u>	Cuts line feed characters, spaces and tabs in the left part of the string	<u>String Functions</u>
<u>StringTrimRight</u>	Cuts line feed characters, spaces and tabs in the right part of the string	<u>String Functions</u>
<u>StructToTime</u>	Converts a variable of MqlDateTime structure type into a datetime value	<u>Date and Time</u>
<u>Symbol</u>	Returns the name of a symbol of the current chart	<u>Checkup</u>
<u>SymbolInfoDouble</u>	Returns the double value of the symbol for the corresponding property	<u>Market Info</u>
<u>SymbolInfoInteger</u>	Returns a value of an integer type (long, datetime, int or bool) of a specified symbol for the corresponding property	<u>Market Info</u>
<u>SymbolInfoMarginRate</u>	Returns the margin rates depending on the order type and direction	<u>Market Info</u>
<u>SymbolInfoSessionQuote</u>	Allows receiving time of beginning and end of the specified quoting sessions for a specified symbol and day of week.	<u>Market Info</u>

<u>SymbolInfoSessionTrade</u>	Allows receiving time of beginning and end of the specified trading sessions for a specified symbol and day of week.	<u>Market Info</u>
<u>SymbolInfoString</u>	Returns a value of the string type of a specified symbol for the corresponding property	<u>Market Info</u>
<u>SymbolInfoTick</u>	Returns the current prices for the specified symbol in a variable of the <u>MqlTick</u> type	<u>Market Info</u>
<u>SymbolsSynchronized</u>	Checks whether data of a selected symbol in the terminal are <u>synchronized</u> with data on the trade server	<u>Market Info</u>
<u>SymbolName</u>	Returns the name of a specified symbol	<u>Market Info</u>
<u>SymbolSelect</u>	Selects a symbol in the Market Watch window or removes a symbol from the window	<u>Market Info</u>
<u>SymbolsTotal</u>	Returns the number of available (selected in Market Watch or all) symbols	<u>Market Info</u>
<u>tan</u>	Returns the tangent of a number	<u>Math Functions</u>
<u>TerminalClose</u>	Commands the terminal to complete operation	<u>Common Functions</u>
<u>TerminalInfoDouble</u>	Returns an double value of a corresponding property of the mql5 program environment	<u>Checkup</u>
<u>TerminalInfoInteger</u>	Returns an integer value of a corresponding property of the mql5 program environment	<u>Checkup</u>
<u>TerminalInfoString</u>	Returns a string value of a corresponding property of the mql5 program environment	<u>Checkup</u>
<u>TesterStatistics</u>	It returns the value of a specified statistic calculated based on testing results	<u>Common Functions</u>
<u>TextGetSize</u>	Returns the string's width and height at the current <u>font settings</u>	<u>Object Functions</u>

<u>TextOut</u>	Transfers the text to the custom array (buffer) designed for creation of a graphical <u>resource</u>	<u>Object Functions</u>
<u>TextSetFont</u>	Sets the font for displaying the text using drawing methods (Arial 20 used by default)	<u>Object Functions</u>
<u>TimeCurrent</u>	Returns the last known server time (time of the last quote receipt) in the datetime format	<u>Date and Time</u>
<u>TimeDaylightSavings</u>	Returns the sign of Daylight Saving Time switch	<u>Date and Time</u>
<u>TimeGMT</u>	Returns GMT in datetime format with the Daylight Saving Time by local time of the computer, where the client terminal is running	<u>Date and Time</u>
<u>TimeGMTOffset</u>	Returns the current difference between GMT time and the local computer time in seconds, taking into account DST switch	<u>Date and Time</u>
<u>TimeLocal</u>	Returns the local computer time in datetime format	<u>Date and Time</u>
<u>TimeToString</u>	Converting a value containing time in seconds elapsed since 01.01.1970 into a string of "yyyy.mm.dd hh:mi" format	<u>Conversion Functions</u>
<u>TimeToStruct</u>	Converts a datetime value into a variable of MqlDateTime structure type	<u>Date and Time</u>
<u>TimeTradeServer</u>	Returns the current calculation time of the trade server	<u>Date and Time</u>
<u>UninitializeReason</u>	Returns the code of the reason for deinitialization	<u>Checkup</u>
<u>WebRequest</u>	Sends HTTP request to the specified server	<u>Common Functions</u>
<u>ZeroMemory</u>	Resets a variable passed to it by reference. The variable can be of any type, except for classes and structures that have constructors.	<u>Common Functions</u>

List of MQL5 Constants

All MQL5 constants in alphabetical order.

Constant	Description	Usage
__DATE__	File compilation date without time (hours, minutes and seconds are equal to 0)	Print
__DATETIME__	File compilation date and time	Print
__FILE__	Name of the currently compiled file	Print
__FUNCSIG__	Signature of the function in whose body the macro is located. Logging of the full description of functions can be useful in the identification of overloaded functions	Print
__FUNCTION__	Name of the function, in whose body the macro is located	Print
__LINE__	Line number in the source code, in which the macro is located	Print
__MQLBUILD__, __MQL5BUILD__	Compiler build number	Print
__PATH__	An absolute path to the file that is currently being compiled	Print
ACCOUNT_ASSETS	The current assets of an account	AccountInfoDouble
ACCOUNT_BALANCE	Account balance in the deposit currency	AccountInfoDouble
ACCOUNT_COMMISSION_BLOCKED	The current blocked commission amount on an account	AccountInfoDouble
ACCOUNT_COMPANY	Name of a company that serves the account	AccountInfoString
ACCOUNT_CREDIT	Account credit in the deposit currency	AccountInfoDouble
ACCOUNT_CURRENCY	Account currency	AccountInfoString

ACCOUNT_EQUITY	Account equity in the deposit currency	AccountInfoDouble
ACCOUNT_LEVERAGE	Account leverage	AccountInfoInteger
ACCOUNT_LIABILITIES	The current liabilities on an account	AccountInfoDouble
ACCOUNT_LIMIT_ORDERS	Maximum allowed number of active pending orders	AccountInfoInteger
ACCOUNT_LOGIN	Account number	AccountInfoInteger
ACCOUNT_MARGIN	Account margin used in the deposit currency	AccountInfoDouble
ACCOUNT_MARGIN_FREE	Free margin of an account in the deposit currency	AccountInfoDouble
ACCOUNT_MARGIN_INITIAL	Initial margin. The amount reserved on an account to cover the margin of all pending orders	AccountInfoDouble
ACCOUNT_MARGIN_LEVEL	Account margin level in percents	AccountInfoDouble
ACCOUNT_MARGIN_MAINTENANCE	Maintenance margin. The minimum equity reserved on an account to cover the minimum amount of all open positions	AccountInfoDouble
ACCOUNT_MARGIN_SO_CALL	Margin call level. Depending on the set ACCOUNT_MARGIN_SO_MODE is expressed in percents or in the deposit currency	AccountInfoDouble
ACCOUNT_MARGIN_SO_MODE	Mode for setting the minimal allowed margin	AccountInfoInteger
ACCOUNT_MARGIN_SO_SO	Margin stop out level. Depending on the set ACCOUNT_MARGIN_SO_MODE is expressed in percents or in the deposit currency	AccountInfoDouble
ACCOUNT_NAME	Client name	AccountInfoString
ACCOUNT_PROFIT	Current profit of an account in the deposit currency	AccountInfoDouble
ACCOUNT_SERVER	Trade server name	AccountInfoString
ACCOUNT_STOPOUT_MODE_MONEY	Account stop out mode in money	AccountInfoInteger

ACCOUNT_STOPOUT_MODE_PERCENT	Account stop out mode in percents	AccountInfoInteger
ACCOUNT_TRADE_ALLOWED	Allowed trade for the current account	AccountInfoInteger
ACCOUNT_TRADE_EXPERT	Allowed trade for an Expert Advisor	AccountInfoInteger
ACCOUNT_TRADE_MODE	Account trade mode	AccountInfoInteger
ACCOUNT_TRADE_MODE_CONTEST	Contest account	AccountInfoInteger
ACCOUNT_TRADE_MODE_DEMO	Demo account	AccountInfoInteger
ACCOUNT_TRADE_MODE_REAL	Real account	AccountInfoInteger
ALIGN_CENTER	Centered (only for the Edit object)	ObjectSetInteger , ObjectGetInteger , ChartScreenShot
ALIGN_LEFT	Left alignment	ObjectSetInteger , ObjectGetInteger , ChartScreenShot
ALIGN_RIGHT	Right alignment	ObjectSetInteger , ObjectGetInteger , ChartScreenShot
ANCHOR_CENTER	Anchor point strictly in the center of the object	ObjectSetInteger , ObjectGetInteger
ANCHOR_LEFT	Anchor point to the left in the center	ObjectSetInteger , ObjectGetInteger
ANCHOR_LEFT_LOWER	Anchor point at the lower left corner	ObjectSetInteger , ObjectGetInteger
ANCHOR_LEFT_UPPER	Anchor point at the upper left corner	ObjectSetInteger , ObjectGetInteger
ANCHOR_LOWER	Anchor point below in the center	ObjectSetInteger , ObjectGetInteger
ANCHOR_RIGHT	Anchor point to the right in the center	ObjectSetInteger , ObjectGetInteger
ANCHOR_RIGHT_LOWER	Anchor point at the lower right corner	ObjectSetInteger , ObjectGetInteger
ANCHOR_RIGHT_UPPER	Anchor point at the upper right corner	ObjectSetInteger , ObjectGetInteger
ANCHOR_UPPER	Anchor point above in the center	ObjectSetInteger , ObjectGetInteger

BASE_LINE	Main line	Indicators Lines
BOOK_TYPE_BUY	Buy order (Bid)	MqlBookInfo
BOOK_TYPE_BUY_MARKET	Buy order by Market	MqlBookInfo
BOOK_TYPE_SELL	Sell order (Offer)	MqlBookInfo
BOOK_TYPE_SELL_MARKET	Sell order by Market	MqlBookInfo
BORDER_FLAT	Flat form	ObjectSetInteger , ObjectGetInteger
BORDER_RAISED	Prominent form	ObjectSetInteger , ObjectGetInteger
BORDER_SUNKEN	Concave form	ObjectSetInteger , ObjectGetInteger
CHAR_MAX	Maximal value, which can be represented by char type	Numerical Type Constants
CHAR_MIN	Minimal value, which can be represented by char type	Numerical Type Constants
CHART_AUTOSCROLL	Mode of automatic moving to the right border of the chart	ChartSetInteger , ChartGetInteger
CHART_BARS	Display as a sequence of bars	ChartSetInteger
CHART_BEGIN	Chart beginning (the oldest prices)	ChartNavigate
CHART_BRING_TO_TOP	Show chart on top of other charts	ChartSetInteger , ChartGetInteger
CHART_CANDLES	Display as Japanese candlesticks	ChartSetInteger
CHART_COLOR_ASK	Ask price level color	ChartSetInteger , ChartGetInteger
CHART_COLOR_BACKGROUND	Chart background color	ChartSetInteger , ChartGetInteger
CHART_COLOR_BID	Bid price level color	ChartSetInteger , ChartGetInteger
CHART_COLOR_CANDLE_BEAR	Body color of a bear candlestick	ChartSetInteger , ChartGetInteger
CHART_COLOR_CANDLE_BULL	Body color of a bull candlestick	ChartSetInteger , ChartGetInteger
CHART_COLOR_CHART_DOWN	Color for the down bar, shadows and body borders of bear candlesticks	ChartSetInteger , ChartGetInteger

<u>CHART_COLOR_CHART_LINE</u>	Line chart color and color of "Doji" Japanese candlesticks	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_COLOR_CHART_UP</u>	Color for the up bar, shadows and body borders of bull candlesticks	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_COLOR_FOREGROUND</u>	Color of axes, scales and OHLC line	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_COLOR_GRID</u>	Grid color	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_COLOR_LAST</u>	Line color of the last executed deal price (Last)	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_COLOR_STOP_LEVEL</u>	Color of stop order levels (Stop Loss and Take Profit)	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_COLOR_VOLUME</u>	Color of volumes and position opening levels	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_COMMENT</u>	Text of a comment in a chart	<u>ChartSetString</u> , <u>ChartGetString</u>
CHART_CURRENT_POS	Current position	<u>ChartNavigate</u>
<u>CHART_DRAG_TRADE_LEVELS</u>	Permission to drag trading levels on a chart with a mouse. The drag mode is enabled by default (true value)	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_EVENT_MOUSE_MOVE</u>	Send notifications of mouse move and mouse click events (<u>CHARTEVENT_MOUSE_MOVE</u>) to all mql5 programs on a chart	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_EVENT_OBJECT_CREATE</u>	Send a notification of an event of new object creation (<u>CHARTEVENT_OBJECT_CREATE</u>) to all mql5-programs on a chart	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_EVENT_OBJECT_DELETE</u>	Send a notification of an event of object deletion (<u>CHARTEVENT_OBJECT_DELETE</u>) to all mql5-programs on a chart	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_FIRST_VISIBLE_BAR</u>	Number of the first visible bar in the chart. Indexing of bars is the same as for <u>timeseries</u> .	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_FIXED_MAX</u>	Fixed chart maximum	<u>ChartSetDouble</u> , <u>ChartGetDouble</u>

<u>CHART_FIXED_MIN</u>	Fixed chart minimum	<u>ChartSetDouble</u> , <u>ChartGetDouble</u>
<u>CHART_FIXED_POSITION</u>	Chart fixed position from the left border in percent value. Chart fixed position is marked by a small gray triangle on the horizontal time axis. It is displayed only if the automatic chart scrolling to the right on tick incoming is disabled (see <u>CHART_AUTOSCROLL</u> property). The bar on a fixed position remains in the same place when zooming in and out.	<u>ChartSetDouble</u> , <u>ChartGetDouble</u>
<u>CHART_FOREGROUND</u>	Price chart in the foreground	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_HEIGHT_IN_PIXELS</u>	Chart height in pixels	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_IS_OBJECT</u>	Identifying "Chart" (<u>OBJ_CHART</u>) object - returns true for a graphical object. Returns false for a real chart	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_LINE</u>	Display as a line drawn by Close prices	<u>ChartSetInteger</u>
<u>CHART_MODE</u>	Chart type (candlesticks, bars or line)	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_MOUSE_SCROLL</u>	Scrolling the chart horizontally using the left mouse button. Vertical scrolling is also available if the value of any following properties is set to true: <u>CHART_SCALEFIX</u> , <u>CHART_SCALEFIX_11</u> or <u>CHART_SCALE_PT_PER_BAR</u>	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_POINTS_PER_BAR</u>	Scale in points per bar	<u>ChartSetDouble</u> , <u>ChartGetDouble</u>
<u>CHART_PRICE_MAX</u>	Chart maximum	<u>ChartSetDouble</u> , <u>ChartGetDouble</u>
<u>CHART_PRICE_MIN</u>	Chart minimum	<u>ChartSetDouble</u> , <u>ChartGetDouble</u>

<u>CHART_SCALE</u>	Scale	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_SCALE_PT_PER_BAR</u>	Scale to be specified in points per bar	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_SCALEFIX</u>	Fixed scale mode	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_SCALEFIX_11</u>	Scale 1:1 mode	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_SHIFT</u>	Mode of price chart indent from the right border	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_SHIFT_SIZE</u>	The size of the zero bar indent from the right border in percents	<u>ChartSetDouble</u> , <u>ChartGetDouble</u>
<u>CHART_SHOW_ASK_LINE</u>	Display Ask values as a horizontal line in a chart	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_SHOW_BID_LINE</u>	Display Bid values as a horizontal line in a chart	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_SHOW_DATE_SCALE</u>	Showing the time scale on a chart	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_SHOW_GRID</u>	Display grid in the chart	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_SHOW_LAST_LINE</u>	Display Last values as a horizontal line in a chart	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_SHOW_OBJECT_DESCR</u>	Pop-up descriptions of graphical objects	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_SHOW_OHLC</u>	Show OHLC values in the upper left corner	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_SHOW_ONE_CLICK</u>	Showing the " <u>One click trading</u> " panel on a chart	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_SHOW_PERIOD_SEP</u>	Display vertical separators between adjacent periods	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_SHOW_PRICE_SCALE</u>	Showing the price scale on a chart	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_SHOW_TRADE_LEVELS</u>	Displaying trade levels in the chart (levels of open positions, Stop Loss, Take Profit and pending orders)	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_SHOW_VOLUMES</u>	Display volume in the chart	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>

<u>CHART_VISIBLE_BARS</u>	The number of bars on the chart that can be displayed	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
CHART_VOLUME_HIDE	Volumes are not shown	<u>ChartSetInteger</u>
CHART_VOLUME_REAL	Trade volumes	<u>ChartSetInteger</u>
CHART_VOLUME_TICK	Tick volumes	<u>ChartSetInteger</u>
<u>CHART_WIDTH_IN_BARS</u>	Chart width in bars	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_WIDTH_IN_PIXELS</u>	Chart width in pixels	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_WINDOW_HANDLE</u>	Chart window handle (HWND)	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_WINDOW_IS_VISIBLE</u>	Visibility of subwindows	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_WINDOW_YDISTANCE</u>	<p>The distance between the upper frame of the indicator subwindow and the upper frame of the main chart window, along the vertical Y axis, in pixels. In case of a mouse event, the cursor coordinates are passed in terms of the coordinates of the main chart window, while the coordinates of graphical objects in an indicator subwindow are set relative to the upper left corner of the subwindow.</p> <p>The value is required for converting the absolute coordinates of the main chart to the local coordinates of a subwindow for correct work with the graphical objects, whose coordinates are set relative to the upper left corner of the subwindow frame.</p>	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
<u>CHART_WINDOWS_TOTAL</u>	The total number of chart windows, including indicator subwindows	<u>ChartSetInteger</u> , <u>ChartGetInteger</u>
CHARTEVENT_CHART_CHANGE	Change of the chart size or modification of chart	<u>OnChartEvent</u>

	properties through the Properties dialog	
CHARTEVENT_CLICK	Clicking on a chart	OnChartEvent
CHARTEVENT_CUSTOM	Initial number of an event from a range of custom events	OnChartEvent
CHARTEVENT_CUSTOM_LAST	The final number of an event from a range of custom events	OnChartEvent
CHARTEVENT_KEYDOWN	Keystrokes	OnChartEvent
CHARTEVENT_MOUSE_MOVE	Mouse move, mouse clicks (if CHART_EVENT_MOUSE_MOVE =true is set for the chart)	OnChartEvent
CHARTEVENT_OBJECT_CHANGE	Graphical object property changed via the properties dialog	OnChartEvent
CHARTEVENT_OBJECT_CLICK	Clicking on a graphical object	OnChartEvent
CHARTEVENT_OBJECT_CREATE	Graphical object created (if CHART_EVENT_OBJECT_CREATE =true is set for the chart)	OnChartEvent
CHARTEVENT_OBJECT_DELETE	Graphical object deleted (if CHART_EVENT_OBJECT_DELETE =true is set for the chart)	OnChartEvent
CHARTEVENT_OBJECT_DRAG	Drag and drop of a graphical object	OnChartEvent
CHARTEVENT_OBJECT_ENDEDIT	End of text editing in the graphical object Edit	OnChartEvent
CHARTS_MAX	The maximum possible number of simultaneously open charts in the terminal	Other Constants
CHIKOSPAN_LINE	Chikou Span line	Indicators Lines
clrAliceBlue	Alice Blue	Web Colors
clrAntiqueWhite	Antique White	Web Colors
clrAqua	Aqua	Web Colors
clrAquamarine	Aquamarine	Web Colors
clrBeige	Beige	Web Colors
clrBisque	Bisque	Web Colors
clrBlack	Black	Web Colors
clrBlanchedAlmond	Blanched Almond	Web Colors

clrBlue	Blue	Web Colors
clrBlueViolet	Blue Violet	Web Colors
clrBrown	Brown	Web Colors
clrBurlyWood	Burly Wood	Web Colors

clrYellow	Yellow	Web Colors

clrYellowGreen	Yellow Green	Web Colors
CORNER_LEFT_LOWER	Center of coordinates is in the lower left corner of the chart	ObjectSetInteger , ObjectGetInteger
CORNER_LEFT_UPPER	Center of coordinates is in the upper left corner of the chart	ObjectSetInteger , ObjectGetInteger
CORNER_RIGHT_LOWER	Center of coordinates is in the lower right corner of the chart	ObjectSetInteger , ObjectGetInteger
CORNER_RIGHT_UPPER	Center of coordinates is in the upper right corner of the chart	ObjectSetInteger , ObjectGetInteger
CP_ACP	The current Windows ANSI code page.	CharArrayToString , StringToCharArray , FileOpen
CP_MACCP	The current system Macintosh code page. Note: This value is mostly used in earlier created program codes and is of no use now, since modern Macintosh computers use Unicode for encoding.	CharArrayToString , StringToCharArray , FileOpen
CP_OEMCP	The current system OEM code page.	CharArrayToString , StringToCharArray , FileOpen
CP_SYMBOL	Symbol code page	CharArrayToString , StringToCharArray , FileOpen
CP_THREAD_ACP	The Windows ANSI code page for the current thread.	CharArrayToString , StringToCharArray , FileOpen
CP_UTF7	UTF-7 code page.	CharArrayToString , StringToCharArray , FileOpen
CP_UTF8	UTF-8 code page.	CharArrayToString , StringToCharArray , FileOpen
CRYPT_AES128	AES encryption with 128 bit key (16 bytes)	CryptEncode , CryptDecode
CRYPT_AES256	AES encryption with 256 bit key (32 bytes)	CryptEncode , CryptDecode
CRYPT_ARCH_ZIP	ZIP archives	CryptEncode , CryptDecode
CRYPT_BASE64	BASE64	CryptEncode , CryptDecode
CRYPT_DES	DES encryption with 56 bit key (7 bytes)	CryptEncode , CryptDecode
CRYPT_HASH_MD5	MD5 HASH calculation	CryptEncode , CryptDecode
CRYPT_HASH_SHA1	SHA1 HASH calculation	CryptEncode , CryptDecode

CRYPT_HASH_SHA256	SHA256 HASH calculation	CryptEncode , CryptDecode
DBL_DIG	Number of significant decimal digits for double type	Numerical Type Constants
DBL_EPSILON	Minimal value, which satisfies the condition: $1.0 + \text{DBL_EPSILON} \neq 1.0$ (for double type)	Numerical Type Constants
DBL_MANT_DIG	Bits count in a mantissa for double type	Numerical Type Constants
DBL_MAX	Maximal value, which can be represented by double type	Numerical Type Constants
DBL_MAX_10_EXP	Maximal decimal value of exponent degree for double type	Numerical Type Constants
DBL_MAX_EXP	Maximal binary value of exponent degree for double type	Numerical Type Constants
DBL_MIN	Minimal positive value, which can be represented by double type	Numerical Type Constants
DBL_MIN_10_EXP	Minimal decimal value of exponent degree for double type	Numerical Type Constants
DBL_MIN_EXP	Minimal binary value of exponent degree for double type	Numerical Type Constants
DEAL_COMMENT	Deal comment	HistoryDealGetString
DEAL_COMMISSION	Deal commission	HistoryDealGetDouble
DEAL_ENTRY	Deal entry - entry in, entry out, reverse	HistoryDealGetInteger
DEAL_ENTRY_IN	Entry in	HistoryDealGetInteger
DEAL_ENTRY_INOUT	Reverse	HistoryDealGetInteger
DEAL_ENTRY_OUT	Entry out	HistoryDealGetInteger
DEAL_MAGIC	Deal magic number (see ORDER_MAGIC)	HistoryDealGetInteger
DEAL_ORDER	Deal order number	HistoryDealGetInteger
DEAL_POSITION_ID	Identifier of a position , in the opening, modification or change of which this deal took	HistoryDealGetInteger

	part. Each position has a unique identifier that is assigned to all deals executed for the symbol during the entire lifetime of the position.	
DEAL_PRICE	Deal price	HistoryDealGetDouble
DEAL_PROFIT	Deal profit	HistoryDealGetDouble
DEAL_SWAP	Cumulative swap on close	HistoryDealGetDouble
DEAL_SYMBOL	Deal symbol	HistoryDealGetString
DEAL_TIME	Deal time	HistoryDealGetInteger
DEAL_TIME_MSC	The time of a deal execution in milliseconds since 01.01.1970	HistoryDealGetInteger
DEAL_TYPE	Deal type	HistoryDealGetInteger
DEAL_TYPE_BALANCE	Balance	HistoryDealGetInteger
DEAL_TYPE_BONUS	Bonus	HistoryDealGetInteger
DEAL_TYPE_BUY	Buy	HistoryDealGetInteger
DEAL_TYPE_BUY_CANCELED	Canceled buy deal. There can be a situation when a previously executed buy deal is canceled. In this case, the type of the previously executed deal (DEAL_TYPE_BUY) is changed to DEAL_TYPE_BUY_CANCELED, and its profit/loss is zeroized. Previously obtained profit/loss is charged/withdrawn using a separated balance operation	HistoryDealGetInteger
DEAL_TYPE_CHARGE	Additional charge	HistoryDealGetInteger
DEAL_TYPE_COMMISSION	Additional commission	HistoryDealGetInteger
DEAL_TYPE_COMMISSION_AGENT_DAILY	Daily agent commission	HistoryDealGetInteger
DEAL_TYPE_COMMISSION_AGENT_MONTHLY	Monthly agent commission	HistoryDealGetInteger
DEAL_TYPE_COMMISSION_DAILY	Daily commission	HistoryDealGetInteger
DEAL_TYPE_COMMISSION_MONTHLY	Monthly commission	HistoryDealGetInteger

DEAL_TYPE_CORRECTION	Correction	HistoryDealGetInteger
DEAL_TYPE_CREDIT	Credit	HistoryDealGetInteger
DEAL_TYPE_INTEREST	Interest rate	HistoryDealGetInteger
DEAL_TYPE_SELL	Sell	HistoryDealGetInteger
DEAL_TYPE_SELL_CANCELED	Canceled sell deal. There can be a situation when a previously executed sell deal is canceled. In this case, the type of the previously executed deal (DEAL_TYPE_SELL) is changed to DEAL_TYPE_SELL_CANCELED, and its profit/loss is zeroized. Previously obtained profit/loss is charged/withdrawn using a separated balance operation	HistoryDealGetInteger
DEAL_VOLUME	Deal volume	HistoryDealGetDouble
DRAW_ARROW	Drawing arrows	Drawing Styles
DRAW_BARS	Display as a sequence of bars	Drawing Styles
DRAW_CANDLES	Display as a sequence of candlesticks	Drawing Styles
DRAW_COLOR_ARROW	Drawing multicolored arrows	Drawing Styles
DRAW_COLOR_BARS	Multicolored bars	Drawing Styles
DRAW_COLOR_CANDLES	Multicolored candlesticks	Drawing Styles
DRAW_COLOR_HISTOGRAM	Multicolored histogram from the zero line	Drawing Styles
DRAW_COLOR_HISTOGRAM2	Multicolored histogram of the two indicator buffers	Drawing Styles
DRAW_COLOR_LINE	Multicolored line	Drawing Styles
DRAW_COLOR_SECTION	Multicolored section	Drawing Styles
DRAW_COLOR_ZIGZAG	Multicolored ZigZag	Drawing Styles
DRAW_FILLING	Color fill between the two levels	Drawing Styles
DRAW_HISTOGRAM	Histogram from the zero line	Drawing Styles
DRAW_HISTOGRAM2	Histogram of the two indicator buffers	Drawing Styles
DRAW_LINE	Line	Drawing Styles

<u>DRAW_NONE</u>	Not drawn	<u>Drawing Styles</u>
<u>DRAW_SECTION</u>	Section	<u>Drawing Styles</u>
<u>DRAW_ZIGZAG</u>	Style Zigzag allows vertical section on the bar	<u>Drawing Styles</u>
ELLIOTT_CYCLE	Cycle	<u>ObjectSetInteger</u> , <u>ObjectGetInteger</u>
ELLIOTT_GRAND_SUPERCYCLE	Grand Supercycle	<u>ObjectSetInteger</u> , <u>ObjectGetInteger</u>
ELLIOTT_INTERMEDIATE	Intermediate	<u>ObjectSetInteger</u> , <u>ObjectGetInteger</u>
ELLIOTT_MINOR	Minor	<u>ObjectSetInteger</u> , <u>ObjectGetInteger</u>
ELLIOTT_MINUETTE	Minuette	<u>ObjectSetInteger</u> , <u>ObjectGetInteger</u>
ELLIOTT_MINUTE	Minute	<u>ObjectSetInteger</u> , <u>ObjectGetInteger</u>
ELLIOTT_PRIMARY	Primary	<u>ObjectSetInteger</u> , <u>ObjectGetInteger</u>
ELLIOTT_SUBMINUETTE	Subminuette	<u>ObjectSetInteger</u> , <u>ObjectGetInteger</u>
ELLIOTT_SUPERCYCLE	Supercycle	<u>ObjectSetInteger</u> , <u>ObjectGetInteger</u>
EMPTY_VALUE	Empty value in an indicator buffer	<u>Other Constants</u>
ERR_ACCOUNT_WRONG_PROPERTY	Wrong account property ID	<u>GetLastError</u>
ERR_ARRAY_BAD_SIZE	Requested array size exceeds 2 GB	<u>GetLastError</u>
ERR_ARRAY_RESIZE_ERROR	Not enough memory for the relocation of an array, or an attempt to change the size of a static array	<u>GetLastError</u>
ERR_BOOKS_CANNOT_ADD	Depth Of Market can not be added	<u>GetLastError</u>
ERR_BOOKS_CANNOT_DELETE	Depth Of Market can not be removed	<u>GetLastError</u>
ERR_BOOKS_CANNOT_GET	The data from Depth Of Market can not be obtained	<u>GetLastError</u>

ERR_BOOKS_CANNOT_SUBSCRIBE	Error in subscribing to receive new data from Depth Of Market	GetLastError
ERR_BUFFERS_NO_MEMORY	Not enough memory for the distribution of indicator buffers	GetLastError
ERR_BUFFERS_WRONG_INDEX	Wrong indicator buffer index	GetLastError
ERR_CANNOT_CLEAN_DIRECTORY	Failed to clear the directory (probably one or more files are blocked and removal operation failed)	GetLastError
ERR_CANNOT_DELETE_DIRECTORY	The directory cannot be removed	GetLastError
ERR_CANNOT_DELETE_FILE	File deleting error	GetLastError
ERR_CANNOT_OPEN_FILE	File opening error	GetLastError
ERR_CHAR_ARRAY_ONLY	Must be an array of type char	GetLastError
ERR_CHART_CANNOT_CHANGE	Failed to change chart symbol and period	GetLastError
ERR_CHART_CANNOT_CREATE_TIMER	Failed to create timer	GetLastError
ERR_CHART_CANNOT_OPEN	Chart opening error	GetLastError
ERR_CHART_INDICATOR_CANNOT_ADD	Error adding an indicator to chart	GetLastError
ERR_CHART_INDICATOR_CANNOT_DELETE	Error deleting an indicator from the chart	GetLastError
ERR_CHART_INDICATOR_NOT_FOUND	Indicator not found on the specified chart	GetLastError
ERR_CHART_NAVIGATE_FAILED	Error navigating through chart	GetLastError
ERR_CHART_NO_EXPERT	No Expert Advisor in the chart that could handle the event	GetLastError
ERR_CHART_NO_REPLY	Chart does not respond	GetLastError
ERR_CHART_NOT_FOUND	Chart not found	GetLastError
ERR_CHART_SCREENSHOT_FAILED	Error creating screenshots	GetLastError
ERR_CHART_TEMPLATE_FAILED	Error applying template	GetLastError

ERR_CHART_WINDOW_NOT_FOUND	Subwindow containing the indicator was not found	GetLastError
ERR_CHART_WRONG_ID	Wrong chart ID	GetLastError
ERR_CHART_WRONG_PARAMETER	Error value of the parameter for the function of working with charts	GetLastError
ERR_CHART_WRONG_PROPERTY	Wrong chart property ID	GetLastError
ERR_CUSTOM_WRONG_PROPERTY	Wrong ID of the custom indicator property	GetLastError
ERR_DIRECTORY_NOT_EXIST	Directory does not exist	GetLastError
ERR_DOUBLE_ARRAY_ONLY	Must be an array of type double	GetLastError
ERR_FILE_BINSTRINGSIZE	String size must be specified, because the file is opened as binary	GetLastError
ERR_FILE_CACHEBUFFER_ERROR	Not enough memory for cache to read	GetLastError
ERR_FILE_CANNOT_REWRITE	File can not be rewritten	GetLastError
ERR_FILE_IS_DIRECTORY	This is not a file, this is a directory	GetLastError
ERR_FILE_ISNOT_DIRECTORY	This is a file, not a directory	GetLastError
ERR_FILE_NOT_EXIST	File does not exist	GetLastError
ERR_FILE_NOTBIN	The file must be opened as a binary one	GetLastError
ERR_FILE_NOTCSV	The file must be opened as CSV	GetLastError
ERR_FILE_NOTTOREAD	The file must be opened for reading	GetLastError
ERR_FILE_NOTTOWRITE	The file must be opened for writing	GetLastError
ERR_FILE_NOTTXT	The file must be opened as a text	GetLastError
ERR_FILE_NOTTXTORCSV	The file must be opened as a text or CSV	GetLastError
ERR_FILE_READERROR	File reading error	GetLastError
ERR_FILE_WRITEERROR	Failed to write a resource to a file	GetLastError

ERR_FLOAT_ARRAY_ONLY	Must be an array of type float	GetLastError
ERR_FTP_SEND_FAILED	File sending via ftp failed	GetLastError
ERR_FUNCTION_NOT_ALLOWED	Function is not allowed for call	GetLastError
ERR_GLOBALVARIABLE_EXISTS	Global variable of the client terminal with the same name already exists	GetLastError
ERR_GLOBALVARIABLE_NOT_FOUND	Global variable of the client terminal is not found	GetLastError
ERR_HISTORY_NOT_FOUND	Requested history not found	GetLastError
ERR_HISTORY_WRONG_PROPERTY	Wrong ID of the history property	GetLastError
ERR_INCOMPATIBLE_ARRAYS	Copying incompatible arrays. String array can be copied only to a string array, and a numeric array - in numeric array only	GetLastError
ERR_INCOMPATIBLE_FILE	A text file must be for string arrays, for other arrays - binary	GetLastError
ERR_INDICATOR_CANNOT_ADD	Error applying an indicator to chart	GetLastError
ERR_INDICATOR_CANNOT_APPLY	The indicator cannot be applied to another indicator	GetLastError
ERR_INDICATOR_CANNOT_CREATE	Indicator cannot be created	GetLastError
ERR_INDICATOR_CUSTOM_NAME	The first parameter in the array must be the name of the custom indicator	GetLastError
ERR_INDICATOR_DATA_NOT_FOUND	Requested data not found	GetLastError
ERR_INDICATOR_NO_MEMORY	Not enough memory to add the indicator	GetLastError
ERR_INDICATOR_PARAMETER_TYPE	Invalid parameter type in the array when creating an indicator	GetLastError
ERR_INDICATOR_PARAMETERS_MISSING	No parameters when creating an indicator	GetLastError
ERR_INDICATOR_UNKNOWN_SYMBOL	Unknown symbol	GetLastError

ERR_INDICATOR_WRONG_HANDLE	Wrong indicator handle	GetLastError
ERR_INDICATOR_WRONG_INDEX	Wrong index of the requested indicator buffer	GetLastError
ERR_INDICATOR_WRONG_PARAMETERS	Wrong number of parameters when creating an indicator	GetLastError
ERR_INT_ARRAY_ONLY	Must be an array of type int	GetLastError
ERR_INTERNAL_ERROR	Unexpected internal error	GetLastError
ERR_INVALID_ARRAY	Array of a wrong type, wrong size, or a damaged object of a dynamic array	GetLastError
ERR_INVALID_DATETIME	Invalid date and/or time	GetLastError
ERR_INVALID_FILEHANDLE	A file with this handle was closed, or was not opening at all	GetLastError
ERR_INVALID_PARAMETER	Wrong parameter when calling the system function	GetLastError
ERR_INVALID_POINTER	Wrong pointer	GetLastError
ERR_INVALID_POINTER_TYPE	Wrong type of pointer	GetLastError
ERR_LONG_ARRAY_ONLY	Must be an array of type long	GetLastError
ERR_MAIL_SEND_FAILED	Email sending failed	GetLastError
ERR_MARKET_LASTTIME_UNKNOWN	Time of the last tick is not known (no ticks)	GetLastError
ERR_MARKET_NOT_SELECTED	Symbol is not selected in MarketWatch	GetLastError
ERR_MARKET_SELECT_ERROR	Error adding or deleting a symbol in MarketWatch	GetLastError
ERR_MARKET_UNKNOWN_SYMBOL	Unknown symbol	GetLastError
ERR_MARKET_WRONG_PROPERTY	Wrong identifier of a symbol property	GetLastError
ERR_MQL5_WRONG_PROPERTY	Wrong identifier of the program property	GetLastError
ERR_NO_STRING_DATE	No date in the string	GetLastError
ERR_NOT_ENOUGH_MEMORY	Not enough memory to perform the system function	GetLastError

ERR_NOTIFICATION_SEND_FAILED	Failed to send a notification	GetLastError
ERR_NOTIFICATION_TOO_FREQUENT	Too frequent sending of notifications	GetLastError
ERR_NOTIFICATION_WRONG_PARAMETER	Invalid parameter for sending a notification - an empty string or NULL has been passed to the SendNotification() function	GetLastError
ERR_NOTIFICATION_WRONG_SETTINGS	Wrong settings of notifications in the terminal (ID is not specified or permission is not set)	GetLastError
ERR_NOTINITIALIZED_STRING	Not initialized string	GetLastError
ERR_NUMBER_ARRAYS_ONLY	Must be a numeric array	GetLastError
ERR_OBJECT_ERROR	Error working with a graphical object	GetLastError
ERR_OBJECT_GETDATE_FAILED	Unable to get date corresponding to the value	GetLastError
ERR_OBJECT_GETVALUE_FAILED	Unable to get value corresponding to the date	GetLastError
ERR_OBJECT_NOT_FOUND	Graphical object was not found	GetLastError
ERR_OBJECT_WRONG_PROPERTY	Wrong ID of a graphical object property	GetLastError
ERR_ONEDIM_ARRAYS_ONLY	Must be a one-dimensional array	GetLastError
ERR_OPENCL_BUFFER_CREATE	Failed to create an OpenCL buffer	GetLastError
ERR_OPENCL_CONTEXT_CREATE	Error creating the OpenCL context	GetLastError
ERR_OPENCL_EXECUTE	OpenCL program runtime error	GetLastError
ERR_OPENCL_INTERNAL	Internal error occurred when running OpenCL	GetLastError
ERR_OPENCL_INVALID_HANDLE	Invalid OpenCL handle	GetLastError
ERR_OPENCL_KERNEL_CREATE	Error creating an OpenCL kernel	GetLastError
ERR_OPENCL_NOT_SUPPORTED	OpenCL functions are not supported on this computer	GetLastError

ERR_OPENCL_PROGRAM_CREATE	Error occurred when compiling an OpenCL program	GetLastError
ERR_OPENCL_QUEUE_CREATE	Failed to create a run queue in OpenCL	GetLastError
ERR_OPENCL_SET_KERNEL_PARAMETER	Error occurred when setting parameters for the OpenCL kernel	GetLastError
ERR_OPENCL_TOO_LONG_KERNEL_NAME	Too long kernel name (OpenCL kernel)	GetLastError
ERR_OPENCL_WRONG_BUFFER_OFFSET	Invalid offset in the OpenCL buffer	GetLastError
ERR_OPENCL_WRONG_BUFFER_SIZE	Invalid size of the OpenCL buffer	GetLastError
ERR_PLAY_SOUND_FAILED	Sound playing failed	GetLastError
ERR_RESOURCE_NAME_DUPLICATED	The names of the dynamic and the static resource match	GetLastError
ERR_RESOURCE_NAME_IS_TOO_LONG	The resource name exceeds 63 characters	GetLastError
ERR_RESOURCE_NOT_FOUND	Resource with this name has not been found in EX5	GetLastError
ERR_RESOURCE_UNSUPPORTED_TYPE	Unsupported resource type or its size exceeds 16 Mb	GetLastError
ERR_SERIES_ARRAY	Timeseries cannot be used	GetLastError
ERR_SHORT_ARRAY_ONLY	Must be an array of type short	GetLastError
ERR_SMALL_ARRAY	Too small array, the starting position is outside the array	GetLastError
ERR_SMALL_ASERIES_ARRAY	The receiving array is declared as AS_SERIES, and it is of insufficient size	GetLastError
ERR_STRING_OUT_OF_MEMORY	Not enough memory for the string	GetLastError
ERR_STRING_RESIZE_ERROR	Not enough memory for the relocation of string	GetLastError
ERR_STRING_SMALL_LEN	The string length is less than expected	GetLastError
ERR_STRING_TIME_ERROR	Error converting string to date	GetLastError
ERR_STRING_TOO_BIGNUMBER	Too large number, more than ULONG_MAX	GetLastError

ERR_STRING_UNKNOWNTYPE	Unknown data type when converting to a string	GetLastError
ERR_STRING_ZEROADDED	0 added to the string end, a useless operation	GetLastError
ERR_STRINGPOS_OUTOFRANGE	Position outside the string	GetLastError
ERR_STRUCT_WITHOBJECTS_ORCLASS	The structure contains objects of strings and/or dynamic arrays and/or structure of such objects and/or classes	GetLastError
ERR_SUCCESS	The operation completed successfully	GetLastError
ERR_TERMINAL_WRONG_PROPERTY	Wrong identifier of the terminal property	GetLastError
ERR_TOO_LONG_FILENAME	Too long file name	GetLastError
ERR_TOO_MANY_FILES	More than 64 files cannot be opened at the same time	GetLastError
ERR_TOO_MANY_FORMATTERS	Amount of format specifiers more than the parameters	GetLastError
ERR_TOO_MANY_PARAMETERS	Amount of parameters more than the format specifiers	GetLastError
ERR_TRADE_DEAL_NOT_FOUND	Deal not found	GetLastError
ERR_TRADE_DISABLED	Trading by Expert Advisors prohibited	GetLastError
ERR_TRADE_ORDER_NOT_FOUND	Order not found	GetLastError
ERR_TRADE_POSITION_NOT_FOUND	Position not found	GetLastError
ERR_TRADE_SEND_FAILED	Trade request sending failed	GetLastError
ERR_TRADE_WRONG_PROPERTY	Wrong trade property ID	GetLastError
ERR_USER_ERROR_FIRST	User defined errors start with this code	GetLastError
ERR_WEBREQUEST_CONNECT_FAILED	Failed to connect to specified URL	GetLastError
ERR_WEBREQUEST_INVALID_ADDRESS	Invalid URL	GetLastError

ERR_WEBREQUEST_REQUEST_FAILED	HTTP request failed	GetLastError
ERR_WEBREQUEST_TIMEOUT	Timeout exceeded	GetLastError
ERR_WRONG_DIRECTORYNAME	Wrong directory name	GetLastError
ERR_WRONG_FILEHANDLE	Wrong file handle	GetLastError
ERR_WRONG_FILENAME	Invalid file name	GetLastError
ERR_WRONG_FORMATSTRING	Invalid format string	GetLastError
ERR_WRONG_INTERNAL_PARAMETER	Wrong parameter in the inner call of the client terminal function	GetLastError
ERR_WRONG_STRING_DATE	Wrong date in the string	GetLastError
ERR_WRONG_STRING_OBJECT	Damaged string object	GetLastError
ERR_WRONG_STRING_PARAMETER	Damaged parameter of string type	GetLastError
ERR_WRONG_STRING_TIME	Wrong time in the string	GetLastError
ERR_ZEROSIZE_ARRAY	An array of zero length	GetLastError
FILE_ACCESS_DATE	Date of the last access to the file	FileGetInteger
FILE_ANSI	Strings of ANSI type (one byte symbols). Flag is used in FileOpen() .	FileOpen
FILE_BIN	Binary read/write mode (without string to string conversion). Flag is used in FileOpen() .	FileOpen
FILE_COMMON	The file path in the common folder of all client terminals \Terminal\Common\Files. Flag is used in FileOpen() , FileCopy() , FileMove() and in FileExists() functions.	FileOpen , FileCopy , FileMove , FileExists
FILE_CREATE_DATE	Date of creation	FileGetInteger
FILE_CSV	CSV file (all its elements are converted to strings of the appropriate type, Unicode or ANSI, and separated by separator). Flag is used in FileOpen() .	FileOpen

FILE_END	Get the end of file sign	FileGetInteger
FILE_EXISTS	Check the existence	FileGetInteger
FILE_IS_ANSI	The file is opened as ANSI (see FILE_ANSI)	FileGetInteger
FILE_IS_BINARY	The file is opened as a binary file (see FILE_BIN)	FileGetInteger
FILE_IS_COMMON	The file is opened in a shared folder of all terminals (see FILE_COMMON)	FileGetInteger
FILE_IS_CSV	The file is opened as CSV (see FILE_CSV)	FileGetInteger
FILE_IS_READABLE	The opened file is readable (see FILE_READ)	FileGetInteger
FILE_IS_TEXT	The file is opened as a text file (see FILE_TXT)	FileGetInteger
FILE_IS_WRITABLE	The opened file is writable (see FILE_WRITE)	FileGetInteger
FILE_LINE_END	Get the end of line sign	FileGetInteger
FILE_MODIFY_DATE	Date of the last modification	FileGetInteger
FILE_POSITION	Position of a pointer in the file	FileGetInteger
FILE_READ	File is opened for reading. Flag is used in FileOpen() . When opening a file specification of FILE_WRITE and/or FILE_READ is required.	FileOpen
FILE_REWRITE	Possibility for the file rewrite using functions FileCopy() and FileMove() . The file should exist or should be opened for writing, otherwise the file will not be opened.	FileCopy , FileMove
FILE_SHARE_READ	Shared access for reading from several programs. Flag is used in FileOpen() , but it does not replace the necessity to indicate FILE_WRITE and/or the FILE_READ flag when opening a file.	FileOpen
FILE_SHARE_WRITE	Shared access for writing from several programs. Flag is used in FileOpen() , but it does not	FileOpen

	replace the necessity to indicate FILE_WRITE and/or the FILE_READ flag when opening a file.	
FILE_SIZE	File size in bytes	FileGetInteger
FILE_TXT	Simple text file (the same as csv file, but without taking into account the separators). Flag is used in FileOpen() .	FileOpen
FILE_UNICODE	Strings of UNICODE type (two byte symbols). Flag is used in FileOpen() .	FileOpen
FILE_WRITE	File is opened for writing. Flag is used in FileOpen() . When opening a file specification of FILE_WRITE and/or FILE_READ is required.	FileOpen
FLT_DIG	Number of significant decimal digits for float type	Numerical Type Constants
FLT_EPSILON	Minimal value, which satisfies the condition: $1.0 + \text{DBL_EPSILON} \neq 1.0$ (for float type)	Numerical Type Constants
FLT_MANT_DIG	Bits count in a mantissa for float type	Numerical Type Constants
FLT_MAX	Maximal value, which can be represented by float type	Numerical Type Constants
FLT_MAX_10_EXP	Maximal decimal value of exponent degree for float type	Numerical Type Constants
FLT_MAX_EXP	Maximal binary value of exponent degree for float type	Numerical Type Constants
FLT_MIN	Minimal positive value, which can be represented by float type	Numerical Type Constants
FLT_MIN_10_EXP	Minimal decimal value of exponent degree for float type	Numerical Type Constants
FLT_MIN_EXP	Minimal binary value of exponent degree for float type	Numerical Type Constants

<u>OBJ_NO_PERIODS</u>	The object is not drawn in all timeframes	<u>ObjectSetInteger</u> , <u>ObjectGetInteger</u>
<u>OBJ_PERIOD_D1</u>	The object is drawn in day charts	<u>ObjectSetInteger</u> , <u>ObjectGetInteger</u>
<u>OBJ_PERIOD_H1</u>	The object is drawn in 1-hour chart	<u>ObjectSetInteger</u> , <u>ObjectGetInteger</u>
<u>OBJ_PERIOD_H12</u>	The object is drawn in 12-hour chart	<u>ObjectSetInteger</u> , <u>ObjectGetInteger</u>
<u>OBJ_PERIOD_H2</u>	The object is drawn in 2-hour chart	<u>ObjectSetInteger</u> , <u>ObjectGetInteger</u>

OBJ_PERIOD_H3	The object is drawn in 3-hour chart	ObjectSetInteger , ObjectGetInteger
OBJ_PERIOD_H4	The object is drawn in 4-hour chart	ObjectSetInteger , ObjectGetInteger
OBJ_PERIOD_H6	The object is drawn in 6-hour chart	ObjectSetInteger , ObjectGetInteger
OBJ_PERIOD_H8	The object is drawn in 8-hour chart	ObjectSetInteger , ObjectGetInteger
OBJ_PERIOD_M1	The object is drawn in 1-minute chart	ObjectSetInteger , ObjectGetInteger
OBJ_PERIOD_M10	The object is drawn in 10-minute chart	ObjectSetInteger , ObjectGetInteger
OBJ_PERIOD_M12	The object is drawn in 12-minute chart	ObjectSetInteger , ObjectGetInteger
OBJ_PERIOD_M15	The object is drawn in 15-minute chart	ObjectSetInteger , ObjectGetInteger
OBJ_PERIOD_M2	The object is drawn in 2-minute chart	ObjectSetInteger , ObjectGetInteger
OBJ_PERIOD_M20	The object is drawn in 20-minute chart	ObjectSetInteger , ObjectGetInteger
OBJ_PERIOD_M3	The object is drawn in 3-minute chart	ObjectSetInteger , ObjectGetInteger
OBJ_PERIOD_M30	The object is drawn in 30-minute chart	ObjectSetInteger , ObjectGetInteger
OBJ_PERIOD_M4	The object is drawn in 4-minute chart	ObjectSetInteger , ObjectGetInteger
OBJ_PERIOD_M5	The object is drawn in 5-minute chart	ObjectSetInteger , ObjectGetInteger
OBJ_PERIOD_M6	The object is drawn in 6-minute chart	ObjectSetInteger , ObjectGetInteger
OBJ_PERIOD_MN1	The object is drawn in month charts	ObjectSetInteger , ObjectGetInteger
OBJ_PERIOD_W1	The object is drawn in week charts	ObjectSetInteger , ObjectGetInteger
OBJ_PITCHFORK	Andrews' Pitchfork	Object Types
OBJ_RECTANGLE	Rectangle	Object Types
OBJ_RECTANGLE_LABEL	The "Rectangle label" object for creating and designing the custom graphical interface.	Object Types

<u>OBJ_REGRESSION</u>	Linear Regression Channel	<u>Object Types</u>
<u>OBJ_STDDEVCHANNEL</u>	Standard Deviation Channel	<u>Object Types</u>
<u>OBJ_TEXT</u>	Text	<u>Object Types</u>
<u>OBJ_TREND</u>	Trend Line	<u>Object Types</u>
<u>OBJ_TRENDBYANGLE</u>	Trend Line By Angle	<u>Object Types</u>
<u>OBJ_TRIANGLE</u>	Triangle	<u>Object Types</u>
<u>OBJ_VLINE</u>	Vertical Line	<u>Object Types</u>
OBJPROP_ALIGN	Horizontal text alignment in the "Edit" object (OBJ_EDIT)	<u>ObjectSetInteger</u> , <u>ObjectGetInteger</u>
OBJPROP_ANCHOR	Location of the anchor point of a graphical object	<u>ObjectSetInteger</u> , <u>ObjectGetInteger</u>
OBJPROP_ANGLE	Angle. For the objects with no angle specified, created from a program, the value is equal to <u>EMPTY_VALUE</u>	<u>ObjectSetDouble</u> , <u>ObjectGetDouble</u>
OBJPROP_ARROWCODE	Arrow code for the Arrow object	<u>ObjectSetInteger</u> , <u>ObjectGetInteger</u>
OBJPROP_BACK	Object in the background	<u>ObjectSetInteger</u> , <u>ObjectGetInteger</u>
OBJPROP_BGCOLOR	The background color for OBJ_EDIT, OBJ_BUTTON, OBJ_RECTANGLE_LABEL	<u>ObjectSetInteger</u> , <u>ObjectGetInteger</u>
OBJPROP_BMPFILE	The name of BMP-file for Bitmap Label. See also <u>Resources</u>	<u>ObjectSetString</u> , <u>ObjectGetString</u>
OBJPROP_BORDER_COLOR	Border color for the OBJ_EDIT and OBJ_BUTTON objects	<u>ObjectSetInteger</u> , <u>ObjectGetInteger</u>
OBJPROP_BORDER_TYPE	Border type for the "Rectangle label" object	<u>ObjectSetInteger</u> , <u>ObjectGetInteger</u>
OBJPROP_CHART_ID	ID of the "Chart" object (<u>OBJ_CHART</u>). It allows working with the properties of this object like with a normal chart using the functions described in <u>Chart Operations</u> , but there some <u>exceptions</u> .	<u>ObjectSetInteger</u> , <u>ObjectGetInteger</u>
OBJPROP_CHART_SCALE	The scale for the Chart object	<u>ObjectSetInteger</u> , <u>ObjectGetInteger</u>

OBJPROP_COLOR	Color	ObjectSetInteger , ObjectGetInteger
OBJPROP_CORNER	The corner of the chart to link a graphical object	ObjectSetInteger , ObjectGetInteger
OBJPROP_CREATETIME	Time of object creation	ObjectSetInteger , ObjectGetInteger
OBJPROP_DATE_SCALE	Displaying the time scale for the Chart object	ObjectSetInteger , ObjectGetInteger
OBJPROP_DEGREE	Level of the Elliott Wave Marking	ObjectSetInteger , ObjectGetInteger
OBJPROP_DEVIATION	Deviation for the Standard Deviation Channel	ObjectSetDouble , ObjectGetDouble
OBJPROP_DIRECTION	Trend of the Gann object	ObjectSetInteger , ObjectGetInteger
OBJPROP_DRAWLINES	Displaying lines for marking the Elliott Wave	ObjectSetInteger , ObjectGetInteger
OBJPROP_ELLIPSE	Showing the full ellipse of the Fibonacci Arc object (OBJ_FIBOARC)	ObjectSetInteger , ObjectGetInteger
OBJPROP_FILL	Fill an object with color (for OBJ_RECTANGLE , OBJ_TRIANGLE , OBJ_ELLIPSE , OBJ_CHANNEL , OBJ_STDDEVCHANNEL , OBJ_REGRESSION)	ObjectSetInteger , ObjectGetInteger
OBJPROP_FONT	Font	ObjectSetString , ObjectGetString
OBJPROP_FONTSIZE	Font size	ObjectSetInteger , ObjectGetInteger
OBJPROP_HIDDEN	Prohibit showing of the name of a graphical object in the list of objects from the terminal menu "Charts" - "Objects" - "List of objects". The true value allows to hide an object from the list. By default, true is set to the objects that display calendar events, trading history and to the objects created from MQL5 programs . To see such graphical objects and access their properties, click on the	ObjectSetInteger , ObjectGetInteger

	"All" button in the "List of objects" window.	
OBJPROP_LEVELCOLOR	Color of the line-level	ObjectSetInteger , ObjectGetInteger
OBJPROP_LEVELS	Number of levels	ObjectSetInteger , ObjectGetInteger
OBJPROP_LEVELSTYLE	Style of the line-level	ObjectSetInteger , ObjectGetInteger
OBJPROP_LEVELTEXT	Level description	ObjectSetString , ObjectGetString
OBJPROP_LEVELVALUE	Level value	ObjectSetDouble , ObjectGetDouble
OBJPROP_LEVELWIDTH	Thickness of the line-level	ObjectSetInteger , ObjectGetInteger
OBJPROP_NAME	Object name	ObjectSetString , ObjectGetString
OBJPROP_PERIOD	Timeframe for the Chart object	ObjectSetInteger , ObjectGetInteger
OBJPROP_PRICE	Price coordinate	ObjectSetDouble , ObjectGetDouble
OBJPROP_PRICE_SCALE	Displaying the price scale for the Chart object	ObjectSetInteger , ObjectGetInteger
OBJPROP_RAY	A vertical line goes through all the windows of a chart	ObjectSetInteger , ObjectGetInteger
OBJPROP_RAY_LEFT	Ray goes to the left	ObjectSetInteger , ObjectGetInteger
OBJPROP_RAY_RIGHT	Ray goes to the right	ObjectSetInteger , ObjectGetInteger
OBJPROP_READONLY	Ability to edit text in the Edit object	ObjectSetInteger , ObjectGetInteger
OBJPROP_SCALE	Scale (properties of Gann objects and Fibonacci Arcs)	ObjectSetDouble , ObjectGetDouble
OBJPROP_SELECTABLE	Object availability	ObjectSetInteger , ObjectGetInteger
OBJPROP_SELECTED	Object is selected	ObjectSetInteger , ObjectGetInteger
OBJPROP_STATE	Button state (pressed / depressed)	ObjectSetInteger , ObjectGetInteger

OBJPROP_STYLE	Style	ObjectSetInteger , ObjectGetInteger
OBJPROP_SYMBOL	Symbol for the Chart object	ObjectSetString , ObjectGetString
OBJPROP_TEXT	Description of the object (the text contained in the object)	ObjectSetString , ObjectGetString
OBJPROP_TIME	Time coordinate	ObjectSetInteger , ObjectGetInteger
OBJPROP_TIMEFRAMES	Visibility of an object at timeframes	ObjectSetInteger , ObjectGetInteger
OBJPROP_TOOLTIP	The text of a tooltip. If the property is not set, then the tooltip generated automatically by the terminal is shown. A tooltip can be disabled by setting the "\n" (line feed) value to it	ObjectSetString , ObjectGetString
OBJPROP_TYPE	Object type	ObjectSetInteger , ObjectGetInteger
OBJPROP_WIDTH	Line thickness	ObjectSetInteger , ObjectGetInteger
OBJPROP_XDISTANCE	The distance in pixels along the X axis from the binding corner (see note)	ObjectSetInteger , ObjectGetInteger
OBJPROP_XOFFSET	The X coordinate of the upper left corner of the rectangular visible area in the graphical objects "Bitmap Label" and "Bitmap" (OBJ_BITMAP_LABEL and OBJ_BITMAP). The value is set in pixels relative to the upper left corner of the original image.	ObjectSetInteger , ObjectGetInteger
OBJPROP_XSIZE	The object's width along the X axis in pixels. Specified for OBJ_LABEL (read only), OBJ_BUTTON, OBJ_CHART, OBJ_BITMAP, OBJ_BITMAP_LABEL, OBJ_EDIT, OBJ_RECTANGLE_LABEL objects.	ObjectSetInteger , ObjectGetInteger

OBJPROP_YDISTANCE	The distance in pixels along the Y axis from the binding corner (see note)	ObjectSetInteger , ObjectGetInteger
OBJPROP_YOFFSET	The Y coordinate of the upper left corner of the rectangular visible area in the graphical objects "Bitmap Label" and "Bitmap" (OBJ_BITMAP_LABEL and OBJ_BITMAP). The value is set in pixels relative to the upper left corner of the original image.	ObjectSetInteger , ObjectGetInteger
OBJPROP_YSIZE	The object's height along the Y axis in pixels. Specified for OBJ_LABEL (read only), OBJ_BUTTON, OBJ_CHART, OBJ_BITMAP, OBJ_BITMAP_LABEL, OBJ_EDIT, OBJ_RECTANGLE_LABEL objects.	ObjectSetInteger , ObjectGetInteger
OBJPROP_ZORDER	Priority of a graphical object for receiving events of clicking on a chart (CHARTEVENT_CLICK). The default zero value is set when creating an object; the priority can be increased if necessary. When applying objects one over another, only one of them with the highest priority will receive the CHARTEVENT_CLICK event.	ObjectSetInteger , ObjectGetInteger
ORDER_COMMENT	Order comment	OrderGetString , HistoryOrderGetString
ORDER_FILLING_FOK	This filling policy means that an order can be filled only in the specified amount. If the necessary amount of a financial instrument is currently unavailable in the market, the order will not be executed. The required volume can be filled using several offers available on the market at the moment.	OrderGetInteger , HistoryOrderGetInteger

ORDER_FILLING_IOC	This mode means that a trader agrees to execute a deal with the volume maximally available in the market within that indicated in the order. In case the the entire volume of an order cannot be filled, the available volume of it will be filled, and the remaining volume will be canceled.	OrderGetInteger , HistoryOrderGetInteger
ORDER_FILLING_RETURN	This policy is used only for market orders (ORDER_TYPE_BUY and ORDER_TYPE_SELL), limit and stop limit orders (ORDER_TYPE_BUY_LIMIT, ORDER_TYPE_SELL_LIMIT, ORDER_TYPE_BUY_STOP_LIMIT and ORDER_TYPE_SELL_STOP_LIMIT) and only for the symbols with Market or Exchange execution . In case of partial filling a market or limit order with remaining volume is not canceled but processed further. For the activation of the ORDER_TYPE_BUY_STOP_LIMIT and ORDER_TYPE_SELL_STOP_LIMIT orders, a corresponding limit order ORDER_TYPE_BUY_LIMIT/ORDER_TYPE_SELL_LIMIT with the ORDER_FILLING_RETURN execution type is created.	OrderGetInteger , HistoryOrderGetInteger
ORDER_MAGIC	ID of an Expert Advisor that has placed the order (designed to ensure that each Expert Advisor places its own unique number)	OrderGetInteger , HistoryOrderGetInteger
ORDER_POSITION_ID	Position identifier that is set to an order as soon as it is executed. Each executed order results in a deal that opens or modifies an already existing position. The identifier of	OrderGetInteger , HistoryOrderGetInteger

	exactly this position is set to the executed order at this moment.	
ORDER_PRICE_CURRENT	The current price of the order symbol	OrderGetDouble , HistoryOrderGetDouble
ORDER_PRICE_OPEN	Price specified in the order	OrderGetDouble , HistoryOrderGetDouble
ORDER_PRICE_STOPLIMIT	The Limit order price for the StopLimit order	OrderGetDouble , HistoryOrderGetDouble
ORDER_SL	Stop Loss value	OrderGetDouble , HistoryOrderGetDouble
ORDER_STATE	Order state	OrderGetInteger , HistoryOrderGetInteger
ORDER_STATE_CANCELED	Order canceled by client	OrderGetInteger , HistoryOrderGetInteger
ORDER_STATE_EXPIRED	Order expired	OrderGetInteger , HistoryOrderGetInteger
ORDER_STATE_FILLED	Order fully executed	OrderGetInteger , HistoryOrderGetInteger
ORDER_STATE_PARTIAL	Order partially executed	OrderGetInteger , HistoryOrderGetInteger
ORDER_STATE_PLACED	Order accepted	OrderGetInteger , HistoryOrderGetInteger
ORDER_STATE_REJECTED	Order rejected	OrderGetInteger , HistoryOrderGetInteger
ORDER_STATE_REQUEST_ADD	Order is being registered (placing to the trading system)	OrderGetInteger , HistoryOrderGetInteger
ORDER_STATE_REQUEST_CANCEL	Order is being deleted (deleting from the trading system)	OrderGetInteger , HistoryOrderGetInteger
ORDER_STATE_REQUEST_MODIFY	Order is being modified (changing its parameters)	OrderGetInteger , HistoryOrderGetInteger
ORDER_STATE_STARTED	Order checked, but not yet accepted by broker	OrderGetInteger , HistoryOrderGetInteger
ORDER_SYMBOL	Symbol of the order	OrderGetString , HistoryOrderGetString
ORDER_TIME_DAY	Good till current trade day order	OrderGetInteger , HistoryOrderGetInteger

ORDER_TIME_DONE	Order execution or cancellation time	OrderGetInteger , HistoryOrderGetInteger
ORDER_TIME_DONE_MSC	Order execution/cancellation time in milliseconds since 01.01.1970	OrderGetInteger , HistoryOrderGetInteger
ORDER_TIME_EXPIRATION	Order expiration time	OrderGetInteger , HistoryOrderGetInteger
ORDER_TIME_GTC	Good till cancel order	OrderGetInteger , HistoryOrderGetInteger
ORDER_TIME_SETUP	Order setup time	OrderGetInteger , HistoryOrderGetInteger
ORDER_TIME_SETUP_MSC	The time of placing an order for execution in milliseconds since 01.01.1970	OrderGetInteger , HistoryOrderGetInteger
ORDER_TIME_SPECIFIED	Good till expired order	OrderGetInteger , HistoryOrderGetInteger
ORDER_TIME_SPECIFIED_DAY	The order will be effective till 23:59:59 of the specified day. If this time is outside a trading session, the order expires in the nearest trading time.	OrderGetInteger , HistoryOrderGetInteger
ORDER_TP	Take Profit value	OrderGetDouble , HistoryOrderGetDouble
ORDER_TYPE	Order type	OrderGetInteger , HistoryOrderGetInteger
ORDER_TYPE_BUY	Market Buy order	OrderGetInteger , HistoryOrderGetInteger
ORDER_TYPE_BUY_LIMIT	Buy Limit pending order	OrderGetInteger , HistoryOrderGetInteger
ORDER_TYPE_BUY_STOP	Buy Stop pending order	OrderGetInteger , HistoryOrderGetInteger
ORDER_TYPE_BUY_STOP_LIMIT	Upon reaching the order price, a pending Buy Limit order is placed at the StopLimit price	OrderGetInteger , HistoryOrderGetInteger
ORDER_TYPE_FILLING	Order filling type	OrderGetInteger , HistoryOrderGetInteger
ORDER_TYPE_SELL	Market Sell order	OrderGetInteger , HistoryOrderGetInteger

ORDER_TYPE_SELL_LIMIT	Sell Limit pending order	OrderGetInteger , HistoryOrderGetInteger
ORDER_TYPE_SELL_STOP	Sell Stop pending order	OrderGetInteger , HistoryOrderGetInteger
ORDER_TYPE_SELL_STOP_LIMIT	Upon reaching the order price, a pending Sell Limit order is placed at the StopLimit price	OrderGetInteger , HistoryOrderGetInteger
ORDER_TYPE_TIME	Order lifetime	OrderGetInteger , HistoryOrderGetInteger
ORDER_VOLUME_CURRENT	Order current volume	OrderGetDouble , HistoryOrderGetDouble
ORDER_VOLUME_INITIAL	Order initial volume	OrderGetDouble , HistoryOrderGetDouble
PERIOD_CURRENT	Current timeframe	Chart Timeframes
PERIOD_D1	1 day	Chart Timeframes
PERIOD_H1	1 hour	Chart Timeframes
PERIOD_H12	12 hours	Chart Timeframes
PERIOD_H2	2 hours	Chart Timeframes
PERIOD_H3	3 hours	Chart Timeframes
PERIOD_H4	4 hours	Chart Timeframes
PERIOD_H6	6 hours	Chart Timeframes
PERIOD_H8	8 hours	Chart Timeframes
PERIOD_M1	1 minute	Chart Timeframes
PERIOD_M10	10 minutes	Chart Timeframes
PERIOD_M12	12 minutes	Chart Timeframes
PERIOD_M15	15 minutes	Chart Timeframes
PERIOD_M2	2 minutes	Chart Timeframes
PERIOD_M20	20 minutes	Chart Timeframes
PERIOD_M3	3 minutes	Chart Timeframes
PERIOD_M30	30 minutes	Chart Timeframes
PERIOD_M4	4 minutes	Chart Timeframes
PERIOD_M5	5 minutes	Chart Timeframes
PERIOD_M6	6 minutes	Chart Timeframes
PERIOD_MN1	1 month	Chart Timeframes

PERIOD_W1	1 week	Chart Timeframes
PLOT_ARROW	Arrow code for style DRAW_ARROW	PlotIndexSetInteger , PlotIndexGetInteger
PLOT_ARROW_SHIFT	Vertical shift of arrows for style DRAW_ARROW	PlotIndexSetInteger , PlotIndexGetInteger
PLOT_COLOR_INDEXES	The number of colors	PlotIndexSetInteger , PlotIndexGetInteger
PLOT_DRAW_BEGIN	Number of initial bars without drawing and values in the DataWindow	PlotIndexSetInteger , PlotIndexGetInteger
PLOT_DRAW_TYPE	Type of graphical construction	PlotIndexSetInteger , PlotIndexGetInteger
PLOT_EMPTY_VALUE	An empty value for plotting, for which there is no drawing	PlotIndexSetDouble
PLOT_LABEL	The name of the indicator graphical series to display in the DataWindow. When working with complex graphical styles requiring several indicator buffers for display, the names for each buffer can be specified using ";" as a separator. Sample code is shown in DRAW_CANDLES	PlotIndexSetString
PLOT_LINE_COLOR	The index of a buffer containing the drawing color	PlotIndexSetInteger , PlotIndexGetInteger
PLOT_LINE_STYLE	Drawing line style	PlotIndexSetInteger , PlotIndexGetInteger
PLOT_LINE_WIDTH	The thickness of the drawing line	PlotIndexSetInteger , PlotIndexGetInteger
PLOT_SHIFT	Shift of indicator plotting along the time axis in bars	PlotIndexSetInteger , PlotIndexGetInteger
PLOT_SHOW_DATA	Sign of display of construction values in the DataWindow	PlotIndexSetInteger , PlotIndexGetInteger
PLUSDI_LINE	Line +DI	Indicators Lines
POINTER_AUTOMATIC	Pointer of any objects created automatically (not using new())	CheckPointer
POINTER_DYNAMIC	Pointer of the object created by the new() operator	CheckPointer

POINTER_INVALID	Incorrect pointer	CheckPointer
POSITION_COMMENT	Position comment	PositionGetString
POSITION_COMMISSION	Commission	PositionGetDouble
POSITION_IDENTIFIER	Position identifier is a unique number that is assigned to every newly opened position and doesn't change during the entire lifetime of the position. Position turnover doesn't change its identifier.	PositionGetInteger
POSITION_MAGIC	Position magic number (see ORDER_MAGIC)	PositionGetInteger
POSITION_PRICE_CURRENT	Current price of the position symbol	PositionGetDouble
POSITION_PRICE_OPEN	Position open price	PositionGetDouble
POSITION_PROFIT	Current profit	PositionGetDouble
POSITION_SL	Stop Loss level of opened position	PositionGetDouble
POSITION_SWAP	Cumulative swap	PositionGetDouble
POSITION_SYMBOL	Symbol of the position	PositionGetString
POSITION_TIME	Position open time	PositionGetInteger
POSITION_TIME_MSC	Position opening time in milliseconds since 01.01.1970	PositionGetInteger
POSITION_TIME_UPDATE	Position changing time in seconds since 01.01.1970	PositionGetInteger
POSITION_TIME_UPDATE_MSC	Position changing time in milliseconds since 01.01.1970	PositionGetInteger
POSITION_TP	Take Profit level of opened position	PositionGetDouble
POSITION_TYPE	Position type	PositionGetInteger
POSITION_TYPE_BUY	Buy	PositionGetInteger
POSITION_TYPE_SELL	Sell	PositionGetInteger
POSITION_VOLUME	Position volume	PositionGetDouble
PRICE_CLOSE	Close price	Price Constants
PRICE_HIGH	The maximum price for the period	Price Constants

PRICE_LOW	The minimum price for the period	Price Constants
PRICE_MEDIAN	Median price, (high + low)/2	Price Constants
PRICE_OPEN	Open price	Price Constants
PRICE_TYPICAL	Typical price, (high + low + close)/3	Price Constants
PRICE_WEIGHTED	Average price, (high + low + close + close)/4	Price Constants
PROGRAM_EXPERT	Expert	MQLInfoInteger
PROGRAM_INDICATOR	Indicator	MQLInfoInteger
PROGRAM_SCRIPT	Script	MQLInfoInteger
REASON_ACCOUNT	Another account has been activated or reconnection to the trade server has occurred due to changes in the account settings	UninitializeReason , OnDeinit
REASON_CHARTCHANGE	Symbol or chart period has been changed	UninitializeReason , OnDeinit
REASON_CHARTCLOSE	Chart has been closed	UninitializeReason , OnDeinit
REASON_CLOSE	Terminal has been closed	UninitializeReason , OnDeinit
REASON_INITFAILED	This value means that OnInit() handler has returned a nonzero value	UninitializeReason , OnDeinit
REASON_PARAMETERS	Input parameters have been changed by a user	UninitializeReason , OnDeinit
REASON_PROGRAM	Expert Advisor terminated its operation by calling the ExpertRemove() function	UninitializeReason , OnDeinit
REASON_RECOMPILE	Program has been recompiled	UninitializeReason , OnDeinit
REASON_REMOVE	Program has been deleted from the chart	UninitializeReason , OnDeinit
REASON_TEMPLATE	A new template has been applied	UninitializeReason , OnDeinit
SATURDAY	Saturday	SymbolInfoInteger , SymbolInfoSessionQuote , SymbolInfoSessionTrade
SEEK_CUR	Current position of a file pointer	FileSeek

SEEK_END	File end	FileSeek
SEEK_SET	File beginning	FileSeek
SENKOUSPANA_LINE	Senkou Span A line	Indicators Lines
SENKOUSPANB_LINE	Senkou Span B line	Indicators Lines
SERIES_BARS_COUNT	Bars count for the symbol-period for the current moment	SeriesInfoInteger
SERIES_FIRSTDATE	The very first date for the symbol-period for the current moment	SeriesInfoInteger
SERIES_LASTBAR_DATE	Open time of the last bar of the symbol-period	SeriesInfoInteger
SERIES_SERVER_FIRSTDATE	The very first date in the history of the symbol on the server regardless of the timeframe	SeriesInfoInteger
SERIES_SYNCHRONIZED	Symbol/period data synchronization flag for the current moment	SeriesInfoInteger
SERIES_TERMINAL_FIRSTDATE	The very first date in the history of the symbol in the client terminal, regardless of the timeframe	SeriesInfoInteger
SHORT_MAX	Maximal value, which can be represented by short type	Numerical Type Constants
SHORT_MIN	Minimal value, which can be represented by short type	Numerical Type Constants
SIGNAL_BASE_AUTHOR_LOGIN	Author login	SignalBaseGetString
SIGNAL_BASE_BALANCE	Account balance	SignalBaseGetDouble
SIGNAL_BASE_BROKER	Broker name (company)	SignalBaseGetString
SIGNAL_BASE_BROKER_SERVER	Broker server	SignalBaseGetString
SIGNAL_BASE_CURRENCY	Signal base currency	SignalBaseGetString
SIGNAL_BASE_DATE_PUBLISHED	Publication date (date when it become available for subscription)	SignalBaseGetInteger
SIGNAL_BASE_DATE_STARTED	Monitoring starting date	SignalBaseGetInteger
SIGNAL_BASE_EQUITY	Account equity	SignalBaseGetDouble
SIGNAL_BASE_GAIN	Account gain	SignalBaseGetDouble

SIGNAL_BASE_ID	Signal ID	SignalBaseGetInteger
SIGNAL_BASE_LEVERAGE	Account leverage	SignalBaseGetInteger
SIGNAL_BASE_MAX_DRAWDOWN	Account maximum drawdown	SignalBaseGetDouble
SIGNAL_BASE_NAME	Signal name	SignalBaseGetString
SIGNAL_BASE_PIPS	Profit in pips	SignalBaseGetInteger
SIGNAL_BASE_PRICE	Signal subscription price	SignalBaseGetDouble
SIGNAL_BASE_RATING	Position in rating	SignalBaseGetInteger
SIGNAL_BASE_ROI	Return on Investment (%)	SignalBaseGetDouble
SIGNAL_BASE_SUBSCRIBERS	Number of subscribers	SignalBaseGetInteger
SIGNAL_BASE_TRADE_MODE	Account type (0-real, 1-demo, 2-contest)	SignalBaseGetInteger
SIGNAL_BASE_TRADES	Number of trades	SignalBaseGetInteger
SIGNAL_INFO_CONFIRMATION_S_DISABLED	The flag enables synchronization without confirmation dialog	SignalInfoGetInteger , SignalInfoSetInteger
SIGNAL_INFO_COPY_SLTP	Copy Stop Loss and Take Profit flag	SignalInfoGetInteger , SignalInfoSetInteger
SIGNAL_INFO_DEPOSIT_PERCENT	Deposit percent (%)	SignalInfoGetInteger , SignalInfoSetInteger
SIGNAL_INFO_EQUITY_LIMIT	Equity limit	SignalInfoGetDouble , SignalInfoSetDouble
SIGNAL_INFO_ID	Signal id, r/o	SignalInfoGetInteger , SignalInfoSetInteger
SIGNAL_INFO_NAME	Signal name, r/o	SignalInfoGetString
SIGNAL_INFO_SLIPPAGE	Slippage (used when placing market orders in synchronization of positions and copying of trades)	SignalInfoGetDouble , SignalInfoSetDouble
SIGNAL_INFO_SUBSCRIPTION_ENABLED	"Copy trades by subscription" permission flag	SignalInfoGetInteger , SignalInfoSetInteger
SIGNAL_INFO_TERMS_AGREE	"Agree to terms of use of Signals service" flag, r/o	SignalInfoGetInteger , SignalInfoSetInteger
SIGNAL_INFO_VOLUME_PERCENT	Maximum percent of deposit used (%), r/o	SignalInfoGetDouble , SignalInfoSetDouble
SIGNAL_LINE	Signal line	Indicators Lines

STAT_BALANCE_DD	Maximum balance drawdown in monetary terms. In the process of trading, a balance may have numerous drawdowns; here the largest value is taken	TesterStatistics
STAT_BALANCE_DD_RELATIVE	Balance drawdown in monetary terms that was recorded at the moment of the maximum balance drawdown as a percentage (STAT_BALANCE_DDREL_PERCENT).	TesterStatistics
STAT_BALANCE_DDREL_PERCENT	Maximum balance drawdown as a percentage. In the process of trading, a balance may have numerous drawdowns, for each of which the relative drawdown value in percents is calculated. The greatest value is returned	TesterStatistics
STAT_BALANCEDD_PERCENT	Balance drawdown as a percentage that was recorded at the moment of the maximum balance drawdown in monetary terms (STAT_BALANCE_DD).	TesterStatistics
STAT_BALANCEMIN	Minimum balance value	TesterStatistics
STAT_CONLOSSMAX	Maximum loss in a series of losing trades. The value is less than or equal to zero	TesterStatistics
STAT_CONLOSSMAX_TRADES	The number of trades that have formed STAT_CONLOSSMAX (maximum loss in a series of losing trades)	TesterStatistics
STAT_CONPROFITMAX	Maximum profit in a series of profitable trades. The value is greater than or equal to zero	TesterStatistics
STAT_CONPROFITMAX_TRADES	The number of trades that have formed STAT_CONPROFITMAX (maximum profit in a series of profitable trades)	TesterStatistics

STAT_CUSTOM_ONTESTER	The value of the calculated custom optimization criterion returned by the OnTester() function	TesterStatistics
STAT_DEALS	The number of deals	TesterStatistics
STAT_EQUITY_DD	Maximum equity drawdown in monetary terms. In the process of trading, numerous drawdowns may appear on the equity; here the largest value is taken	TesterStatistics
STAT_EQUITY_DD_RELATIVE	Equity drawdown in monetary terms that was recorded at the moment of the maximum equity drawdown in percent (STAT_EQUITY_DDREL_PERCENT).	TesterStatistics
STAT_EQUITY_DDREL_PERCENT	Maximum equity drawdown as a percentage. In the process of trading, an equity may have numerous drawdowns, for each of which the relative drawdown value in percents is calculated. The greatest value is returned	TesterStatistics
STAT_EQUITYDD_PERCENT	Drawdown in percent that was recorded at the moment of the maximum equity drawdown in monetary terms (STAT_EQUITY_DD).	TesterStatistics
STAT_EQUITYMIN	Minimum equity value	TesterStatistics
STAT_EXPECTED_PAYOFF	Expected payoff	TesterStatistics
STAT_GROSS_LOSS	Total loss, the sum of all negative trades. The value is less than or equal to zero	TesterStatistics
STAT_GROSS_PROFIT	Total profit, the sum of all profitable (positive) trades. The value is greater than or equal to zero	TesterStatistics
STAT_INITIAL_DEPOSIT	The value of the initial deposit	TesterStatistics
STAT_LONG_TRADES	Long trades	TesterStatistics
STAT_LOSS_TRADES	Losing trades	TesterStatistics

STAT_LOSSTRADES_AVGCON	Average length of a losing series of trades	TesterStatistics
STAT_MAX_CONLOSS_TRADES	The number of trades in the longest series of losing trades STAT_MAX_CONLOSSES	TesterStatistics
STAT_MAX_CONLOSSES	The total loss of the longest series of losing trades	TesterStatistics
STAT_MAX_CONPROFIT_TRADES	The number of trades in the longest series of profitable trades STAT_MAX_CONWINS	TesterStatistics
STAT_MAX_CONWINS	The total profit of the longest series of profitable trades	TesterStatistics
STAT_MAX_LOSSTRADE	Maximum loss - the lowest value of all losing trades. The value is less than or equal to zero	TesterStatistics
STAT_MAX_PROFITTRADE	Maximum profit - the largest value of all profitable trades. The value is greater than or equal to zero	TesterStatistics
STAT_MIN_MARGINLEVEL	Minimum value of the margin level	TesterStatistics
STAT_PROFIT	Net profit after testing, the sum of STAT_GROSS_PROFIT and STAT_GROSS_LOSS (STAT_GROSS_LOSS is always less than or equal to zero)	TesterStatistics
STAT_PROFIT_FACTOR	Profit factor, equal to the ratio of STAT_GROSS_PROFIT/STAT_GROSS_LOSS. If STAT_GROSS_LOSS=0, the profit factor is equal to DBL_MAX	TesterStatistics
STAT_PROFIT_LONGTRADES	Profitable long trades	TesterStatistics
STAT_PROFIT_SHORTTRADES	Profitable short trades	TesterStatistics
STAT_PROFIT_TRADES	Profitable trades	TesterStatistics
STAT_PROFITTRADES_AVGCON	Average length of a profitable series of trades	TesterStatistics
STAT_RECOVERY_FACTOR	Recovery factor, equal to the ratio of	TesterStatistics

	STAT_PROFIT/STAT_BALANCE_DD	
STAT_SHARPE_RATIO	Sharpe ratio	TesterStatistics
STAT_SHORT_TRADES	Short trades	TesterStatistics
STAT_TRADES	The number of trades	TesterStatistics
STAT_WITHDRAWAL	Money withdrawn from an account	TesterStatistics
STO_CLOSECLOSE	Calculation is based on Close/Close prices	Price Constants
STO_LOWHIGH	Calculation is based on Low/High prices	Price Constants
STYLE_DASH	Broken line	Drawing Styles
STYLE_DASHDOT	Dash-dot line	Drawing Styles
STYLE_DASHDOTDOT	Dash - two points	Drawing Styles
STYLE_DOT	Dotted line	Drawing Styles
STYLE_SOLID	Solid line	Drawing Styles
SUNDAY	Sunday	SymbolInfoInteger , SymbolInfoSessionQuote , SymbolInfoSessionTrade
SYMBOL_ASK	Ask - best buy offer	SymbolInfoDouble
SYMBOL_ASKHIGH	Maximal Ask of the day	SymbolInfoDouble
SYMBOL_ASKLOW	Minimal Ask of the day	SymbolInfoDouble
SYMBOL_BANK	Feeder of the current quote	SymbolInfoString
SYMBOL_BASIS	The underlying asset of a derivative	SymbolInfoString
SYMBOL_BID	Bid - best sell offer	SymbolInfoDouble
SYMBOL_BIDHIGH	Maximal Bid of the day	SymbolInfoDouble
SYMBOL_BIDLOW	Minimal Bid of the day	SymbolInfoDouble
SYMBOL_CALC_MODE_CFD	CFD mode - calculation of margin and profit for CFD	SymbolInfoInteger
SYMBOL_CALC_MODE_CFDINDEX	CFD index mode - calculation of margin and profit for CFD by indexes	SymbolInfoInteger
SYMBOL_CALC_MODE_CFDLEVERAGE	CFD Leverage mode - calculation of margin and	SymbolInfoInteger

	profit for CFD at leverage trading	
SYMBOL_CALC_MODE_EXCH_FUTURES	Futures mode - calculation of margin and profit for trading futures contracts on a stock exchange	SymbolInfoInteger
SYMBOL_CALC_MODE_EXCH_FUTURES_FORTS	FORTS Futures mode - calculation of margin and profit for trading futures contracts on FORTS.	SymbolInfoInteger
SYMBOL_CALC_MODE_EXCH_STOCKS	Exchange mode - calculation of margin and profit for trading securities on a stock exchange	SymbolInfoInteger
SYMBOL_CALC_MODE_FOREX	Forex mode - calculation of profit and margin for Forex	SymbolInfoInteger
SYMBOL_CALC_MODE_FUTURES	Futures mode - calculation of margin and profit for futures	SymbolInfoInteger
SYMBOL_CALC_MODE_SERV_COLLATERAL	Collateral mode - a symbol is used as a non-tradable asset on a trading account.	SymbolInfoInteger
SYMBOL_CURRENCY_BASE	Basic currency of a symbol	SymbolInfoString
SYMBOL_CURRENCY_MARGIN	Margin currency	SymbolInfoString
SYMBOL_CURRENCY_PROFIT	Profit currency	SymbolInfoString
SYMBOL_DESCRIPTION	Symbol description	SymbolInfoString
SYMBOL_DIGITS	Digits after a decimal point	SymbolInfoInteger
SYMBOL_EXPIRATION_DAY	The order is valid till the end of the day	SymbolInfoInteger
SYMBOL_EXPIRATION_GTC	The order is valid during the unlimited time period, until it is explicitly canceled	SymbolInfoInteger
SYMBOL_EXPIRATION_MODE	Flags of allowed order expiration modes	SymbolInfoInteger
SYMBOL_EXPIRATION_SPECIFIED	The expiration time is specified in the order	SymbolInfoInteger
SYMBOL_EXPIRATION_SPECIFIED_DAY	The expiration date is specified in the order	SymbolInfoInteger
SYMBOL_EXPIRATION_TIME	Date of the symbol trade end (usually used for futures)	SymbolInfoInteger

SYMBOL_FILLING_FOK	This policy means that a deal can be executed only with the specified volume. If the necessary amount of a financial instrument is currently unavailable in the market, the order will not be executed. The required volume can be filled using several offers available on the market at the moment.	SymbolInfoInteger
SYMBOL_FILLING_IOC	In this case a trader agrees to execute a deal with the volume maximally available in the market within that indicated in the order. In case the order cannot be filled completely, the available volume of the order will be filled, and the remaining volume will be canceled. The possibility of using IOC orders is determined at the trade server.	SymbolInfoInteger
SYMBOL_FILLING_MODE	Flags of allowed order filling modes	SymbolInfoInteger
SYMBOL_ISIN	The name of a symbol in the ISIN system (International Securities Identification Number). The International Securities Identification Number is a 12-digit alphanumeric code that uniquely identifies a security. The presence of this symbol property is determined on the side of a trade server.	SymbolInfoString
SYMBOL_LAST	Price of the last deal	SymbolInfoDouble
SYMBOL_LASTHIGH	Maximal Last of the day	SymbolInfoDouble
SYMBOL_LASTLOW	Minimal Last of the day	SymbolInfoDouble
SYMBOL_MARGIN_INITIAL	Initial margin means the amount in the margin currency required for opening a position with the volume of one lot. It is used for checking a client's	SymbolInfoDouble

	assets when he or she enters the market.	
SYMBOL_MARGIN_MAINTENANCE	The maintenance margin. If it is set, it sets the margin amount in the margin currency of the symbol, charged from one lot. It is used for checking a client's assets when his/her account state changes. If the maintenance margin is equal to 0, the initial margin is used.	SymbolInfoDouble
SYMBOL_OPTION_MODE	Option type	SymbolInfoInteger
SYMBOL_OPTION_MODE_EUROPEAN	European option may only be exercised on a specified date (expiration, execution date, delivery date)	SymbolInfoInteger
SYMBOL_OPTION_MODE_AMERICAN	American option may be exercised on any trading day on or before expiry. The period within which a buyer can exercise the option is specified for it	SymbolInfoInteger
SYMBOL_OPTION_RIGHT	Option right (Call/Put)	SymbolInfoInteger
SYMBOL_OPTION_RIGHT_CALL	A call option gives you the right to buy an asset at a specified price	SymbolInfoInteger
SYMBOL_OPTION_RIGHT_PUT	A put option gives you the right to sell an asset at a specified price	SymbolInfoInteger
SYMBOL_OPTION_STRIKE	The strike price of an option. The price at which an option buyer can buy (in a Call option) or sell (in a Put option) the underlying asset, and the option seller is obliged to sell or buy the appropriate amount of the underlying asset.	SymbolInfoDouble
SYMBOL_ORDER_LIMIT	Limit orders are allowed (Buy Limit and Sell Limit)	SymbolInfoInteger
SYMBOL_ORDER_MARKET	Market orders are allowed (Buy and Sell)	SymbolInfoInteger
SYMBOL_ORDER_MODE	Flags of allowed order types	SymbolInfoInteger

SYMBOL_ORDER_SL	Stop Loss is allowed	SymbolInfoInteger
SYMBOL_ORDER_STOP	Stop orders are allowed (Buy Stop and Sell Stop)	SymbolInfoInteger
SYMBOL_ORDER_STOP_LIMIT	Stop-limit orders are allowed (Buy Stop Limit and Sell Stop Limit)	SymbolInfoInteger
SYMBOL_ORDER_TP	Take Profit is allowed	SymbolInfoInteger
SYMBOL_PATH	Path in the symbol tree	SymbolInfoString
SYMBOL_POINT	Symbol point value	SymbolInfoDouble
SYMBOL_SELECT	Symbol is selected in Market Watch	SymbolInfoInteger
SYMBOL_SESSION_AW	Average weighted price of the current session	SymbolInfoDouble
SYMBOL_SESSION_BUY_ORDERS	Number of Buy orders at the moment	SymbolInfoInteger
SYMBOL_SESSION_BUY_ORDERS_VOLUME	Current volume of Buy orders	SymbolInfoDouble
SYMBOL_SESSION_CLOSE	Close price of the current session	SymbolInfoDouble
SYMBOL_SESSION_DEALS	Number of deals in the current session	SymbolInfoInteger
SYMBOL_SESSION_INTEREST	Summary open interest	SymbolInfoDouble
SYMBOL_SESSION_OPEN	Open price of the current session	SymbolInfoDouble
SYMBOL_SESSION_PRICE_LIMIT_MAX	Maximal price of the current session	SymbolInfoDouble
SYMBOL_SESSION_PRICE_LIMIT_MIN	Minimal price of the current session	SymbolInfoDouble
SYMBOL_SESSION_PRICE_SETTLEMENT	Settlement price of the current session	SymbolInfoDouble
SYMBOL_SESSION_SELL_ORDERS	Number of Sell orders at the moment	SymbolInfoInteger
SYMBOL_SESSION_SELL_ORDERS_VOLUME	Current volume of Sell orders	SymbolInfoDouble
SYMBOL_SESSION_TURNOVER	Summary turnover of the current session	SymbolInfoDouble
SYMBOL_SESSION_VOLUME	Summary volume of current session deals	SymbolInfoDouble

SYMBOL_SPREAD	Spread value in points	SymbolInfoInteger
SYMBOL_SPREAD_FLOAT	Indication of a floating spread	SymbolInfoInteger
SYMBOL_START_TIME	Date of the symbol trade beginning (usually used for futures)	SymbolInfoInteger
SYMBOL_SWAP_LONG	Long swap value	SymbolInfoDouble
SYMBOL_SWAP_MODE	Swap calculation model	SymbolInfoInteger
SYMBOL_SWAP_MODE_CURRENCY_DEPOSIT	Swaps are charged in money, in client deposit currency	SymbolInfoInteger
SYMBOL_SWAP_MODE_CURRENCY_MARGIN	Swaps are charged in money in margin currency of the symbol	SymbolInfoInteger
SYMBOL_SWAP_MODE_CURRENCY_SYMBOL	Swaps are charged in money in base currency of the symbol	SymbolInfoInteger
SYMBOL_SWAP_MODE_DISABLED	Swaps disabled (no swaps)	SymbolInfoInteger
SYMBOL_SWAP_MODE_INTEREST_CURRENT	Swaps are charged as the specified annual interest from the instrument price at calculation of swap (standard bank year is 360 days)	SymbolInfoInteger
SYMBOL_SWAP_MODE_INTEREST_OPEN	Swaps are charged as the specified annual interest from the open price of position (standard bank year is 360 days)	SymbolInfoInteger
SYMBOL_SWAP_MODE_POINTS	Swaps are charged in points	SymbolInfoInteger
SYMBOL_SWAP_MODE_REOPEN_BID	Swaps are charged by reopening positions. At the end of a trading day the position is closed. Next day it is reopened by the current Bid price +/- specified number of points (parameters SYMBOL_SWAP_LONG and SYMBOL_SWAP_SHORT)	SymbolInfoInteger
SYMBOL_SWAP_MODE_REOPEN_CURRENT	Swaps are charged by reopening positions. At the end of a trading day the position is closed. Next day it is reopened by the close price +/- specified number of points (parameters	SymbolInfoInteger

	SYMBOL_SWAP_LONG and SYMBOL_SWAP_SHORT)	
SYMBOL_SWAP_ROLLOVER3DAYS	Day of week to charge 3 days swap rollover	SymbolInfoInteger
SYMBOL_SWAP_SHORT	Short swap value	SymbolInfoDouble
SYMBOL_TICKS_BOOKDEPTH	Maximal number of requests shown in Depth of Market . For symbols that have no queue of requests, the value is equal to zero.	SymbolInfoInteger
SYMBOL_TIME	Time of the last quote	SymbolInfoInteger
SYMBOL_TRADE_CALC_MODE	Contract price calculation mode	SymbolInfoInteger
SYMBOL_TRADE_CONTRACT_SIZE	Trade contract size	SymbolInfoDouble
SYMBOL_TRADE_EXECUTION_EXCHANGE	Exchange execution	SymbolInfoInteger
SYMBOL_TRADE_EXECUTION_INSTANT	Instant execution	SymbolInfoInteger
SYMBOL_TRADE_EXECUTION_MARKET	Market execution	SymbolInfoInteger
SYMBOL_TRADE_EXECUTION_REQUEST	Execution by request	SymbolInfoInteger
SYMBOL_TRADE_EXEMODE	Deal execution mode	SymbolInfoInteger
SYMBOL_TRADE_FREEZE_LEVEL	Distance to freeze trade operations in points	SymbolInfoInteger
SYMBOL_TRADE_MODE	Order execution type	SymbolInfoInteger
SYMBOL_TRADE_MODE_CLOSE_ONLY	Allowed only position close operations	SymbolInfoInteger
SYMBOL_TRADE_MODE_DISABLED	Trade is disabled for the symbol	SymbolInfoInteger
SYMBOL_TRADE_MODE_FULL	No trade restrictions	SymbolInfoInteger
SYMBOL_TRADE_MODE_LONG_ONLY	Allowed only long positions	SymbolInfoInteger
SYMBOL_TRADE_MODE_SHORT_ONLY	Allowed only short positions	SymbolInfoInteger
SYMBOL_TRADE_STOPS_LEVEL	Minimal indention in points from the current close price to place Stop orders	SymbolInfoInteger

SYMBOL_TRADE_TICK_SIZE	Minimal price change	SymbolInfoDouble
SYMBOL_TRADE_TICK_VALUE	Value of SYMBOL_TRADE_TICK_VALUE_PROFIT	SymbolInfoDouble
SYMBOL_TRADE_TICK_VALUE_LOSS	Calculated tick price for a losing position	SymbolInfoDouble
SYMBOL_TRADE_TICK_VALUE_PROFIT	Calculated tick price for a profitable position	SymbolInfoDouble
SYMBOL_VOLUME	Volume of the last deal	SymbolInfoInteger
SYMBOL_VOLUME_LIMIT	Maximum allowed aggregate volume of an open position and pending orders in one direction (buy or sell) for the symbol. For example, with the limitation of 5 lots, you can have an open buy position with the volume of 5 lots and place a pending order Sell Limit with the volume of 5 lots. But in this case you cannot place a Buy Limit pending order (since the total volume in one direction will exceed the limitation) or place Sell Limit with the volume more than 5 lots.	SymbolInfoDouble
SYMBOL_VOLUME_MAX	Maximal volume for a deal	SymbolInfoDouble
SYMBOL_VOLUME_MIN	Minimal volume for a deal	SymbolInfoDouble
SYMBOL_VOLUME_STEP	Minimal volume change step for deal execution	SymbolInfoDouble
SYMBOL_VOLUMEHIGH	Maximal day volume	SymbolInfoInteger
SYMBOL_VOLUMELOW	Minimal day volume	SymbolInfoInteger
TENKANSEN_LINE	Tenkan-sen line	Indicators Lines
TERMINAL_BUILD	The client terminal build number	TerminalInfoInteger
TERMINAL_CODEPAGE	Number of the code page of the language installed in the client terminal	TerminalInfoInteger
TERMINAL_COMMONDATA_PATH	Common path for all of the terminals installed on a computer	TerminalInfoString

TERMINAL_COMMUNITY_ACCO UNT	The flag indicates the presence of MQL5.community authorization data in the terminal	TerminalInfoInteger
TERMINAL_COMMUNITY_BALA NCE	Balance in MQL5.community	TerminalInfoDouble
TERMINAL_COMMUNITY_CONN ECTION	Connection to MQL5.community	TerminalInfoInteger
TERMINAL_COMPANY	Company name	TerminalInfoString
TERMINAL_CONNECTED	Connection to a trade server	TerminalInfoInteger
TERMINAL_CPU_CORES	The number of CPU cores in the system	TerminalInfoInteger
TERMINAL_DATA_PATH	Folder in which terminal data are stored	TerminalInfoString
TERMINAL_DISK_SPACE	Free disk space for the MQL5\Files folder of the terminal (agent), MB	TerminalInfoInteger
TERMINAL_DLLS_ALLOWED	Permission to use DLL	TerminalInfoInteger
TERMINAL_EMAIL_ENABLED	Permission to send e-mails using SMTP-server and login, specified in the terminal settings	TerminalInfoInteger
TERMINAL_FTP_ENABLED	Permission to send reports using FTP-server and login, specified in the terminal settings	TerminalInfoInteger
TERMINAL_LANGUAGE	Language of the terminal	TerminalInfoString
TERMINAL_MAXBARS	The maximal bars count on the chart	TerminalInfoInteger
TERMINAL_MEMORY_AVAILABL E	Free memory of the terminal (agent) process, MB	TerminalInfoInteger
TERMINAL_MEMORY_PHYSICAL	Physical memory in the system, MB	TerminalInfoInteger
TERMINAL_MEMORY_TOTAL	Memory available to the process of the terminal (agent), MB	TerminalInfoInteger
TERMINAL_MEMORY_USED	Memory used by the terminal (agent), MB	TerminalInfoInteger
TERMINAL_MQID	The flag indicates the presence of MetaQuotes ID	TerminalInfoInteger

	data for Push notifications	
TERMINAL_NAME	Terminal name	TerminalInfoString
TERMINAL_NOTIFICATIONS_ENABLED	Permission to send notifications to smartphone	TerminalInfoInteger
TERMINAL_OPENCL_SUPPORT	The version of the supported OpenCL in the format of 0x00010002 = 1.2. "0" means that OpenCL is not supported	TerminalInfoInteger
TERMINAL_PATH	Folder from which the terminal is started	TerminalInfoString
TERMINAL_PING_LAST	The last known value of a ping to a trade server in microseconds. One second comprises of one million microseconds	TerminalInfoInteger
TERMINAL_SCREEN_DPI	The resolution of information display on the screen is measured as number of Dots in a line per Inch (DPI).	TerminalInfoInteger
TERMINAL_TRADE_ALLOWED	Permission to trade	TerminalInfoInteger
TERMINAL_X64	Indication of the "64-bit terminal"	TerminalInfoInteger
THURSDAY	Thursday	SymbolInfoInteger , SymbolInfoSessionQuote , SymbolInfoSessionTrade
TRADE_ACTION_DEAL	Place a trade order for an immediate execution with the specified parameters (market order)	MqlTradeRequest
TRADE_ACTION_MODIFY	Modify the parameters of the order placed previously	MqlTradeRequest
TRADE_ACTION_PENDING	Place a trade order for the execution under specified conditions (pending order)	MqlTradeRequest
TRADE_ACTION_REMOVE	Delete the pending order placed previously	MqlTradeRequest
TRADE_ACTION_SLTP	Modify Stop Loss and Take Profit values of an opened position	MqlTradeRequest
TRADE_RETCODE_CANCEL	Request canceled by trader	MqlTradeResult

TRADE_RETCODE_CLIENT_DISABLED_AT	Autotrading disabled by client terminal	MqlTradeResult
TRADE_RETCODE_CONNECTION	No connection with the trade server	MqlTradeResult
TRADE_RETCODE_DONE	Request completed	MqlTradeResult
TRADE_RETCODE_DONE_PARTIAL	Only part of the request was completed	MqlTradeResult
TRADE_RETCODE_ERROR	Request processing error	MqlTradeResult
TRADE_RETCODE_FROZEN	Order or position frozen	MqlTradeResult
TRADE_RETCODE_INVALID	Invalid request	MqlTradeResult
TRADE_RETCODE_INVALID_EXPIRATION	Invalid order expiration date in the request	MqlTradeResult
TRADE_RETCODE_INVALID_FILL	Invalid order filling type	MqlTradeResult
TRADE_RETCODE_INVALID_ORDER	Incorrect or prohibited order type	MqlTradeResult
TRADE_RETCODE_INVALID_PRICE	Invalid price in the request	MqlTradeResult
TRADE_RETCODE_INVALID_STOPS	Invalid stops in the request	MqlTradeResult
TRADE_RETCODE_INVALID_VOLUME	Invalid volume in the request	MqlTradeResult
TRADE_RETCODE_LIMIT_ORDERS	The number of pending orders has reached the limit	MqlTradeResult
TRADE_RETCODE_LIMIT_VOLUME	The volume of orders and positions for the symbol has reached the limit	MqlTradeResult
TRADE_RETCODE_LOCKED	Request locked for processing	MqlTradeResult
TRADE_RETCODE_MARKET_CLOSED	Market is closed	MqlTradeResult
TRADE_RETCODE_NO_CHANGES	No changes in request	MqlTradeResult
TRADE_RETCODE_NO_MONEY	There is not enough money to complete the request	MqlTradeResult
TRADE_RETCODE_ONLY_REAL	Operation is allowed only for live accounts	MqlTradeResult
TRADE_RETCODE_ORDER_CHANGED	Order state changed	MqlTradeResult

TRADE_RETCODE_PLACED	Order placed	MqlTradeResult
TRADE_RETCODE_POSITION_CLOSED	Position with the specified POSITION_IDENTIFIER has already been closed	MqlTradeResult
TRADE_RETCODE_PRICE_CHANGED	Prices changed	MqlTradeResult
TRADE_RETCODE_PRICE_OFF	There are no quotes to process the request	MqlTradeResult
TRADE_RETCODE_REJECT	Request rejected	MqlTradeResult
TRADE_RETCODE_REQUOTE	Requote	MqlTradeResult
TRADE_RETCODE_SERVER_DISABLED_AT	Autotrading disabled by server	MqlTradeResult
TRADE_RETCODE_TIMEOUT	Request canceled by timeout	MqlTradeResult
TRADE_RETCODE_TOO_MANY_REQUESTS	Too frequent requests	MqlTradeResult
TRADE_RETCODE_TRADE_DISABLED	Trade is disabled	MqlTradeResult
TRADE_TRANSACTION_DEAL_ADD	Adding a deal to the history. The action is performed as a result of an order execution or performing operations with an account balance.	MqlTradeTransaction
TRADE_TRANSACTION_DEAL_DELETE	Deleting a deal from the history. There may be cases when a previously executed deal is deleted from a server. For example, a deal has been deleted in an external trading system (exchange) where it was previously transferred by a broker.	MqlTradeTransaction
TRADE_TRANSACTION_DEAL_UPDATE	Updating a deal in the history. There may be cases when a previously executed deal is changed on a server. For example, a deal has been changed in an external trading system (exchange) where it was previously transferred by a broker.	MqlTradeTransaction
TRADE_TRANSACTION_HISTORY_ADD	Adding an order to the history as a result of execution or	MqlTradeTransaction

	cancellation.	
TRADE_TRANSACTION_HISTORY_DELETE	Deleting an order from the orders history. This type is provided for enhancing functionality on a trade server side.	MqlTradeTransaction
TRADE_TRANSACTION_HISTORY_UPDATE	Changing an order located in the orders history. This type is provided for enhancing functionality on a trade server side.	MqlTradeTransaction
TRADE_TRANSACTION_ORDER_ADD	Adding a new open order.	MqlTradeTransaction
TRADE_TRANSACTION_ORDER_DELETE	Removing an order from the list of the open ones. An order can be deleted from the open ones as a result of setting an appropriate request or execution (filling) and moving to the history.	MqlTradeTransaction
TRADE_TRANSACTION_ORDER_UPDATE	Updating an open order. The updates include not only evident changes from the client terminal or a trade server sides but also changes of an order state when setting it (for example, transition from ORDER_STATE_STARTED to ORDER_STATE_PLACED or from ORDER_STATE_PLACED to ORDER_STATE_PARTIAL , etc.).	MqlTradeTransaction
TRADE_TRANSACTION_POSITION	Changing a position not related to a deal execution. This type of transaction shows that a position has been changed on a trade server side. Position volume, open price, Stop Loss and Take Profit levels can be changed. Data on changes are submitted in MqlTradeTransaction structure via OnTradeTransaction handler. Position change (adding, changing or closing), as a result of a deal execution,	MqlTradeTransaction

	does not lead to the occurrence of TRADE_TRANSACTION_POSITION transaction.	
TRADE_TRANSACTION_REQUEST	Notification of the fact that a trade request has been processed by a server and processing result has been received. Only type field (trade transaction type) must be analyzed for such transactions in MqlTradeTransaction structure. The second and third parameters of OnTradeTransaction (request and result) must be analyzed for additional data.	MqlTradeTransaction
TUESDAY	Tuesday	SymbolInfoInteger , SymbolInfoSessionQuote , SymbolInfoSessionTrade
TYPE_BOOL	bool	MqlParam
TYPE_CHAR	char	MqlParam
TYPE_COLOR	color	MqlParam
TYPE_DATETIME	datetime	MqlParam
TYPE_DOUBLE	double	MqlParam
TYPE_FLOAT	float	MqlParam
TYPE_INT	int	MqlParam
TYPE_LONG	long	MqlParam
TYPE_SHORT	short	MqlParam
TYPE_STRING	string	MqlParam
TYPE_UCHAR	uchar	MqlParam
TYPE_UINT	uint	MqlParam
TYPE_ULONG	ulong	MqlParam
TYPE_USHORT	ushort	MqlParam
UCHAR_MAX	Maximal value, which can be represented by uchar type	Numerical Type Constants
UINT_MAX	Maximal value, which can be represented by uint type	Numerical Type Constants

ULONG_MAX	Maximal value, which can be represented by ulong type	Numerical Type Constants
UPPER_BAND	Upper limit	Indicators Lines
UPPER_HISTOGRAM	Upper histogram	Indicators Lines
UPPER_LINE	Upper line	Indicators Lines
USHORT_MAX	Maximal value, which can be represented by ushort type	Numerical Type Constants
VOLUME_REAL	Trade volume	Price Constants
VOLUME_TICK	Tick volume	Price Constants
WEDNESDAY	Wednesday	SymbolInfoInteger , SymbolInfoSessionQuote , SymbolInfoSessionTrade
WHOLE_ARRAY	Means the number of items remaining until the end of the array, i.e., the entire array will be processed	Other Constants
WRONG_VALUE	The constant can be implicitly cast to any enumeration type	Other Constants
